As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU San Diego campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”

Table x: High level summary of campus populations of concern

<tr>
<td>Which population groups have little/limited support networks if impacted by an event?</td>
<td>Students with economic challenges</td>
</tr>
</tbody>
</table>

**Resilience Variables Related to Campus Emergency Management**

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as *Very High, High, Medium, Low*
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as *Yes, No, In Progress, NA*
In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- There are plans for plans for civil unrest though not for racial conflict/racial equity.
- The EOP references the use of calling an Uber or Lyft and other alternative forms of transportation during an evacuation process.
- There is likely to be commuter students from across the border for the Imperial Valley facility.
Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

</tbody>
</table>
**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\(^{210}\) Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\(^{211}\) Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the

major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.212

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitoes that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme cases, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.”

**Landslides**

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied buildings which makes it a function of structural vulnerability and therefore, indirect. The degree of vulnerability to landslides by an individual considered at high risk, or even the

general populations, also depends on human behavior, including many of the traditional social factors that are difficult to measure such as situational awareness, prior knowledge of hazards, and decision-making capabilities.\(^{214}\)

Landslides can result in primary lifeline failures through the loss of roads or power and communication lines. Transportation routes are often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods. Risk from landslide relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity.\(^{215}\) Furthermore, the disabled and the elderly are at

particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.\textsuperscript{216}

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following:\textsuperscript{217} particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.\textsuperscript{218}

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.\textsuperscript{219}

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

21.1 University Profile

University History

Founded in 1899 as a normal school, San Francisco State University became a four-year school in 1930 and received university status as a part of the California State University system in 1972. During the next fifty years, the University played a large role in increasing the size and offerings of the California State University system. It was also the site of several protests during the 1960s and 1970s, including the longest student strike in U.S. history. Today, San Francisco State University includes seven colleges and is classified as a Master’s College by the Carnegie Institute. It is also designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, oversees strategic planning processes, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The San Francisco State Academic Senate, made up of university community members, develops policies and procedures regarding the hiring and support of staff and faculty, business and fiscal matters, University goals and academic standards, and campus development. The Executive Committee of the Academic Senate constitutes its leadership and is made up of three officers, two at-large members, three ASCSU representatives, and the five chairs of the Senate standing committees; all committee members are elected annually. The Standing Committees include: Academic Policies, Curriculum Review and Approval, Faculty Affairs, Strategic Issues, and Student Affairs.

University Mission

“From the heart of a diverse community, San Francisco State University honors roots, stimulates intellectual and personal development, promotes equity, and inspires the courage to lead, create, and innovate.”

The University expresses a commitment to broad access to quality education, diversity, and issues of social justice.

University Location
The San Francisco State University campus encompasses 142 acres two miles from the Pacific Ocean. It is located in the southwestern portion of San Francisco, a major urban area on the northern California coast with a dense population of about 881,000. The three principal cities of the Bay Area - Oakland, San Jose, and San Francisco – represent different employment clusters, including the financial and business industry, heavy industry, and technology industry. The North Bay contributes to California’s agriculture and wine industry. The Bay area’s proximity to the San Andreas and Hayward Faults results in recurrent earthquake activity.

University Population

San Francisco State University typically enrolls approximately 30,000 each semester. In fall 2019, the 28,880-student population was overwhelmingly made up of undergraduate degree seekers, among whom the average age is 22. Asian students make up 30% of the undergraduate students, with Chicano/Mexican American students making up the second most populous group at 27%. About a third of students are first generation to attend college; about half are first generation to earn a bachelor’s degree.

In addition to the student population, the University is home to 3,567 employees, 55% of whom are faculty.

21.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii)(A): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the
types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

**Requirement §201.6(c)(2)(ii)(B):** [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate.

**Requirement §201.6(c)(2)(ii)(C):** [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

**Requirement §201.6(c)(2)(iii):** For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

### 21.3 Hazard Identification and Risk Assessment

**Overview of San Francisco State University History of Hazards**

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

**Hazard Identification**

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s *How-To Series*, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population,
and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 21-1 (following).

Table 21-1: Hazard Identification Determinations

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- Highly Likely- 76%-100% that the hazard would occur annually.
- Likely- 50%-75% that the hazard would occur annually.
- Possible- 11%-49% that the hazard would occur each annually.
- Unlikely- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 21-2 below.)

(Source: Interviews with CSU campus staff at CSU campuses and at CSU Chancellor’s Office.)
Descriptions of Identified Communicable Disease Hazards at San Francisco State University

San Francisco State University (SFSU) has identified one (1) communicable disease hazard that has had the greatest impact on campus – COVID-19. The following is a brief description of the communicable disease hazard at SFSU.

COVID-19 (SARS-CoV-2)

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.  

---

Location of the Hazard

Communicable diseases have the potential to affect the entire San Francisco State University (SFSU) planning area equally. As a result, the communicable disease hazard can be found at both the SFSU main campus and Downtown San Francisco campus; both campuses are located in San Francisco, CA (San Francisco County). The communicable disease hazard can also be found (June through August only) at the SFSU Sierra Nevada Field Campus in Calpine, CA (Sierra County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) all three (3) SFSU locations are at risk of exposure to the communicable disease hazard.

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For SFSU, approximately 13% of its 28,880 enrolled students (or 3,754 students) reside in student housing.

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 21-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

8 California State University. CSU Campus Match. Retrieved 04.30.2021 from: https://www2.calstate.edu/attend/campuses/campus-match/Pages/campus-match.aspx
The Extent of San Francisco State University Communicable Disease Hazards except COVID-19:

Besides COVID-19, there was no information provided on other communicable disease hazards on campus.

The Extent of San Francisco State University COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.  

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 32 cases of COVID-19 at San Francisco State University (SFSU). Most communicable disease data are maintained by at the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically

---

specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 21-5, 21-6, and 21-7 show campus-level and County-level COVID-19 case data for San Francisco State University (SFSU). These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the SFSU campus. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of SFSU students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including SFSU) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.). 14

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 21-7: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 21-9 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

---

Table 21-8: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>

</tbody>
</table>

---

| Risk Group Level III | Anthrax  
| West Nile Virus  
| SARS Virus (Including COVID-19)  
| Tuberculosis  
| Typhus  
| Yellow Fever  
| Hantaviruses  
| Avian Flu | These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone. |

| Risk Group Level IV | H5N1 (Bird Flu)  
| Dengue Hemorrhagic Fever  
| Marburg Virus  
| Ebola Virus  
| Smallpox  
| Lassa Fever  
| Crimean-Congo Hemorrhagic Fever  
| Other Hemorrhagic Diseases | These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release. |

**Probability of Future Occurrence of the Hazard**

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency. Table 21-10 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:
Table 21-9: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the SFSU campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, San Francisco State University had 28,880 students and additional faculty and staff.) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic on the SFSU campus.

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses are at risk of developing an extreme incidence of COVID-19 and may become

---

18 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
“super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. Several CSU campuses saw refund losses surpass $10 million. (See Figure 21-2.)

---

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 21-12) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

</table>
Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity. At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 21-12 below for the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system (including SFSU). In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).
**Drought**

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for San Francisco State University (SFSU) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified throughout San Francisco County and the City of San Francisco which encompass the SFSU campus footprint. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to the campus footprint but occurs on-campus as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously in the state, with 80-100% of the state impacted for 12 of the last 20 years.  

**Extent of the Hazard**

Given the historical occurrence of drought impacts throughout the county and city surrounding the planning area, and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire CSU system-wide planning area equally, the extent of the hazard is variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. That said, the extent of the hazard on campus is reported to be Low.

In addition, drought related land subsidence has occurred statewide and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Though these effects have not been reported on campus, they remain issues of concern for the campus over the long term.

Although the campus planning team identifies the extent of the hazard as Low (qualitatively) which corresponds to D0 – D1 on the Extent scale (below), San Francisco County has experienced more severe drought conditions, including D4 levels during the statewide event from 2012-2017. As such, the campus planning team recognizes that while historic impacts shaping the extent of drought on campus have been minimal, the potential impacts are tied to trends across larger geographic areas, and, therefore, the committee recognizes that the extent of drought on campus has the potential to increase in the future.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

</tbody>
</table>
History of the Hazard

Although drought has not been reported specifically for the campus, drought has been so prevalent in California that its presence is almost continuous. San Francisco County (which encompasses the campus footprint) has experienced several drought periods from 2000-2021, including severe drought from 2012-2017.

Figure 21-3: Periods of Drought in San Francisco County, CA, 2001 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

Source: https://droughtreporter.unl.edu/advancedsearch.aspx

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 29

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 21-4: Periods of Drought in State of California, 2001 – 2021 30

![Drought Periods](image)

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on San Francisco County which surrounds the campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2014-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at

Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.  

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the county surrounding the planning area are often a sub-set of larger and inter-connected regional droughts, and that the (related) historic local impacts provide a sound basis for understanding potential (future) impacts on campus.

The most significant potential impact associated with drought across the SFSU campus planning area is a potential reduction in water availability for the municipal area tied to each campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of SFSU to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of any agricultural research crops and/or field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. However, the wildfire hazard is analyzed separately in this plan.

In reviewing the occurrences of drought for San Francisco County, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to SFSU, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campus. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is

currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area. 33

At present, drought related damage to campus buildings and infrastructure at SFSU has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for SFSU is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including SFSU. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Table 21-13: Summary of Drought Impacts on Water Resources34

<table>
<thead>
<tr>
<th>Resource</th>
<th>Type of Impact</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sea Level</td>
<td>Direct</td>
<td>Sea level is rising and will likely impact coastal areas</td>
</tr>
<tr>
<td>Soil Moisture</td>
<td>Direct</td>
<td>Prolonged dry seasons can lead to decreases in soil moisture; drier vegetation</td>
</tr>
</tbody>
</table>

Vegetation  | Indirect  | Longer and more intense fire season with increased extent of area burned
---|---|---
Stream Conditions  | Direct  | Increases in water temperature; potential effects on fish
Snowpack  | Indirect  | Increases in temperature will lead to decreases in snowpack
Runoff  | Direct  | Warmer temperatures are likely to lead to a shift in peak runoff from spring to winter and a likely decrease in summer base flow
Hydropower  | Indirect  | Decreased summer flows resulting from earlier snowmelt and a shift in peak runoff could affect hydropower generation during summer months
Precipitation  | Direct  | Warmer winter temperatures will result in a greater percentage of precipitation falling as rain rather than as snow
Groundwater  | Indirect  | Reduction in snowpack and extended periods of drought are likely to increase dependency on groundwater

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that SFSU lies within a drought impacted region, it is prudent to extend the **Highly Likely** probability of occurrence to the planning area even though past occurrences and impacts on campus have been minimal.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the SFSU campus.
Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the SFSU planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires. 35

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir. 36

Vulnerability of Populations

Drought vulnerabilities for California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerability measures apply to the students, faculty and staff of the campus.

Property Vulnerability

Drought vulnerabilities for property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree

mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerability measures apply to the properties of the SFSU campus.

**Natural Environment Vulnerability**

Drought vulnerabilities for the campus’ natural environment are primarily drought impacted flora and landscaping. That said, vulnerabilities are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerability on campus and throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for SFSU’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of San Francisco and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better
manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

Identified Data Limitations

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.

**Earthquake**

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas
susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. San Francisco State University is located in the San Francisco Peninsula area of the San Francisco Bay region a mile from the Pacific coastline. The campus is adjacent to Lake Merced on the west side of the university. In general, fault systems surround and traverse throughout the Bay Area and San Francisco including the area of San Francisco State University. Throughout the populated areas of San Francisco and surrounding cities, the ground is saturated with loose sediment. Liquefaction zones rated at moderate susceptibility exist in pockets throughout San Francisco.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 3 miles west of the San Francisco State University campus. In addition to the San Andreas Fault, the San Francisco Peninsula is home to or near additional fault systems with the potential to generate strong ground shaking. The campus is additionally in close proximity to two powerful fault systems. The Hayward Fault traverses south to north
along the western base of the Hayward and Oakland Hills 17 miles east of the San Francisco State University campus. The Calaveras Fault extends south to north 120 miles in length from San Benito County to Contra Costa County 28 miles east of the San Francisco State University campus. The 135-mile-long San Gregorio Fault extends from south of Big Sur to Marin County 7 miles west of the campus. The entire San Francisco Bay Area is saturated with numerous additional faults mostly paralleling the San Andreas Fault to the northwest. These fault systems are located on each side of the campus.

Figure 21-5: Faults near San Francisco State University

Portions of the San Francisco State University campus reside on areas designated to be liquefaction zones. Campus facilities that are potentially located within the liquefaction zone include the Children’s Campus childcare center, the University Police Department, Student Life Events Annexes, Facilities and Service Enterprises, Lot 19 Parking Structure, Central Plant, Warehouse 1, campus Waste Management, College of Science and Engineering, and Field House 1. The liquefaction zones generally appear to extend from Lake Merced in an easterly direction onto the campus and include much of the northern portions of the campus. Liquefaction zones additionally appear throughout the majority of San Francisco and neighboring communities along the coastal edges.
Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity, and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes.

The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:
<table>
<thead>
<tr>
<th>Intensity</th>
<th>Shaking</th>
<th>Description / Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Not felt</td>
<td>Not felt except by a very few under especially favorable conditions.</td>
</tr>
<tr>
<td>II</td>
<td>Weak</td>
<td>Felt only by a few persons at rest, especially on upper floors of buildings.</td>
</tr>
<tr>
<td>III</td>
<td>Weak</td>
<td>Felt quite noticeably by persons indoors, especially on upper floors of buildings. Many people do not recognize it as an earthquake. Standing motor cars may rock slightly. Vibrations similar to the passing of a truck. Duration estimated.</td>
</tr>
<tr>
<td>IV</td>
<td>Light</td>
<td>Felt indoors by many, outdoors by few during the day. At night, some awakened. Dishes, windows, doors disturbed; walls make cracking sound. Sensation like heavy truck striking building. Standing motor cars rocked noticeably.</td>
</tr>
<tr>
<td>V</td>
<td>Moderate</td>
<td>Felt by nearly everyone; many awakened. Some dishes, windows broken. Unstable objects overturned. Pendulum clocks may stop.</td>
</tr>
<tr>
<td>VI</td>
<td>Strong</td>
<td>Felt by all, many frightened. Some heavy furniture moved; a few instances of fallen plaster. Damage slight.</td>
</tr>
<tr>
<td>VII</td>
<td>Very strong</td>
<td>Damage negligible in buildings of good design and construction; slight to moderate in well-built ordinary structures; considerable damage in poorly built or badly designed structures; some chimneys broken.</td>
</tr>
<tr>
<td>VIII</td>
<td>Severe</td>
<td>Damage slight in specially designed structures; considerable damage in ordinary substantial buildings with partial collapse. Damage great in poorly built structures. Fall of chimneys, factory stacks, columns, monuments, walls. Heavy furniture overturned.</td>
</tr>
</tbody>
</table>

Violent

Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb. Damage great in substantial buildings, with partial collapse. Buildings shifted off foundations.

Extreme

Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations. Rails bent.

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 21-7: Earthquake Magnitude and Equivalent Energy Release

Campus facilities are located near liquefaction zones rated as moderately susceptible. In addition, numerous powerful fault systems traverse and surround the campus, and the Bay area has experienced catastrophic events. The impacts of a major earthquake would be felt beyond the campus and have long reaching effects. The risk of casualties and damages would likely extend to the homes and workplaces of members of the campus community including students, staff, and faculty. As such, the planning committee ranks the extent of the hazard as **High**.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Likewise, San Francisco also has a long history of earthquake activity. The entire area of San Francisco and the Bay Area is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The April 18, 1906 San Francisco Earthquake became one of the most well-known earthquakes in California history. The earthquake caused extensive damage to buildings, bridges, water systems, and critical facilities. Damage was experienced well beyond San Francisco including areas such as Monterey and Santa Cruz. 3,000 people were killed and thousands more injured. The San Francisco Earthquake was found to shift the course of northern California rivers. The shaking was felt from Oregon to Los Angeles.

The October 17, 1989 Loma Prieta Earthquake shook a large part of northern California, especially the San Francisco Bay Area. The earthquake caused $5.9 billion in damages, most extensively in San Francisco, the East Bay, and South Bay areas. The earthquake...
resulted in extensive infrastructure damages, 12,000 displaced, 3,757 injuries, and 63 fatalities. The earthquake was provided a federal disaster declaration (DR-845).

**Potential Impacts of the Hazard**

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the San Francisco area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near San Jose could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near San Francisco could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader San Francisco Bay Area region limiting immediate assistance that the campus may normally expect.

Local impacts to the San Francisco State University campus caused by an earthquake could include:

- Injuries and damage related casualties
- Ground rupture
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway and roadway system
- Landslides blocking primary access routes including US 101 and CA SR 1
- Damage to rail lines transiting through San Francisco and surrounding counties
- Structural damage to underground utilities
- Damage to power grid and widespread power outages
- Disruption in water services
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to parking structure facilities
- Structural damage to campus academic and support buildings
- Damage or loss of academic research, documents, electronic storage, art, and literature.
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Gaps in service delivery to vulnerable populations
- Considerable stress and fear among community
- Spontaneous creation of tent cities or outdoor camping on personal property
- Closure or reduction of service to campus operations
- Reduction of campus revenue

**Probability of Future Occurrence of the Hazard**

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the San Francisco Bay Area fault systems surrounding San Francisco is included in the following table.

---

41 City and County of San Francisco Hazard Mitigation Plan, June 2014

The City and County of San Francisco Hazard Mitigation Plan identifies that there is a strong likelihood the San Francisco area will experience a significant earthquake from one of the surrounding major faults in the next 30 years. The Plan further estimates the probability for the faults within the San Francisco Bay Area to produce a Magnitude 6.7 or greater earthquake in the next 30 years is 63%.

Based on the earthquake shaking potential in the San Francisco Bay area, the proximity to the above listed fault systems, and the moderate liquefaction potential that exists throughout the campus, the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of San Francisco State University places the campus in an urban downtown community near residential, commercial, and industrial areas that is densely populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to the San Francisco Bay region generally surround the area and some cross near the San Francisco State University campus. The campus resides in a region that is exposed to fault systems on all sides. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the San Francisco State University campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the city. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases.
Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. This may be heightened along the northern portions of the campus as this area has been identified as being within a liquefaction zone. Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

As the San Francisco State University campus is surrounded by densely populated residential areas, the status of traffic congestion will be needed to be taken into account in making evacuation decisions. The road and freeway network becomes easily congested in normal situations. Bridges serve as a primary access and exit source in and out of San Francisco. The remaining overland routes out of the peninsula are through San Mateo County, these routes can become quickly congested. A major earthquake has the potential for rendering these critical lifelines and supply routes inoperable and forcing the campus community to be self-reliant for a period of time.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $448,726,927.

The table above includes 7 facilities located at the Tiburon based San Francisco State University, Romberg Tiburon Campus. The provided cost estimates for the Romberg Tiburon Campus includes $257,012. However, 2 facilities do not have costs included.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater San Francisco Bay region and the San Francisco State University campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the San Francisco State University campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding San Francisco, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader San Francisco Bay region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue.
Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Erosion

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.”

Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While coastal erosion can happen in any storm, it is more likely during El Nino events, which occur every 5-7 years. For the purpose of this campus-level analysis, the erosion hazard poses an equal risk across these areas of terrain on the San Francisco State University (SFSU) campus with erosion prone characteristics, and can occur in any locations with conducive soil structure and a source of movement, such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. While it is known that such characteristics are present on campus in general, currently no data is available on the discovery or identification of specific erosion-prone locations.

Extent of the Hazard

Erosion is occurring on the Pacific coastline west of SFSU. While there is no published scale of severity or extent for this geologic hazard on the SFSU campus, erosion is likely to occur if conditions are favorable. However, even though no historical occurrence of

---

erosion on campus, the planning committee ranks the extent of this hazard as Moderate due to its location near ongoing erosion challenges along the nearby coastal zone.

History of the Hazard

The San Francisco coastline has been continuously eroding and mitigation projects, such as coastline armoring, are being regularly maintained. There have been no erosion occurrences on the SFSU campus.

Potential Impacts of the Hazard

Coastal erosion can result in severe impacts to local infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. That said, with regard to the campus, although no historical events have taken place, it is not known to what extent existing conditions favorable to erosion are present in specific locations. That said, the probability of at least a limited degree of erosion taking place in the future somewhere on the campus is High over the long term but Low on an annual basis. However, conditions could emerge in the future which increase the annual probability, precipitated by climate change, changes in land-use or other factors.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. SFSU’s infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. CSU leadership would consider performing an analysis to identify such at-risk buildings, infrastructure, slopes and soil types in the future.

In the wider San Francisco community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.
Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

Vulnerability Assessment Conclusions

While the ability to predict future erosion on the SFSU campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Heat**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.45

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.46 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.47

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.48 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor

---

47 Ibid.
workers, low-income households, and individuals with certain chronic medical conditions.49

Location of the Hazard

Extreme heat events are a non-spatial hazard, and may occur at the San Francisco State campus.

Extent of the Hazard

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the high 60s to low 70s in the City of San Francisco. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded in downtown San Francisco is 106°F on September 1, 2017. This record was reached during a statewide heat wave when many locations reached all-time high temperatures. Based on mild average maximum temperatures and only two recorded excessive heat events, the planning committee ranks the extent4 of the hazard as Low.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria.50 In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 21-5 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

---

As the heat index rises, so does the potential danger to people and animals. Table 21-21 (following) shows the health hazards associated with extreme heat.

History of the Hazard

Date gathered from the National Centers for Environmental Information (NCEI) Storm Events Database show that there have been two excessive heat events in San Francisco County since 1950:

**September 1, 2017:** This excessive heat event was declared on the same day when San Francisco hit its all-time highest recorded temperature. There were three deaths attributable to this heat event.

**June 10, 2019:** This heat event occurred in the middle of a stretch of excessively hot days in the Bay Area, particularly for the early summer months. San Francisco reached 100° F.

Potential Impacts of the Hazard

San Francisco State may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

Because the City of San Francisco is surrounded on three sides by water, the San Francisco Bay and the Pacific Ocean, the city is well-positioned for moderate temperatures. However, this can make residents more vulnerable to extreme heat events when they do occur, primarily because many residential units in San Francisco lack air conditioning.\(^{52}\)

Given the increasing number of extreme heat events in California, possibly including San Francisco, it is Possible that the hazard will occur annually in the future.

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme

\(^{52}\) Hazards and Climate Resilience Plan. 4.7 Extreme Heat. Print. Retrieved 01.28.21 from: https://onesanfrancisco.org/hazard/overview
heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result. This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

The San Francisco State Emergency Procedures Handbook does not profile extreme or excessive heat as a campus hazard, nor does it mention the risk of power outages during a prolonged heat wave. However, the City of San Francisco’s comprehensive Hazards and Climate Resilience Plan specifically profiles extreme heat as a growing hazard and projects that by 2100, the city may experience as many as 90 extremely hot days per year. In addition, one of the City’s main mitigation strategies is to develop redundant and resilient electric power capacity, both to avoid severe power outages (as a result of PSPS or due to severe strain on the power grid) as well as to increase the response time after an emergency incident.

As this is a hazard that the campus may experience with increasing regularity, the campus may want to consider strategies to increase its ability to handle the risks and vulnerabilities.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the San Francisco State campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Central California has warmed about two degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.

---

55 Ibid
Cold

Description of the Hazard

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.57

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.58 This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underlying tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes.59 It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases.60 The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6° F. Hypothermia occurs when your body temperature falls below 95° F.61 As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

60 Ibid.
Location of the Hazard

Extreme cold events are a non-spatial hazard, and may occur throughout the San Francisco State campus.

Extent of the Hazard

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in the City of San Francisco are typically in the high 40s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in San Francisco was 27° F on December 11, 1932.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30° F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.62

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure 21-6 (following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow). Given the low frequency of occurrence of freezing temperatures, and a low probability of extreme cold, the planning committee ranks the extent of the hazard as Low.

In 2011, the National Weather Service introduced an experimental program that issued warnings for extreme cold events, independent of other severe weather warnings. The test areas included North and South Dakota and Minnesota. However, in 2012, after a single season of use, the program was abandoned, based on reports of confusion among test audiences.63

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, San Francisco County has had 1 frost/freeze event on December 8, 2009, but no extreme cold hazards. [Records for this hazard were first recorded in 1996].

---

Potential Impacts of the Hazard

Should an extreme cold event occur, San Francisco State might experience impacts due to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

Probability of Future Occurrence of the Hazard

The City of San Francisco has experienced a freeze/frost event, but has never experienced an extreme cold event. Due to the campus’s location in a fairly temperate climate, it is Unlikely that this hazard will occur annually.

Vulnerability to the Hazard

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more likely to suffer illness or death as a result.64 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Neither the campus nor the City of San Francisco have addressed this hazard in their Emergency Response or Hazard Mitigation Plans. Given the infrequency of frost/freeze and extreme cold events in San Francisco, this likely does not increase the campus’s risk or vulnerability to threats.

Estimate of Potential Losses

Based on the previous historical occurrences of extreme cold events, annualized losses are considered to be negligible. In an extreme cold event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future extreme cold events at the San Francisco campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Central California has warmed approximately two degrees on average over the last century, with less rainfall. This may lead to fewer frost/freeze events in the future.65

If an extreme cold event occur, San Francisco State might experience impacts due to cancelled classes. The most likely cause of cold weather for the campus would be a severe winter storm with high winds and rain, which can cause flooding, extended power outages, and road closures.66 The campus regularly monitors weather conditions in order to prepare before a storm hits. If conditions are dangerous, the campus will close and cancel classes.

Power outages are also a concern for the university. The university is on the main power grid and power is supplied by Pacific Gas & Electric (PG&E). A number of facilities are equipped with back-up generators that can allow for partial function during outages, but long-lasting outages may threaten the safety of well water for drinking as well as the use of telecommunication systems.67

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

Flood

Description of the Hazard

66 Sonoma State University Emergency Plan. 11.7 Severe Weather and Environmental Flood. Retrieved 03.24.21 from http://emergency.sonoma.edu/planning-operations/emergency-plan#weather

67 Sonoma State University Emergency Plan. 11.8 Significant Utility Outage. Retrieved 03.24.21 from http://emergency.sonoma.edu/planning-operations/emergency-plan#weather
The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding represents one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water
way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric Rivers**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California, they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Location of the Hazard

San Francisco is located in the San Francisco Bay Area of northern California. San Francisco can experience flooding from overflowing streams and heavy precipitation events in low lying areas of the city. These areas may experience shallow flooding impacting roadways and other areas where drainage is inadequate. The western side of San Francisco is a coastal plain along the Pacific coastline that gradually rises to the east toward the campus. The communities in San Francisco are densely populated with extensive residential neighborhoods. Adjacent to the campus is Lake Merced presenting hydrologic influences on the campus. Immediately to the north of the campus is a commercial zone containing a shopping mall.

The San Francisco State University campus is located in a transition between the low-lying plain that joins with the coastline and the rise of the peninsula hills. The campus is situated in a densely populated urban area. Dense residential neighborhoods are to the south, east, and north of the campus. Lake Merced to the west and the associated water table has influenced high water levels occasionally occurring in the northwestern portions of the campus. The San Francisco State University campus is entirely located in a designated Zone X: Area of Minimal Flood Hazard. The access routes into and out of the campus servicing locations in all directions are also found in areas primarily designated as Zone X.

Extent of the Hazard

The San Francisco State University campus is entirely located in a designated Zone X: Area of Minimal Flood Hazard. The access routes into and out of the campus servicing locations in all directions are also found in areas primarily designated as Zone X: Area of Minimal Flood Hazard. The San Francisco State University, Romberg Tiburon Campus is also entirely located in a designated Zone X: Area of Minimal Flood Hazard. The access
routes into and out of the campus servicing locations in all directions are also found in areas primarily designated as Zone X: Area of Minimal Flood Hazard.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 21-20: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised maps in place on Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, base flood elevations derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
<tr>
<td>Zone AH</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.</td>
</tr>
<tr>
<td>Zone AO</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.</td>
</tr>
</tbody>
</table>
Zone X (shaded)  0.2%  Represents areas between the limits of the 1% annual chance of flooding and 0.2% chance of flooding.

Zone X (unshaded)  Undetermined  Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than 1 foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than 1 square mile, or areas protected from the 1% annual chance flood by levees.

No BFE or depths are shown within this zone.

History of the Hazard

Flooding in San Francisco and the broader San Francisco Bay Area have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the San Francisco State University campus. No history of flood events are reported for the campus. That said, occasional heavy rainfall events can produce isolated pockets of ponding in low lying areas on campus.

Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of

69 City and County of San Francisco Hazard Mitigation Plan, June 2014
the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities,
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Residence halls requiring evacuation and sheltering of occupants
- Threat, inundation, or damage to on campus childcare facilities and occupants
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Inability for campus operations to resume
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

Individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

**Probability of Future Occurrence of the Hazard**

San Francisco is generally not considered to be at high risk from flooding except along coastal areas. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common in the San Francisco Bay Area with winter storms that are saturated with subtropical moisture. The area surrounding the San Francisco State University campus does not generally promote conditions for flood waters to accumulate. There are specific buildings and areas of the campus that have a greater risk for isolated flooding. The San Francisco State University campus is located within a Zone X Special Flood Hazard Area (Area of Minimal Flood Hazard) and not in close proximity to areas with greater flood risk. However, there during high tides or when water levels are higher, additional water enters into Lake Merced
immediately west of the campus. This additional water often causes street flooding along the lower portions of the campus along the western boundary. There is a historic record of isolated urban or street flood events provides a demonstration of potential flood activity.

The probability of future occurrence for flooding is **Unlikely**.

**Vulnerability to the Hazard**

The San Francisco State University campus is subject to the effects of limited and isolated flooding resulting primarily from excessive precipitation and isolated strong storms. Flooding also may result from overflow from Merced Lake. There is limited potential for flooding and damage on campus and surrounding residential and commercial areas of San Francisco due to overflow or damage to municipal drainage systems. The flood control channels and drainage systems that are upstream from the campus have limited storage or volume capacities.

Vulnerability to flooding on the San Francisco State University campus will vary depending on when the flood were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. During rare, severe flood events, members of the campus community may become trapped on campus depending on the level and location of isolated flooding occurring on surface streets. However, in region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

San Francisco State University is in proximity to a variety of industrial and commercial facilities in the surrounding communities. When these facilities are inundated with flood water, the potential for chemical or other hazardous materials release exists presenting possible exposures to individuals from the campus community. These facilities additionally line many of the primary access routes in and out of the campus.

During low probability, severe flood events, some campus buildings and infrastructure might be vulnerable to large-scale flooding if it reaches the university. Campus utilities and communication capabilities might be impacted by flood waters rendering them disabled. An extremely low probability flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. Flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings located in areas of localized flooding.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated
debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $448,726,927. However, it is unlikely for flood to cause destructive losses to the entire campus.

The table above includes 7 facilities located at the Tiburon based San Francisco State University, Romberg Tiburon Campus. The provided cost estimates for the Romberg Tiburon Campus includes $257,012. However, 2 facilities do not have costs included.

Vulnerability Assessment Conclusions
While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets exposed to mostly localized flooding and ponding from overflow of campus creeks or isolated or large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods.

The potential for highly unlikely but severe flooding on the campus generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.
**Hazardous Materials**

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”

Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards:** fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)

---

71 California Department of Industrial Relations. *Worker Safety and Health During Fire Cleanup.* Retrieved 04.18.2021 from: [https://www.dir.ca.gov/dosh/wildfire/Worker-Health-and-Safety-During-Fire-Cleanup.html](https://www.dir.ca.gov/dosh/wildfire/Worker-Health-and-Safety-During-Fire-Cleanup.html)
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from *Natechs* or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. The planning committee indicates that chemicals are located in science labs on campus, and the campus maintains an underground fuel storage tank. Mapping indicates that a hazardous waste site, a rail line and a gas line are approximately ¼ mile from the campus. And a chemical industry site about ½ mile away. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city and county of San Francisco, and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

For the SFSU planning committee, chemicals are managed in campus science labs, and fuel is stored underground. Two events respectively have taken place on campus. Based on these factors, as well as the fairly close proximity of other materials and infrastructure, the extent of the hazard for the SFSU campus is Moderate. That said, it is prudent to

---

consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

According to the campus planning committee, in 2016, a chemical spill incident required the evacuation and shut-down of the science building. In addition, a campus vendor accidentally spilled 2,000 gallons of unleaded fuel into the campus parking lot (date unknown).

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff, and environment on the SFSU campus. With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

Potential Impacts of the Hazard (Natechs)

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including SFSU) are at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

78 2018 California State Hazard Mitigation Plan, section 9.2.
Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the SFSU campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Moderate - the campus has experienced two hazmat events in recent years. In addition, hazardous materials and infrastructure are only ¼ mile away which may increase vulnerability and the probability of a campus-related event. Moreover, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the SFSU campus. As identified by the campus planning committee and on the hazmat map (see section X), the following vulnerabilities are present on campus: chemicals are located in science labs on campus, and the campus maintains an underground fuel storage tank. Mapping indicates that a hazardous waste site, a rail line and a gas line are approximately ¼ mile from the campus. And a chemical industry site about ½ mile away. Gases and chemicals or hazardous waste, if spilled or released, could impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the SFSU leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.
Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including SFSU) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the San Francisco County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the SFSU campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The SFSU planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
Landslide

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may

impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 21-13. As seen on the map, San Francisco State University (SFSU) is not located an area susceptible to landslides, but is located adjacent to such areas.
In San Francisco, landslides are more likely to occur along eroding coastlines. However, the indirect impacts of landslides in the region may cover a larger geographical extent. Based on the location of the campus outside the landslide risk area, the planning committee ranks the extent of the hazard as **Low**, though nearby transportation routes could be affected.

**History of the Hazard**

NOAA recorded one debris flow event in San Francisco County, occurring on February 22, 2019. The landslide occurred a short distance from campus and resulted in one fatality. FEMA declared one major disaster involving landslides and mud flows as a result of a severe storm in 1995.

---

Potential Impacts of the Hazard

SFSU may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels.\(^\text{12}\) Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred rarely in San Francisco and therefore are unlikely to occur in the future. Given the location of the campus beyond landslide risk zones, the planning committee ranks the probability of the landslide hazard for the campus as Unlikely. That said, based on the occasional occurrence of landslides to the east, the probability of experiencing secondary effects of a landslide such as loss of power or transportation disruption is Possible.

Vulnerability to the Hazard

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. That said, the campus’ vulnerability is limited to secondary effects of a landslide such as power outage or transportation disruption.

Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to SFSU.
Vulnerability Assessment Conclusions

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the SFSU campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.13

Power Outage

Description of the Hazard

San Francisco State University (SFSU) is located in the Bay Area of California, within the city (and County) of San Francisco. San Francisco is the fourth most populous city in California, with a population of 883,255; it is also one of the most densely populated cities in California, at 18,569 residents per square mile. Furthermore, San Francisco is part of the 12th-largest metropolitan statistical area in the United States by population (i.e., 4.7 million people).

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly and densely populated areas like San Francisco without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires, and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the SFSU campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of SFSU student residents in on-campus housing would also be affected by a power outage on campus and in the area.

Additionally, a severe outage to San Francisco would also directly affect the campus and the community.
and close restaurants around campus and outside the campus. Additionally, thousands of SFSU student residents in on-campus housing would also be affected by a power outage on campus and in the area.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of **intentional** disruptions are:

- **Planned:** Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- **Unscheduled:** Some intentional disruptions must be done "on the spot" in response to an emergency.
- **Demand-Side Management:** Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- **Load Shedding:** When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

**Location of the Hazard**

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

**Extent of the Hazard**

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:
- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as **Moderate**.

**History of the Hazard**

The City of San Francisco has experienced power outages over time. Their electric utility provider, the Power, Gas and Electric (PG&E) has experienced outages, which have affected the residents of San Francisco over the years. Any major power outages impacting the City of San Francisco in recent years can affect the University campuses.

San Francisco State did not report any power outages in the recent years at San Francisco State, but did advise that the university is within a zone affected by PSPS power outages.

**Potential Impacts of the Hazard**

Instructors, campus residents, staff, and administration rely on electricity for basic operations. During a widespread power failure, it may take anywhere from several hours to days to restore operations if a significant event occurs. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

**Climate Change and Energy Shortage**

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016 - 2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.
With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and San Francisco) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City and County of San Francisco experiences such outages. As such, the probability ranking for the San Francisco area is **Likely**. Although the San Francisco State University campus has not reported any power outage events, it is within a zone affected by Public Safety Power Shutoff (PSPS) events; therefore, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the probability of future occurrences prompting intentional outages and creating unintentional power outages the hazard is high for the county in different areas but not specifically influencing the San Francisco State. Nonetheless, it would serve the campus to ensure to be able to mitigate and cope with an interruption to electrical power.

Although the campus has specific power outage protocols, an outage can impact the operations of the university depending on the severity of the outage. During daytime hours, the University may remain open and business and instructional operations will remain on-going at the maximum extent possible. It will be expected that the areas surrounding the campus, including streetlights, will have also experienced a blackout.

During dark hours staff, students and faculty are to remain on campus for fifteen minutes in the event that power returns. In the event that the power returns business and
instructional operations will resume. If power is not restored, instruction will stop, and business operations will stop for the remainder of the evening.

Classes and university operations and projects utilizing hazardous materials are required to immediately stop to avoid additional hazards.

**Estimate of Potential Losses**

The data provided by San Francisco State does not report any value for potential losses due to power outage.

**Vulnerability Assessment Conclusions**

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at San Francisco State. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept to continue operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

**Identified Data Limitations**

San Francisco State did not report any monetary or life losses due to a power outage.
Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of San Francisco State University (SFSU) or San Francisco County is located within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While C SFSU does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic

eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.\textsuperscript{12}

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As SFSU is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at SFSU.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as \textit{Unlikely}.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For SFSU, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.
Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

SFSU is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

84 State of California Hazard Mitigation Plan, September 2018
California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially influence the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. San Francisco State University (SFSU) and the San Francisco Peninsula are located in a densely populated area of the Bay Area. This area near the university is dominated by urban and suburban communities with limited direct exposures to wildland fire. San Francisco State University has extensive residential neighborhoods to the north, east, and south of campus. The western side of the campus is open parkland, lakes, and coastline.
The San Francisco State University campus is located in the southwestern portion of the City of San Francisco. The campus is 2 miles northwest of the San Bruno Mountains, the closest area designated as having a high fire hazard where there are large areas of hillsides with moderate to heavy vegetative fuels. The campus is not located next to areas with a fire hazard potential making direct impacts by fire on the campus unlikely.

However, the San Francisco State University campus is in a region surrounded by mountains and extensive areas of fire hazards further away. Surrounding the Bay Area are large mountain ranges and hills including the Santa Cruz Mountains, Oakland Hills, Hayward Hills and the mountains of Marin, Sonoma, and Napa Counties. These mountain ranges host forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the Bay Area in the right wind conditions. The geography of the San Francisco Bay and surrounding valleys creates a topography that can capture and direct air pollutants including smoke through the movement of offshore winds. The San Francisco State University campus is located in a region in which wildfire smoke can saturate the air around the campus.

Figure 21-13: Fire Hazard Severity Zones near San Francisco State University

---

Extent of the Hazard

The area immediately surrounding the San Francisco State University campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones, and the campus does not have a history of wildfire activity occurring within proximity to the campus. Although the campus is not surrounded by High fire severity zones, it is surrounded by mountain ranges containing forests with an extensive history of large wildfire development and smoke generation. As a result, the planning committee ranks the extent of the wildfire hazard for the SFSU campus as Moderate.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.
<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel -- especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 4: Very High Danger (VH)</td>
<td>Fires start very easily and spread at a very fast rate</td>
<td>Fires start very easily and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</td>
</tr>
<tr>
<td>COLOR CODE: Orange</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 5: Extreme (E)</td>
<td>Fire situation is explosive and can</td>
<td>Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high</td>

</tbody>
</table>
Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. The San Francisco Bay Area also has a long history of wildfire activity primarily in the foothills and coastal mountains. Wildfires occurring in the Bay Area have resulted in thousands of acres burned and hundreds of millions of dollars in damages.

The area immediately surrounding the San Francisco State University campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The San Francisco campus has experienced multiple days of poor air quality due to fires burning in throughout northern California. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including San Francisco. San Francisco State University personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

88 California Department of Forestry and Fire Protection, Stats and Events, [https://www.fire.ca.gov/stats-events/](https://www.fire.ca.gov/stats-events/)
Potential Impacts of the Hazard

The location of the San Francisco State University campus surrounded by areas of urban development removed from areas with a fire hazard places a minimal direct threat from wildfire to the campus. The potential impacts to wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets

89 City and County of San Francisco Hazard Mitigation Plan, June 2014
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of San Francisco including the campus may be damaged resulting in power outages. Fire-related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the minimal wildfire threat potential in the area surrounding the San Francisco State University campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered **Unlikely**.

Based on the wildfire threat potential in the area surrounding Northern California and San Francisco Bay Area including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered **Possible**.

Vulnerability to the Hazard

The San Francisco State University campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban area of San Francisco. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of San Francisco. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people or the generation of smoke. These effects may spill onto the campus.

Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are remotely possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.
Some areas of particular vulnerability on the campus includes:

- Students and staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC or do not have HVAC will cause limitations in filtering of air during smoke filled days.
- Some buildings are not equipped with HVAC as the local climate typically does not produce extreme temperatures.
- Power outages or brownouts during days with high levels of smoke will limit shelter in place options during heat events in summer.

The greater concerns regarding vulnerabilities to wildfire on San Francisco State University are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the San Francisco Bay Area even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. San Francisco State University students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the San Francisco State University campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would
include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $448,726,927. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher. However, the location of the campus in an urban/suburban setting removed from hazard prone areas makes wildfire related damages unlikely.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in the San Francisco Bay Area; however, wildfire incidents do not pose a direct risk to the San Francisco State University campus. The urban location of the San Francisco State University campus surrounded by densely developed residential and commercial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The students, faculty, and staff of San Francisco State University who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the campus. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.
Additionally, the topography and weather patterns of Northern California often creates conditions that allows for smoke filled air to linger in the valleys of the San Francisco Bay Area with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains and forests some distance away that generate tremendous quantities of smoke present tremendous health related vulnerabilities to members of the campus community. The campus community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, and Lightning)**

**Description of the Hazard**

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding.\(^90\) According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”\(^91\)

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

---

Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including San Francisco State University.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.97

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including San Francisco State), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.98

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.99 The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.100 These storms affect (in varying degrees) all CSU campuses, including San Francisco State.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.101 Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike

98 Retrieved on 07.17.2021 from [https://wrcc.dri.edu/Climate/narrative_ca.php](https://wrcc.dri.edu/Climate/narrative_ca.php)
Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. Severe thunderstorms are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.
- **Wind storm**: marked by high wind with little or no precipitation.
- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.
- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.
- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.
- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially

105 Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\textsuperscript{111}

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: \textit{wind hazards (including tornadoes), hail, and lightning}. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

\textit{Wind} is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\textsuperscript{112} Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”\textsuperscript{113}

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including San Francisco State).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\textsuperscript{114}

\textsuperscript{113} Retrieved on 07.15.2021 from https://forecast.weather.gov/glossary.php?word=wind%20gust
\textsuperscript{114} Retrieved on 07.17.2021 from https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf
Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\textsuperscript{115}

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\textsuperscript{116}

Please note: \textbf{Straight-line wind} is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\textsuperscript{117} However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

Tornadoes

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\textsuperscript{118} This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\textsuperscript{119} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{120}

\textbf{Santa Ana Winds}. A type of wind hazard that is peculiar to Southern California is called a \textit{Santa Ana Wind}. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{121} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal

\textsuperscript{115} Retrieved on 07.17.2021 from \url{https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf}
\textsuperscript{117} Retrieved on 07.15.2021 from \url{https://www.nssl.noaa.gov/education/svrwx101/wind/types/}
\textsuperscript{118} Retrieved on 07.15.2021 from \url{https://www.earthnetworks.com/tornado/}
\textsuperscript{119} Retrieved on 07.15.2021 from \url{https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/}
\textsuperscript{120} Retrieved on 07.15.2021 from \url{https://www.weather.gov/bgm/severe_definitions}
component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{122} (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

Figure 21-15: What Drives a Santa Ana Wind?\textsuperscript{123}

\textbf{Diablo Winds}. The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and

\textsuperscript{122} Retrieved on 07.13.2021 from \url{https://www.weather.gov/safety/wind-mountain-valley}

\textsuperscript{123} Retrieved on 07.14.2021 from \url{https://twitter.com/nwslosangeles/status/933049473034579968}
extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.\footnote{124}

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.\footnote{125} \footnote{126} \footnote{127}

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.\footnote{128} It is roughly round in shape and at least 0.2‘ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.\footnote{129}

\footnote{124 Retrieved on 07.13.2021 from https://www.fireweather.org/diablo-winds}
**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.¹³⁰

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.¹³¹ Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including either at the San Francisco State University main campus or at satellite campus facilities owned by the school. No one area of each campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all San Francisco State campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to San Francisco State campuses reflect those of the surrounding communities and counties. As a result, all assets and people at San Francisco State campuses are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the San Francisco (San Francisco County), Tiburon (Marin County), and Calpine (Sierra County) areas, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

Table 21-26: Beaufort Wind Force Scale

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{135}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the **date** that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 21-27: Fujita Tornado Scale (Pre-February 2007) \(^{136}\)

<table>
<thead>
<tr>
<th>F-Scale Number</th>
<th>Intensity Phrase</th>
<th>Wind Speed</th>
<th>Type of Damage</th>
</tr>

demolished; boxcars pushed over; large trees snapped or uprooted; light object missiles generated.

F3  Severe tornado  158-206 mph  Roof and some walls torn off well-constructed houses; trains overturned; most trees in forest uprooted.

F4  Devastating tornado  207-260 mph  Well-constructed houses leveled; structures with weak foundations blown off some distance; cars thrown and large missiles generated.

F5  Incredible tornado  261-318 mph  Strong frame houses lifted off foundations and carried considerable distances to disintegrate; automobile sized missiles fly through the air in excess of 100 meters; trees debarked; steel reinforced concrete structures badly damaged.

F6  Inconceivable tornado  319-379 mph  These winds are very unlikely. The small area of damage they might produce would probably not be recognizable along with the mess produced by F4 and F5 wind that would surround the F6 winds. Missiles, such as cars and refrigerators would do serious secondary damage that could not be directly identified as F6 damage. If this level is ever achieved, evidence for it might only be found in some manner of ground swirl pattern, for it may never be identifiable through engineering studies.

The table below illustrates the Enhanced Fujita (EF) Scale, currently in use. Tornadoes that have occurred since February, 2007 are classified using the Enhanced Fujita Scale.
<table>
<thead>
<tr>
<th>Enhanced Fujita Category</th>
<th>Wind Speed</th>
<th>Potential Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>EF0</td>
<td>65-85 mph</td>
<td>Light damage. Peels surface off some roofs; some damage to gutters or siding; branches broken off trees; shallow-rooted trees pushed over.</td>
</tr>
<tr>
<td>EF1</td>
<td>86-110 mph</td>
<td>Moderate damage. Roofs severely stripped; mobile homes overturned or badly damaged; loss of exterior doors; windows and other glass broken.</td>
</tr>
<tr>
<td>EF2</td>
<td>111-135 mph</td>
<td>Considerable damage. Roofs torn off well-constructed houses; foundations of frame homes shifted; mobile homes completely destroyed; large trees snapped or uprooted; light-object missiles generated; cars lifted off ground.</td>
</tr>
<tr>
<td>EF3</td>
<td>136-165 mph</td>
<td>Severe damage. Entire stories of well-constructed houses destroyed; severe damage to large buildings such as shopping malls; trains overturned; trees debarked; heavy cars lifted off the ground and thrown; structures with weak foundations blown away some distance.</td>
</tr>
<tr>
<td>EF4</td>
<td>166-200 mph</td>
<td>Devastating damage. Well-constructed houses and whole frame houses completely leveled; cars thrown and small missiles generated.</td>
</tr>
<tr>
<td>EF5</td>
<td>&gt;200 mph</td>
<td>Incredible damage. Strong frame houses leveled off foundations and swept away; automobile-sized missiles fly through the air in excess of 100 m (107 yd); high-rise buildings have significant structural deformation; incredible phenomena will occur.</td>
</tr>
</tbody>
</table>

---

Based on the extent ranking factors identified (above), the planning committee ranks the extent of tornados as **LOW**.

**Extent: Hail**

The National Oceanic and Atmospheric Administration and the Tornado and Storm Research Organization (TORRO) have combined efforts to create the Hailstorm Intensity Scale. Table below provides details of this scale.

Table 21-29: Combined NOAA/TORRO Hailstorm Intensity Scale

<table>
<thead>
<tr>
<th>Size Code</th>
<th>Intensity Category</th>
<th>Typical Hail Diameter</th>
<th>Approximate Size</th>
<th>Typical Damage Impacts</th>
</tr>
</thead>
<tbody>
<tr>
<td>H0</td>
<td>Hard Hail</td>
<td>Up to 0.33”</td>
<td>Pea</td>
<td>No damage</td>
</tr>
<tr>
<td>H1</td>
<td>Potentially Damaging</td>
<td>0.33” – 0.60”</td>
<td>Marble or Mothball</td>
<td>Slight damage to plants and crops</td>
</tr>
<tr>
<td>H2</td>
<td>Potentially Damaging</td>
<td>0.60” – 0.80”</td>
<td>Dime or grape</td>
<td>Significant damage to fruit, crops, and vegetation</td>
</tr>
<tr>
<td>H3</td>
<td>Severe</td>
<td>0.80” – 1.20”</td>
<td>Nickel to Quarter</td>
<td>Severe damage to fruit and crops, damage to glass and plastic</td>
</tr>
</tbody>
</table>

| H4 | Severe | 1.20” – 1.60” | Half Dollar to Ping Pong Ball | Widespread glass damage, vehicle body damage |
| H5 | Destructive | 1.60” – 2.0” | Silver Dollar to Golf Ball | Wholesale destruction of glass, damage to tiled roofs, significant risk of injuries |
| H6 | Destructive | 2.0” – 2.4” | Lime or Egg | Aircraft body dented; brick walls pitted |
| H7 | Very Destructive | 2.4” – 3.0” | Tennis Ball | Severe roof damage, risk of serious injuries |
| H8 | Very Destructive | 3.0” – 3.5” | Baseball to Orange | Severe damage to aircraft body |
Based on those extent ranking factors identified (above), the planning committee ranks the extent of the hail hazard as **LOW**.

**Extent: Lightning**

The National Weather Service (NWS) uses a Lightning Activity Level (LAL) scale to indicate the frequency and character of cloud-to-ground (C/G) lightning. The scale uses a range of 1 – 6, with 6 being the high end of the scale. Table 21-XX provides details of the LAL scale.

Table 21-30: Lightning Activity Level (LAL) Scale

<td>Dry lightning outbreak. (LAL of 3 or greater with majority of storms producing little or no rainfall.)</td>
<td>&gt;15%</td>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events.
– as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no established, objective severity scale for thunderstorms.\textsuperscript{140} \textsuperscript{141} That said, according to the \textit{Glossary of Meteorology} published by the American Meteorological Society (AMS), a thunderstorm is reported as \textit{light}, \textit{medium}, or \textit{heavy} according to following five (5) characteristics:

\begin{itemize}
  \item the nature of the lightning and thunder;
  \item the type and intensity of the precipitation, if any;
  \item the speed and gustiness of the wind;
  \item the appearance of the clouds; and
  \item the effect upon surface temperature.\textsuperscript{142}
\end{itemize}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

\begin{itemize}
  \item \textbf{Airmass Thunderstorm}: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{143}
  \item \textbf{Frontal Thunderstorm}: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{144} or
  \item \textbf{Squall-line Thunderstorm}: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\textsuperscript{145} \textsuperscript{146}
\end{itemize}

\textsuperscript{140} Retrieved on 07.15.2021 from \url{https://www.noaa.gov/explainers/severe-storms}
\textsuperscript{141} Retrieved on 07.15.2021 from \url{https://www.weather.gov/safety/thunderstorm}
Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

**History of the Hazard**

Severe weather hazards have been an annual occurrence in San Francisco County and on the San Francisco State campus. Severe weather hazards have also been an annual occurrence in Marin County and Sierra County, and on the San Francisco State University satellite campus facilities located in those counties. Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type. For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events. To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**San Francisco County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in San Francisco County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

---

- **High Wind**: at least 33 events, or approximately 1.30 events per year\textsuperscript{151}
- **Strong Wind**: at least 43 events, or 1.70 events per year\textsuperscript{152}
- **Thunderstorm Wind**: at least 7 events, or approximately 0.28 events per year\textsuperscript{153}
- **All Wind Hazard events** (excluding Tornadoes): at least 77 events, or approximately 3.04 events per year.\textsuperscript{154} (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in San Francisco County, there have been at least 77 wind hazard events since 1996, excluding tornadoes.\textsuperscript{155} That translates to an approximate average historical frequency of occurrence of **3.04** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 83 events) and simultaneous Database searches of all severe weather hazard events (i.e., 77 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for San Francisco County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{156} When such a discrepancy arises, the more conservative aggregate hazard wind

event value (i.e., 77 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for San Francisco County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that San Francisco County has experienced since 1996 have been costly. While there have been no deaths, there have been 4 injuries, and property damage estimates have totaled approximately $2,520,000; there has been no reported crop damage.\(^{157}\)

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been no reports of tornado hazard events in San Francisco County.\(^{158}\)

**Historical Tornado Hazard Losses for San Francisco County since 1996**

Because no tornado hazard events have occurred in San Francisco County since 1996, there are no tornado-related deaths or injuries, or property or crop damages in the County.\(^{159}\)

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been nine (9) reported events of hail in San Francisco County, which translates to approximately 0.36 hail events per year.\(^{160}\) (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 10 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from San Francisco County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for San Francisco County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that San Francisco County has experienced since 1996 have been negligible. There have been no deaths or injuries, and property and crop damage estimates have each totaled approximately $30.\textsuperscript{161} (Note: The San Diego County hail event erroneously included in the search results for hail events in San Francisco County has accounted for all injuries (i.e., 5) and almost all of the hail crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been seven (7) reported events of lightning in San Francisco County, which translates to approximately **0.28** lightning events per year.\textsuperscript{162}

**Historical Lightning Hazard Losses for San Francisco County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that San Francisco County has experienced since 1996 have been costly. While there have been no deaths or injuries reported, property and crop damage estimates have totaled approximately $120,030 and $30, respectively.\textsuperscript{163}

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

Information obtained from the NCEI Storm Events Database indicates that there have been 93 occurrences of the severe weather hazard in San Francisco County. This translates to **3.67** severe weather hazard occurrences per year.\textsuperscript{164}

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 100 events) and simultaneous Database searches of all severe weather hazard events (i.e., 93 events) may be due to the following factors: (1)

\textsuperscript{161} National Climatic Data Center. Storm Events Database. multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado,”) and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for San Francisco County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{165} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 93 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for San Francisco County since 1996**

According to the NCEI Storm Events Database, the severe weather events that San Francisco County has experienced since 1996 have been costly. While there have been no deaths, there have been four (4) injuries, and property and crop damage estimates have totaled approximately $2,649,000 and $60, respectively.\textsuperscript{166} It is important to note that for all San Francisco County severe weather hazard events recorded on the Storm Events Database, all injuries and approximately 95.1\% of all estimated property damage have been caused by wind hazard events alone. Estimated crop damage (from lightning and hail) has been negligible.

**Marin County**

*Wind Hazards (excluding Tornadoes)*

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Marin County since 1996.\textsuperscript{167} Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\textsuperscript{168}

- **High Wind**: at least 90 events, or approximately 3.55 events per year\textsuperscript{169}

---

According to the NCEI Storm Events Database, the wind hazard events that Marin County has experienced since 1996 have been costly. There have been five (5) deaths and five (5) injuries, and property damage estimates have totaled approximately $3,859,000; there has been no reported crop damage.\textsuperscript{175}

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there has been one (1) reported event of a tornado (i.e., F1/EF1 severity rating) in Marin County, which translates to approximately 0.04 tornado events per year.\textsuperscript{176}

**Historical Tornado Hazard Losses for Marin County since 1996**

According to the NCEI Storm Events Database, the one (1) tornado hazard event that Marin County has experienced since 1996 has been costly. While no death or injuries have been reported, property and crop damage estimates have totaled approximately $200,000 and $5,000, respectively.\textsuperscript{177}

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 12 reported events of hail in Marin County, which translates to approximately 0.47 hail events per year.\textsuperscript{178} (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 13 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Marin County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Marin County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Marin County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damage, property estimates have totaled approximately $50,000.\(^{179}\) (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Marin County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been two (2) reported events of lightning in Marin County, which translates to approximately 0.08 lightning events per year.\(^{180}\)

**Historical Lightning Hazard Losses for Marin County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Marin County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damage, property estimates have totaled approximately $30,300.\(^{181}\)

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

(Marin County)

Information obtained from the NCEI Storm Events Database indicates that there have been 326 occurrences of the severe weather hazard in Marin County. This translates to 12.87 severe weather hazard occurrences per year.\(^{182}\)

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 333 events) and simultaneous Database searches of all severe weather hazard events (i.e., 326 events) may be due to the following factors: (1)
multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Marin County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.  When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 326 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Marin County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Marin County has experienced since 1996 have been costly. There have been five (5) deaths and five (5) injuries, and property and crop damage estimates have totaled approximately $4,090,000 and $5,000, respectively.  It is important to note that for all Marin County severe weather hazard events recorded on the Storm Events Database, all deaths and injuries, as well as 94.4% of all property damage estimates, have been attributed to wind hazard events alone.

**Sierra County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Sierra County since 1996.  Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind:** at least 108 events, or approximately 4.26 events per year

According to the NCEI Storm Events Database, the wind hazard events that Sierra County has experienced since 1996 have been costly. While there have been no deaths or crop damage reported, there have been two (2) injuries, and property damage estimates have totaled approximately $4,411,000.193

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been no reported events of tornadoes in Sierra County.194

**Historical Tornado Hazard Losses for Sierra County since 1996**

Because there have been no reports of tornadoes in Sierra County since 1996, there have been no tornado-related deaths, injuries, property damage, or crop damage.195

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been four (4) reported events of hail in Sierra County, which translates to approximately 0.16 hail events per year.196 (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of five (5) reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Sierra County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Sierra County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Sierra County has experienced since 1996 have been costly. There have been no deaths, injuries,
property damage, or crop damage associated with hail hazard events.\textsuperscript{197} (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Sierra County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

\textit{Lightning}

Information from the NCEI Storm Events Database indicates that since 1996, there has been one (1) reported event of lightning in Sierra County, which translates to approximately 0.04 lightning events per year.\textsuperscript{198}

\textbf{Historical Lightning Hazard Losses for Sierra County since 1996}

According to the NCEI Storm Events Database, the one (1) lightning hazard event that Sierra County had experienced since 1996 was costly, as one (1) death and one (1) injury was attributed to that event; no property or crop damages were reported.\textsuperscript{199}

\textbf{All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database (Sierra County)}

Information obtained from the NCEI Storm Events Database indicates that there have been 116 occurrences of the severe weather hazard in Sierra County. This translates to 4.58 severe weather hazard occurrences per year.\textsuperscript{200}

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 123 events) and simultaneous Database searches of all severe weather hazard events (i.e., 116 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado"; and/or (2) severe weather hazard events such as "Thunderstorm Wind" or “Hail” that are reported for Sierra County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{201} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e.,

\textsuperscript{197} National Climatic Data Center. Storm Events Database. 116 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Sierra County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Sierra County has experienced since 1996 have been costly. There have been one (1) death and three (3) injuries, and property damage estimates have totaled approximately $4,411,000; there has been no reported crop damage.\(^{202}\) *It is important to note that for all Sierra County severe weather hazard events recorded on the Storm Events Database, two (2) of three (3) reported injuries, as well as all property damage estimates, have been attributed to wind hazard events alone.*
Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April.\textsuperscript{203} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textbf{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6 days accounting for 90\% of all occurrences. The remaining 10\% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{204, 205}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Diablo Winds

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^{208}\)

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\(^{209}\)

\(^{209}\) Retrieved on 07.15.2021 from [https://www.fireweather.org/diablo-winds](https://www.fireweather.org/diablo-winds)
Sundowner Winds

Strong sundowner wind events occur approximately **2-3 times per year**. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\(^{211}\)

**Historical Frequency of All Severe Weather Hazards**

Table below shows the average historical frequency of severe weather hazard events for San Francisco County since 1996.)

### Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within all San Francisco State campus areas are at risk from the effects of severe weather hazards.

#### Wind Hazards (Including Tornadoes)

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the San Francisco State campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

#### San Francisco State Main & Downtown Campuses, San Francisco (San Francisco County)

According to the 2020 Hazards and Climate Resilience Plan, strong winter storms bring significant wind gusts occasionally that can cause damage and disruption of services across the region. As a result, wind hazards have a low to moderate significance, and therefore have a minimal to moderate potential impact on San Francisco and (by

---

extension) the San Francisco State Main and Downtown campuses.²¹³ Tornadoes are virtually non-existent in San Francisco, and therefore are considered to have minimal potential impact on San Francisco and (by extension) the San Francisco State Main and Downtown campuses.

**San Francisco State – Romberg Tiburon Campus, Tiburon (Marin County)**

According to the 2019 Marin County Multi-Jurisdiction Local Hazard Mitigation Plan (MCM LHMP), the entire County is affected by wind hazards (excluding tornadoes), but coastal areas are impacted more than inland areas. As a result, wind hazards are considered to be of medium significance, and therefore to have a moderate potential impact on the County and (by extension) on the Romberg Tiburon Campus.²¹⁴ Tornadoes are extremely rare in Marin County and are considered to have a minimal potential impact on the County and (by extension) on the Romberg Tiburon Campus.

**San Francisco State – Sierra Nevada Field Campus, Calpine (Sierra County)**

Sierra County does not have a local hazard mitigation plan. As a result, the potential impacts of wind hazards (including tornadoes) cannot be determined for the County and for the San Francisco State – Sierra Nevada Field Campus.

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

**San Francisco State Main & Downtown Campuses, San Francisco (San Francisco County)**

Hail is not even mentioned in the 2020 Hazards and Climate Resilience Plan. Hail hazards are considered to have low significance, and therefore to have a minimal potential impact on San Francisco and (by extension) the San Francisco State Main and Downtown campuses.²¹⁵

**San Francisco State – Romberg Tiburon Campus, Tiburon (Marin County)**

According to the 2019 Marin County Multi-Jurisdiction Local Hazard Mitigation Plan (MCM LHMP), hail is extremely rare in Marin County and is considered to have a minimal potential impact on the County and (by extension) on the Romberg Tiburon Campus.216

**San Francisco State – Sierra Nevada Field Campus, Calpine (Sierra County).**

Sierra County does not have a local hazard mitigation plan. As a result, the potential impacts of hail hazards cannot be determined for the County and for the San Francisco State – Sierra Nevada Field Campus.

**Lightning**

Lightning strikes the United States about 20-25 million times a year.217 Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.218 Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.219 (Commercial claim payouts for lightning losses for the U.S. were not available.)

**San Francisco State Main & Downtown Campuses, San Francisco (San Francisco County)**

The 2020 Hazards and Climate Resilience Plan only mentions lightning hazards within the context of wildfires. Lightning hazards are considered to have low significance, and therefore to have a minimal potential impact on San Francisco and (by extension) the San Francisco State Main and Downtown campuses.220

**San Francisco State – Romberg Tiburon Campus, Tiburon (Marin County)**

According to the 2019 Marin County Multi-Jurisdiction Local Hazard Mitigation Plan (MCM LHMP), lightning is extremely rare in Marin County and is considered to have a minimal potential impact on the County and (by extension) on the Romberg Tiburon Campus.221

---

San Francisco State – Sierra Nevada Field Campus, Calpine (Sierra County)

Sierra County does not have a local hazard mitigation plan. As a result, the potential impacts of hail hazards cannot be determined for the County and for the San Francisco State – Sierra Nevada Field Campus.

Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year. Future occurrences of such events are projected to increase in both their frequency and intensity.

San Francisco State Main & Downtown Campuses, San Francisco (San Francisco County)

The 2020 Hazards and Climate Resilience Plan states that San Francisco can continue to expect to experience at least one winter wind storm annually that brings strong winds and heavy rains. Also, according to the NCEI Storm Events Database, severe weather wind hazards have occurred in San Francisco County significantly more than once annually – at an average of 3.04 wind hazard events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of San Francisco State’s Main Campus and Downtown Campus areas equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the both the Main and Downtown campuses reflect those of the surrounding community and County.

Based on the data available from both 2020 Hazards and Climate Resilience Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the both San Francisco State campuses located in San Francisco at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for both the Main and Downtown San Francisco State campuses is HIGHLY LIKELY.

San Francisco State – Romberg Tiburon Campus, Tiburon (Marin County)

The 2019 Marin County Multi-Jurisdiction Local Hazard Mitigation Plan (MCM LHMP) states that wind events and associated damages are expected to continue to occur in Marin County several times per year. Also, according to the NCEI Storm Events Database, some of these same severe weather wind hazard events have occurred in Marin County far more than once annually – at an average of 12.28 events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all

areas of the San Francisco State – Romberg Tiburon Campus equally, the smallest
geographic unit of measurement for almost all official severe weather event data is at the
county level. Because the severe weather data used in this assessment do not exist at the
campus level, it is assumed that the severe weather probabilities for the Romberg
Tiburon Campus reflect those of the surrounding community and County.

Based on the data available from both the 2019 Marin County Multi-Jurisdiction Local
Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard
is expected to occur on (or otherwise impact) the Romberg Tiburon Campus at least once
on an annual basis. Therefore, the probability of future occurrence of the severe weather
hazard for San Francisco State – Romberg Tiburon Campus is **HIGHLY LIKELY**.

**San Francisco State – Sierra Nevada Field Campus, Calpine (Sierra County)**

Sierra County does not have a local hazard mitigation plan, and there is no information
available from the County regarding the probability of future occurrence of severe
weather hazards. However, according to the NCEI Storm Events Database, severe weather
wind hazards have occurred in Sierra County significantly more than once annually – at
an average of 4.38 events per year since 1996. Furthermore, while the severe weather
hazard is a non-spatial hazard that affects all areas of the San Francisco State – Sierra
Nevada Field Campus equally, the smallest geographic unit of measurement for almost
all official severe weather event data is at the county level. Because the severe weather
data used in this assessment do not exist at the campus level, it is assumed that the
severe weather probabilities for the San Francisco State – Sierra Nevada Field Campus
reflect those of the surrounding community and County identified in the Table below.

Based on the data available from the NCEI Storm Events Database, the severe weather
hazard is expected to occur on (or otherwise impact) the San Francisco State – Sierra
Nevada Field Campus **at least once on an annual basis**. Therefore, the probability of
future occurrence of the severe weather hazard for the San Francisco State – Sierra
Nevada Field Campus is **HIGHLY LIKELY**.

**San Francisco State University – All Campus Areas**

The probability of future occurrence of the severe weather hazard for all San Francisco
State University campus areas is **HIGHLY LIKELY**.

The following tables show the probabilities of future occurrence for component severe
weather hazards for San Francisco State campuses and facilities in San Francisco, Marin,
and Sierra Counties.
Table 21-34: Severe Weather Hazard Probabilities of Future Occurrence for San Francisco County and San Francisco State University.

Vulnerability to the Hazard

People, structures, and assets on all San Francisco State campuses are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. San Francisco State campuses also have vehicles that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects all San Francisco State campuses. Each of the hazards associated with severe weather can result in losses throughout the planning areas.

All structures located on all San Francisco State campuses are at risk from severe weather. There are approximately 95 campus buildings that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $448,726,927 for 64 buildings, and are unknown for the remaining 31 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

---

The populations at all San Francisco State campuses vary throughout the day and season. As of Fall, 2019, San Francisco State had 28,880 students and 3,401 faculty and staff. All are at risk from severe weather events, with 32,281 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to all San Francisco State campuses. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to San Francisco State.

It is evident that San Francisco State University has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.

21.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU San Francisco campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interviews, the following was asked: “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?” However, as SFSU was early
interview the interview process and question structure for this section were not yet fully defined so responses to the question were not captured.

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.
### Table 21-37: Campus-specific emergency management issues of concern and inclusion in emergency management plans and processes.

**Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities**

The following are interview notes of interest:

- SFSU has a large homeless population supported by an active homelessness committee and the wellness center, which is open for the homeless population to shower and bathe.
- The free food support efforts are managed by housing which is separate from the campus. The HDCS (housing, dining, conference) management team sends representative to the EOC.
- Everyone receives emergency communications, though students with no access to equipment need to go to the library for access.

**Campus High Hazards and Potentially Vulnerable Populations**

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.
In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

### Table 21-38: CSU San Francisco *Highly Likely, Likely and Possible* Hazards

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.227 Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.228 Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

---

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.229

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.
This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 230

**Hazardous Materials**

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease.231 Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.232

231 https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Hazard Mitigation and Emergency Management Planning**

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

22.1 University Profile

University History
San Jose State University was originally known as the Minn’s Evening Normal School in San Francisco in 1857. The school began teaching in San Francisco; its first location, and then in San Jose. As the population in Los Angeles exploded, what eventually became known as the San Jose Normal School opened a branch in LA, which would eventually become known in 1927 as UCLA. By 1934, the San Jose Normal School would change its name to San Jose State College. In 1972, the university would join the CSU system and becoming known as what we know today as, San Jose State University. This would also be a momentous occasion as it would welcome its first female president, Gail Fullerton.

San Jose State University is designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance
The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The President’s Cabinet operates in an advisory capacity. The Cabinet is comprised of senior leaders on campus who provide advice to the president in addressing strategic and operational issues and in pursuing new initiatives.

The President’s Leadership Council is made up of leadership within Academic Affairs, the Academic Senate, and Administration and Finance, Athletics, Diversity, Equity and Inclusion, Information Technology, the President’s Office, Research and Innovation, Student Affairs and finally, University Advancement used at the discretion of the president to seek advice as needed.

University Mission
“In collaboration with nearby industries and communities, SJSU faculty and staff are dedicated to achieving the university’s mission as a responsive institution of the state of California: To enrich the lives of its students, to transmit knowledge to its students along with the necessary skills for applying it in the service of our society, and to expand the base of knowledge through research and scholarship.”
San Jose State University outlines four strategic priorities in support of their goals. The priorities are centered on accountability, a relentless search for knowledge, inclusivity and intellect.

**University Location**

San Jose State calls the infamous Silicon Valley home. The Silicon Valley is the hub of thousands of tech start-up companies and headquarters to the world’s most elite high-tech companies, like Facebook, Apple, Google and Intel. Additionally, San Francisco and the rest of the Bay Area are accessible and if you venture a little further out you can find some of Northern California’s most beautiful nature destinations.

**University Population**

San Jose State University’s student population exceeds 35,400 students, where 27,327 students have enrolled into undergraduate programs and 8,073 students for graduate programs. Asian students make up 34.4% of the student population, followed by Latino students making up 28% of students on campus. An overwhelming percentage of the student population is made up by undergraduate students.

Additionally, a total of 1,945 faculty members teach at SJSU.

### 22.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

**Requirement §201.6(c)(2):** The plan **shall** include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

**Requirement §201.6(c)(2)(i):** [The risk assessment **shall** include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

**Requirement §201.6(c)(2)(ii):** [The risk assessment **shall** include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

**Requirement §201.6(c)(2)(ii):** [The risk assessment] **must** also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

**Requirement §201.6(c)(2)(ii)(A):** The plan **should** describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.
Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

22.3 Hazard Identification and Risk Assessment

Overview of San Jose State University History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 22-1 (following).
Table 22-1: Hazard Identification Determinations

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely** - 76%-100% that the hazard would occur annually.
- **Likely** - 50%-75% that the hazard would occur annually.
- **Possible** - 11%-49% that the hazard would occur each annually.
- **Unlikely** - 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent.¹ They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions.² The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.³

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)⁴

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 22-2 below.)

Descriptions of Identified Communicable Disease Hazards at San José State

San José State University (SJSU) has identified two (2) communicable disease hazards that have had the greatest impact on campus – COVID-19 and H1N1 (Swine Flu). The following are brief descriptions of the communicable disease hazards at SJSU.

COVID-19 (SARS-CoV-2)

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.  

**Influenza (Including sub-type H1N1/Swine Flu)**

Influenza is a viral infection that attacks the respiratory system (i.e., nose, throat, and lungs). Influenza viruses travel through the air in droplets when someone with the infection coughs, sneezes or talks. Influenza is transmitted either by inhaling virus-laden droplets directly, or by coming into physical contact with an object (e.g., telephone or computer keyboard) and then transferring the virus to the eyes, nose or mouth. People with the virus are likely contagious from about a day before symptoms appear until about five days after symptoms begin.

Common signs and symptoms of the flu include: fever, aching muscles, hills and sweats, headache, dry and persistent cough, shortness of breath, tiredness and weakness, runny or stuffy nose, sore throat, and eye pain. (Vomiting and diarrhea are also influenza signs and symptoms, but these are more common in children than in adults.)

Influenza viruses are constantly changing, with new strains appearing regularly. As a result, antibodies against influenza viruses that have been encountered in the past may

---

not offer protection from new influenza strains, as the new strains can be very different viruses from previous strains.  

**H1N1 Flu (Swine Flu)**

The H1N1 flu, commonly known as swine flu, is a type of influenza A virus and is one of several flu viruses strains that can cause the seasonal flu. It is primarily caused by the H1N1 strain of the flu (influenza) virus. Symptoms of the H1N1 flu are the same as those of the seasonal flu.

The H1N1 virus is a combination of viruses from pigs, birds and humans that causes disease in humans. The virus enters your body when you inhale contaminated droplets or transfer live virus from a contaminated surface to your eyes, nose or mouth. It then infects the cells that line your nose, throat and lungs.

**Location of the Hazard**

Communicable diseases have the potential to affect the entire San José State University (SJSU) planning area equally. As a result, the communicable disease hazard can be found at the SJSU campus located in San Jose, CA (Santa Clara County), and at the SJSU Moss Landing Marine Laboratories (MLML) located at Moss Landing, CA (Monterey County). The communicable disease hazard can also be found at the Hammer Theatre, a performing arts venue located in Downtown San Jose and operated by SJSU. Because of the ubiquitous nature of many communicable diseases, SJSU and MLML students, faculty, staff, and visitors, as well as Hammer Theatre patrons, are at risk of exposure to the communicable disease hazard.

**CSU Student Housing Locations and Populations**

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For SJSU, approximately 13% of its 33,282 enrolled students (or 4,327 students) reside in student housing.

---

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 22-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

Figure 22-1: Biosafety Levels (BSLs)\textsuperscript{10}

The Extent of San Jose State University (SJSU) Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Influenza - H1N1 strain at SJSU. Influenza - H1N1 strain would be classified at the BSL-3 containment level.  

The Extent of San Jose State University (SJSU) COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.  

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 208 cases of COVID-19 at SJSU. Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 22-5, 22-6, and 22-7 show campus-level and County-level COVID-19 Case data for San José State (SJSU). These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system (including the SJSU campus). The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population

contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of SJSU students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including SJSU) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

---

Table 22-6: WHO Risk Group Categorization\(^{17}\)

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 22-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 22-7: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>

Ebola Virus  
Smallpox  
Lassa Fever  
Crimean-Congo Hemorrhagic Fever  
Other Hemorrhagic Diseases |
| These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release. |

**Probability of Future Occurrence of the Hazard**

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.
Table 22-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 22-8: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s system-wide probability ranking reflects the ranking at the individual CSU campus level unless noted otherwise.

Table 22-9: Probability of Future Occurrence of Communicable Disease Hazard for CSU Systems

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

**Vulnerability to the Hazard**

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at CSU campuses. CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, San Jose State had 33,282 students and additional faculty and staff.) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic at SJSU.

**Estimate of Potential Losses**

**COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities**

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In

19 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

20 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including SJSU) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities.\(^\text{21}\) The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Table 22-11 below for the economic impact to the SJSU campus). Several CSU campuses saw refund losses surpass $10 million. (See Table 22-12.)

Table 22-10: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs\(^\text{22}\)

---

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 22-12.) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

**Vulnerability Assessment Conclusions**

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable
disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 22-13 below for the “10% outbreak scenario” projections for the SJSU campus and for the entire CSU system.

Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system (including SJSU). In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).
**Dam and Levee Failure**

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtoppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

---

Location of the Hazard

Santa Clara County is home to a variety of flood control facilities and levee systems. The dam facilities are mostly along the base of the various mountains and hills throughout the county. Levees have been constructed along the San Francisco Bay and flood control channels providing community protection. The San Jose State University campus is in proximity to multiple small dams upstream to the south and east of the city. The campus is in proximity to rivers or flood control channels lined with levees.

Figure 22-2: Dams and Levees located near San Jose State University

There are a number of dam facilities in the Santa Cruz Mountains and Diablo Range. The larger facilities include the Leroy Anderson Dam and Coyote Dam located in Santa Clara County on the Coyote Creek. Anderson Lake is a reservoir with the potential holding capacity of 89,073-acre feet of water when full. The San Jose State University campus lies within the dam inundation zones for the Anderson Dam facility in addition to major transportation routes south of the campus are included. The James J Lenihan Dam inundation zone and the Calero Dam inundation zone extend in proximity to the campus.
reaching downtown San Jose but stay west of the campus. The Coyote Dam inundation zone extends along the Coyote Creek east of the campus. All of the above inundation zones affect transportation routes and other critical infrastructure in San Jose affecting access and support services to the campus.

Figure 22-3: Leroy Anderson Dam Breach Inundation Map

Figure 22-4: James J Lenihan Dam Breach Inundation Map

California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
The Coyote Creek drains Anderson Lake and portions of the Diablo Range north towards the San Francisco Bay. A number of creeks and flood control systems feed into Coyote Creek throughout San Jose. The length of Coyote Creek from Anderson Lake to the outlet into the San Francisco Bay is a natural creek channel. The channel is located almost ½ mile east of the San Jose State University campus, is separated from the campus by a densely populated residential neighborhood.

The Guadalupe River is a natural creek channel ¾ mile west of the campus that drains much of the northern face of the Santa Cruz Mountains. The channel feeds into the San Francisco Bay after extending along the west side of downtown San Jose and the San Jose International Airport. The San Jose State University campus is separated from the Guadalupe River by downtown San Jose and the densely developed urban core. The river is not lined with levees and the campus is not within a levee protected zone.

31 California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

The San Jose State University campus lies within the dam inundation zone for the Anderson Dam facility, the largest in the area. In the event of a catastrophic failure of the Anderson dam, the San Jose State University campus is expected to be inundated. In addition, the campus lies fairly close the inundation zones for the Lenihan and Calero dams. The inundation areas are expected to spread water in areas to the west and south from the campus. Additionally, there are multiple transportation corridors that lie within the dam inundation zones that could compromise access, evacuation, and supply routes. Based on the factors above, even though high hazard dams in the area undergo regulated inspections, monitoring and maintenance, the planning committee ranks the extent of the hazard as **Moderate**.

**Extent – Levee Failure**

Levees are used along numerous rivers, irrigation channels, and other waterways throughout Santa Clara County primarily along waterways in the eastern part of the County. The SJSU campus does not lie within a levee flood protected area, although the campus is in proximity to rivers or flood control channels lined with levees. Potentially, the campus community will be affected, as a breach in other areas of San Jose or Santa Clara County may cause flooding and damages to the homes of students, faculty, and

---

staff or to access/supply routes, utilities, or other critical services. Based on these conditions, the planning committee ranks the extent of the levee failure hazard on campus as Low.

History of the Hazard

There are no records of dam or levee failures in areas that present a threat to the San Jose State University campus. Santa Clara County has no record of dam failures:

Potential Impacts of the Hazard

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage

33 Santa Clara Operational Area Hazard Mitigation Plan, September 2017
- Floods generating threats to public health
- Flood generated debris

**Levee Failure Impacts**

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

**Probability of Future Occurrence of the Hazard**

Santa Clara County remains at risk from dam and levee failure. The location of the San Jose State University campus downstream from the Anderson Dam and within a flood protected area demonstrates that the potential exists for future dam issues. The entire San Jose State University campus is located within the Anderson Dam inundation zone. Though as a high hazard dam, the Anderson facility undergoes consistent regulated inspections, monitoring and maintenance. There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on historical experience and occurrences, the likelihood of this hazard is low.

The probability of future occurrence for both dam and levee failures is *Unlikely.*
Vulnerability to the Hazard

Given high priority inspections, monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely even though the campus lies within the Anderson dam inundation zone. As such, the campus is not considered to be subject to a high degree of vulnerability on a daily basis. However, in the unlikely event of a catastrophic failure of the Anderson dam, the effects of flooding to the campus would extreme. With regard to the two other inundation zones in close proximity, the campus effects would most likely be limited to indirect or secondary effects in terms of disruption to regional transportation networks and services, and the amount of time to respond to the needs of the campus community prior to inundation will be limited.

Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations in the event of a low probability, catastrophic event.

Vulnerability to a dam or levee failure on the San Jose State University campus will vary depending on the degree of breach or structural failure and when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.
Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to dam and levee failure are $1,129,789,581. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at San Jose State.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the San Jose State campus, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of Anderson or another dam’s total failure, the consequences would be catastrophic to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.
Drought

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for San Jose State University (SJSU) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified throughout Santa Clara County and the City of San Jose where the SJSU campus is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously in the state, with 80-100% of the state impacted for 12 of the last 20 years.  

**Extent of the Hazard**

Given the historical occurrence of drought throughout the county and city surrounding the planning area, and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire CSU system-wide planning area equally, the extent is variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. That said, the extent of the hazard on campus is reported to be Low.

In addition, drought related land subsidence has occurred statewide and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Though such effects have not been reported on campus, they remain issues of concern for the campus over the long term.

---

Although the campus planning team identifies the extent of the hazard as Low (qualitatively) which corresponds to D0 – D1 on the Extent scale (below), Santa Clara County has experienced more severe drought conditions, including D4 levels during the statewide event from 2012-2017. As such, the campus planning team recognizes that while historic impacts shaping the extent of drought on campus have been minimal, the potential impacts are tied to trends across larger geographic areas, and, therefore, the committee recognizes that the extent of drought on campus has the potential to increase in the future.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor;

History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous. Although no occurrences are reported on campus, according to the US Drought Monitor Time Series data, Santa Clara County (which encompasses the SJSU footprint), has experienced six periods of drought covering 11 years from 2000 – 2021, including the severe statewide event from 2012-2017.

Figure 22-7: Periods of Drought in Santa Clara County, CA, 2001 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-

---

34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 37

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 22-8: Periods of Drought in State of California, 2001 – 202138

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the SJSU campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the

groundwater situation in California "a slow-moving train wreck." Spring snowpack at
Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable
April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since
contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has
contributed to declines in crop values across the state. For example, crops including
cotton, corn silage and barley (the field crop category) fell by 42 percent. 39

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or
societal. This assessment of its impact recognizes that historic occurrences of drought
throughout the county surrounding the planning area are often a sub-set of larger and
inter-connected regional droughts, and that the (related) historic local/county impacts
provide a sound basis for understanding potential (future) impacts on campus.

The most significant potential impact associated with drought across the SJSU campus
planning area is a reduction in water availability for the municipal area tied to the
campus. Other impacts include crop loss and damage to trees and other natural
resources (See Tree Mortality below). The footprint of SJSU to some extent includes
these vulnerable resources based on the campus landscape (trees) and the presence (and
footprint size) of any agricultural research crops and/or field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric
conditions. Wildfires almost always coincide with drought in California, though not
limited to such. 40 However, the wildfire hazard is analyzed separately in this plan.

In reviewing the occurrences of drought for Santa Clara County (which encompasses
CSJSU), the US Drought Monitor and the National Drought Mitigation Center report that
tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though
data sources do not provide data for tree mortality specific to CSJSU, the broad
geographic extent of the impact makes it likely that tree mortality occurred to some
degree on the campuses. Due to the lasting and ongoing effects of drought on the
landscape, trees will continue to be impacted within the municipalities, counties and
regions wherein lies the CSU campus system as long as drought conditions continue.

Given the absence of data, in order for the CSU Committee to assess the impact of tree
mortality, it is useful to view it as a risk sub-set to the probability, location, extent,
severity and duration of the drought hazard within each campus-located municipality,
county and region. Regarding potential impacts, standing dead trees could fall, posing a
risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-
impacted trees become susceptible to diseases and insect infestations (bark beetle)

39 National Oceanic and Atmospheric Administration National Centers for Environmental Information. State
Climate Summaries: California. Retrieved 05.04.2021 from: https://statesummaries.ncics.org/chapter/ca/

40 CAL FIRE Fire and Resource Assessment Program (FRAP). 2017 Assessment. Print. Retrieved 05.05.2021
from: https://frap.fire.ca.gov/assessment/
further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.  

At present, drought related damage to campus buildings and infrastructure at SJSU has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for SJSU is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including SJSU. A reduction of electric power generation and water quality deterioration are also potential impact factors.

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that SJSU lies within a drought impacted region, it is prudent to extend the Highly Likely probability of occurrence to the planning area even though past occurrences and impacts on campus have been minimal.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the SJSU campus.
Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the SJSU planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. 43 In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir. 44

Vulnerability of Populations

Drought vulnerabilities for California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the SJSU campus.

Property Vulnerability

Drought vulnerabilities include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary

drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerability measures apply to the properties of the SJSU campus.

Natural Environment Vulnerability

Drought vulnerabilities for the natural environment on campus are primarily flora and landscaping. Statewide, vulnerabilities are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerabilities on campus and throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

Critical Facilities Vulnerabilities

Drought vulnerabilities for SJSU’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

Estimate of Potential Losses

An estimate of potential losses from drought has not been calculated for the campus or the CSU system. However, drought related losses to the City of San Jose and Santa Clara county, and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

Vulnerability Conclusions

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better
manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

Identified Data Limitations

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

Fault Rupture – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

Liquefaction – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

Subsidence - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local
environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

Location of the Hazard

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. San Jose State University is located in the South Bay area of the San Francisco Bay region. In general, fault systems surround and traverse throughout the Bay Area and Santa Clara County including the area of San Jose State University. Throughout the populated areas of San Jose and surrounding cities, the ground is saturated with sediment eroded from the hills by means of multiple stream channels. Liquefaction zones rated at moderate susceptibility exist in the majority of San Jose including all of downtown.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 12-14 miles west of the San Jose State University campus. In addition to the San Andreas Fault, Santa Clara County is home to or near additional fault systems with the potential to generate strong ground shaking. The campus is additionally in close proximity to a number of powerful fault systems. The Hayward Fault traverses south to north along the western base of the Hayward and Oakland Hills 5 miles east of the San Jose State University campus. The Calaveras Fault extends south to north 120 miles in length from San Benito County to Contra Costa County 7 miles east of the CSU East Bay campus. The 17-mile-long Mission Fault connects the Calaveras Fault with the Hayward Fault 10 miles north of the campus. The Monte Vista Fault extends through the peninsula towards San Francisco 8 miles west of the campus. The Silver Creek Fault is one mile east of the campus traversing through urban portions of San Jose. The entire San Francisco Bay Area is saturated with numerous additional faults mostly paralleling the San Andreas Fault to the northwest. These fault systems are located on each side of the campus.
The entire San Jose State University campus resides on areas designated to be liquefaction zones. All campus facilities are located within the liquefaction zone. The liquefaction zones appear throughout downtown following the valley floor towards the bay. Liquefaction zones additionally appear throughout portions of the neighboring communities of San Jose.

Figure 22-10: Liquefaction Zones in Proximity to San Jose State University

---

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity, and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground
motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

</tr>
</tbody>
</table>

The graph below (Figure 22-11) illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases
in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 22-11: Graph Depicting Earthquake Magnitude and Equivalent Energy Release

The entire San Jose State University campus resides on areas designated to be liquefaction zones. All campus facilities are located within the liquefaction zone. In addition, powerful fault systems traverse and surround the campus, and the area has experienced numerous powerful and damaging events. The impacts of a major earthquake would be felt beyond the campus and have long reaching effects. The risk of casualties and damages would likely extend to the homes and workplaces of members of the campus community including students, staff, and faculty. As such, the planning committee ranks the extent of the hazard as **High**.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural

---

damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Likewise, Santa Clara County also has a long history of earthquake activity. The entire area of Santa Clara County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The April 18, 1906 San Francisco Earthquake became one of the most well-known earthquakes in California history. The earthquake caused extensive damage to buildings, bridges, water systems, and critical facilities. Damage was experienced well beyond San Francisco including areas such as Monterey and Santa Cruz. 3,000 people were killed and thousands more injured. The San Francisco Earthquake was found to shift the course of northern California rivers. The shaking was felt from Oregon to Los Angeles.

The October 17, 1989 Loma Prieta Earthquake shook a large part of northern California, especially the San Francisco Bay Area. The earthquake caused $5.9 billion in damages, most extensively in San Francisco, the East Bay, and South Bay areas. The earthquake resulted in extensive infrastructure damages, 12,000 displaced, 3,757 injuries, and 63 fatalities. The earthquake was provided a federal disaster declaration (DR-845).

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Bay Area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

$^{48}$ Santa Clara County Operational Area Hazard Mitigation Plan, September 2017
Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near San Jose could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near San Jose could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader San Francisco Bay Area region limiting immediate assistance that the campus may normally expect.

Local impacts to the San Jose State University campus caused by an earthquake could include:

- Injuries and damage related casualties
- Ground rupture
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway and roadway system
- Landslides blocking primary access routes including US 101 and CA SR 17
- Damage to rail lines transiting through San Jose
- Structural damage to bridges over waterways and flood control channels
- Damage to power grid and widespread power outages
- Disruption in water services
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to flood control facilities
- Structural damage to campus academic and support buildings
- Damage or loss of academic research, documents, electronic storage, art, and literature.
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Gaps in service delivery to vulnerable populations
- Considerable stress and fear among community
- Spontaneous creation of tent cities or outdoor camping on personal property
- Closure or reduction of service to campus operations
- Reduction of campus revenue

**Probability of Future Occurrence of the Hazard**

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Santa Clara County fault systems surrounding the Santa Clara Valley is included in the following table.

40 Santa Clara County Operational Area Hazard Mitigation Plan, September 2017

The Santa Clara County Operational Area Hazard Mitigation Plan identifies that the region experiences small earthquakes every year. The Plan further estimates the probability for the faults within the San Francisco Bay Area to produce a Magnitude 6.7 or greater earthquake in the next 30 years is 72%.

Based on the earthquake shaking potential in the San Francisco Bay area, the proximity to the above listed fault systems, and the moderate liquefaction potential that exists throughout the campus, the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of San Jose State University places the campus in an urban downtown community near residential, commercial, and industrial areas that is densely populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to the Santa Clara Valley and San Francisco Bay region generally surround the area and some cross near the San Jose State University campus. The campus resides in a region that is exposed to fault systems on all sides. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the San Jose State University campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the city. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend
to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. This may be heightened in the southwestern portions of the campus as this area has been identified as being within a liquefaction zone. As the San Jose State University campus is downstream from dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

The San Francisco Bay Area and San Jose in particular is densely populated and attract numerous commuter employees to the urban core. The road and freeway network becomes easily congested in normal situations. A major earthquake has the potential for rendering these critical lifelines and supply routes inoperable and forcing the campus community to be self-reliant for a period of time.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $1,129,789,581.

Table 22-21: HAZUS Peak Ground Acceleration Zone (PGA) Estimated Losses
The table above includes 3 facilities located at the Moss Landing based San Jose State University, Moss Landing Marine Laboratories. The provided cost estimates for the Moss Landing Marine Laboratories are unknown.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater San Francisco Bay region, the Santa Clara Valley, and the San Jose State University campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the San Jose State University campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding San Jose, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader San Francisco Bay region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

Vulnerabilities will be seen in the physical infrastructure on the campus and the human population of the campus community. Campus infrastructure is vulnerable to severe shaking particularly in areas where the ground is loose or susceptible to liquefaction. Specifically older buildings, masonry constructed buildings, and other structures susceptible to shaking related damage are the most vulnerable. Communication systems,
computer networks, and other electronic systems may be vulnerable when overwhelmed by increased demand during emergencies or by shaking related damages. The people of the campus community are vulnerable to effects of intense shaking in the form of injuries from falling debris, exposure to secondary floods or fires, loss of employment, extreme disaster induced stress, and loss of access to critical services or social contacts.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Erosion**

**Description of the Hazard**

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another”\(^5\) Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable.

**Location of the Hazard**

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any

riverine area. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across those areas of the campus with erosion-prone characteristics. That said, an effort to identify such locations on campus has not been conducted up to this point.

Extent of the Hazard
There is no published scale of severity or extent for this geologic hazard. If conditions are favorable, erosion is likely to occur to some degree over the long term. Given no history of occurrence on the campus and no known locations at risk to erosion, the planning committee ranks the extent of the hazard on the campus as Low.

History of the Hazard
There have been no recorded incidences of erosion on the San Jose State University (SJSU) campus.

Potential Impacts of the Hazard
Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

Probability of Future Occurrence of the Hazard
Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. However, in consideration of the potential extent of erosion, and the unlikely probability of erosion occurring somewhere on campus in the future, the probability is Low over the long term.

Vulnerability to the Hazard
Topography, soil structure, land use, and precipitation are all factors of erosion. SJSU does not have infrastructure and buildings located on steep slopes and does not have recorded instances of erosion.

In the wider San Jose community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

Estimate of Potential Losses
The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.
Vulnerability Assessment Conclusions

While the ability to predict future erosion on the SJSU campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Heat**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.\(^{53}\)

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.\(^{54}\) As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.\(^{55}\)

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.\(^{56}\) In extreme cases, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.\(^{57}\)

**Location of the Hazard**

Extreme heat events are a non-spatial hazard and may occur throughout the San Jose State University campus.

**Extent of the Hazard**

\(^{55}\) Ibid.

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October remain fairly steady in the low 80s in San Jose. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded in San Jose was 119° F on June 14, 2000. Based on 2 extreme heat events, and the probable increase in the number of such events due to climate change, the planning committee ranks the extent of the hazard as Moderate.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to meet the criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 22-12 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

Figure 22-12: Methodology for Determining Heat Index

As the heat index rises, so does the potential danger to people and animals. Table 22-23 (following) shows the health hazards associated with extreme heat.

---

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there has been only two excessive heat events recorded since 1950 and five other heat events.

**June 10, 2019:** This heat event occurred during one of the hottest heat waves ever to hit the Bay Area, with temperatures 20-30 degrees above normal. The temperature in San Jose hit 100° F. There was one death attributable to this excessive heat event.

**June 14, 2000:** According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded in San Jose was 119° F.

Potential Impacts of the Hazard

During an excessive heat event, San Jose State may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact

---

research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

**Probability of Future Occurrence of the Hazard**

The City of San Jose (and Santa Clara County) experienced an excessive heat event in 2000 and 2019. The Santa Clara County Hazard Mitigation Plan considers extreme heat to be a threat to people, pets, and livestock, particularly due to climate change and the increasing number of extremely hot days that Santa Clara County experiences per year.60

According to the scale provided, it is **Possible** that this hazard will occur annually in the future.

**Vulnerability to the Hazard**

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.61 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

San Jose State does not directly address the hazard of extreme heat. The risks of heat illness among campus staff and workers are addressed by the campus’s Office of Environmental Health and Safety. During their orientation, campus staff take a brief course on Heat Illness Prevention.

However, the City of San Jose has a specific Heat Wave Annex as part of its Emergency Operations Plan. The city has contingency plans to open cooling centers, post heat

60 Santa Clara County Operational Area Hazard Mitigation Plan. Projected Number of Extreme Heat Days by Year for OA. Print. Retrieved 01.29.21 from: https://emergencymanagement.sccgov.org/partners

emergency information on the City’s website, notify the public of the hazard, and provide public education materials.\textsuperscript{62}

As this may be a hazard that the campus will experience with increasing regularity, the campus may want to take additional measures in order to properly handle the risks and vulnerabilities.

**Estimate of Potential Losses**

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

**Vulnerability Assessment Conclusions**

While the ability to predict future heat events at the San Jose State campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Central California has warmed about two degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.\textsuperscript{63}

If such changes take place, it will produce a variety of inter-connected vulnerabilities and impacts stemming from each hazard.

**Extreme Cold**

**Description of the Hazard**

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.\textsuperscript{64}

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the

\textsuperscript{64} National Weather Service. *Stay Safe in the Extreme Cold.* Retrieved 01.29.21 from: https://www.weather.gov/dlh/extremecold
frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.65 This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underlying tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes.66 It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases.67 The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6°F. Hypothermia occurs when your body temperature falls below 95°F.68 As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

Location of the Hazard

Extreme cold events are a non-spatial hazard and may occur throughout the San Jose State campus.

Extent of the Hazard

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in the City of San Jose are typically in the low 40s to mid-40s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in the City of San Jose was 19°F on December 22, 1990. Based on no record of extreme cold events and only three frost/freeze events, the planning committee ranks the extent of the hazard on campus as Low.

67 Ibid.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30° F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.69

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure xx (following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow).

In 2011, the National Weather Service introduced an experimental program that issued warnings for extreme cold events, independent of other severe weather warnings. The test areas included North and South Dakota and Minnesota. However, in 2012, after a single season of use, the program was abandoned, based on reports of confusion among test audiences.\textsuperscript{70}

**History of the Hazard**

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, Santa Clara County has had three frost/freeze events, but no extreme cold hazards. \textit{[Records for this hazard were first recorded in 1996].}

**Potential Impacts of the Hazard**

Should an extreme cold event occur, San Jose State might experience impacts due to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

Probability of Future Occurrence of the Hazard

The City of San Jose has experienced frost/freeze events, but has never experienced an extreme cold event. Due to the campus’s location in a fairly temperate climate, it is **Unlikely** that this hazard will occur annually.

Vulnerability to the Hazard

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more likely to suffer illness or death as a result.71 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

San Jose State does not have any specific contingency or emergency plans in case of an extreme cold event. Likewise, excessive/extreme cold is not a profiled hazard in either the City of San Jose Hazard Mitigation Plan/Emergency Operations Plan or in the Santa Clara County Hazard Mitigation Plan. In fact, the Santa Clara County Hazard Mitigation Plan notes that, “Extreme cold weather has not been profiled for the Santa Clara County OA has [sic] its frequency and severity do not warrant assessment (the California State Hazard Mitigation Plan also omitted extreme cold weather as an identified hazard of concern).”72 In an extreme cold or frost/freeze event, power outages can also be a

72 Santa Clara County Operational Area Hazard Mitigation Plan. *Severe Weather, General Background*. Retrieved 03.28.21 from https://emergencymanagement.sccgov.org/partners
concern. However, San Jose State has its own gas-powered power plant that provides 80% of its electrical needs and is not subject to public safety power shut-offs (PSPS) or brown-outs. In a severe power outage, the campus projects that the power plant could provide power to most campus buildings for a period of at least a few days.

Estimate of Potential Losses

Based on the previous historical occurrences of extreme heat events, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future extreme cold events at the San Jose State campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Central California has warmed approximately two degrees on average over the last century, with less rainfall. This may lead to fewer frost/freeze events in the future.73

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

Flood

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and/or adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Floods can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater
amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.
Atmospheric Rivers

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California, they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Location of the Hazard

San Jose is located in Santa Clara County on the southern end of the San Francisco Bay. Santa Clara County can experience flooding from overflowing streams and heavy precipitation events in low lying areas such as San Jose, Santa Clara, and Sunnyvale. These areas often experience shallow flooding impacting roadways and other areas where drainage is inadequate. The northern side of Santa Clara County is a coastal plain adjacent to the San Francisco Bay that gradually rises to the south toward the Santa Cruz Mountains and the Diablo Range. The communities in San Jose are densely populated with extensive residential neighborhoods. Adjacent to the campus is downtown San Jose with heavy commercial land uses including high rise buildings. Within a mile east and west of the campus are industrial zones containing a variety of land uses including chemical facilities and distribution centers shipping different materials.

---

74 National Oceanic and Atmospheric Administration, “What are atmospheric rivers?”, https://www.noaa.gov/stories/what-are-atmospheric-rivers
The San Jose State University campus is located in the low-lying plain that surrounds the San Francisco Bay. The campus is situated in a densely populated downtown area that is ½ mile away from the Coyote Creek to the east and ¾ mile from the Guadalupe River to the west. Both of these waterways drain reservoirs upstream that capture runoff from the hills and mountains that line the Santa Clara Valley.

The San Jose State University campus is entirely located in a designated Zone D: An Area of Undetermined but Possible Flood Threats. The access routes into and out of the campus servicing locations to the north and south are found in designated Zone D: An Area of Undetermined but Possible Flood Threats. Access routes to the west are found in areas designated as Zone X: 0.2% Annual Chance Flood Hazard and Zone AO: 1% Annual Chance Flood Hazard. Access routes to east are found in areas designated as Zone AE: 1% Annual Chance Flood Hazard and Zone D: An Area of Undetermined but Possible Flood Threats.

The San Jose State University, Moss Landing Marine Laboratories campus is entirely located in a designated Zone X: 0.2% Annual Chance Flood Hazard. The access routes into
and out of the campus are found in designated Zone X: 0.2% Annual Chance Flood Hazard and Zone A: 1% Annual Chance Flood Hazard.

Extent of the Hazard

The San Jose State University campus lies within an Undetermined Flood Hazard Areas but outside of levee flood protected areas. Levees protect areas at the base of the foothills and lining flood control channels. Surrounding transportation routes are located in Zones D, X, AE and AO. As such, potential for disruption to campus access exists. That said, the planning committee ranks the extent of the hazard on campus as Low. In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 22-23: Flood Zone Designations and Descriptions

<table>
<thead>

Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, BFEs derived from detailed analyses are shown at selected intervals within these zones.

Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.

Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.

Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.

Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.

History of the Hazard

Flooding in San Jose and the broader San Francisco Bay Area have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the San Jose State University campus. Data on the impact of these events on campus is not available, but, in general, flooding on campus is confines to localized or isolated ponding in low lying areas during heavy rainfall events.

Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities,

\textsuperscript{75} Santa Clara County Operational Area Hazard Mitigation Plan, September 2017
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Residence halls requiring evacuation and sheltering of occupants
- Threat, inundation, or damage to on campus childcare facilities and occupants
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

Santa Clara County is determined to have considerable portions of the county at high risk from flooding. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common in the San Francisco Bay Area with winter storms that are saturated with subtropical moisture. The area surrounding the San Jose State University campus is an urban downtown environment. Flood waters are more likely to occur due to isolated heavy precipitation resulting street flooding. However, the campus is located in an area classified as Zone D (An Area of Undetermined but Possible Flood Threats). A half mile to the northeast is the Coyote Creek zoned as Zone AE Special Flood Hazard Area (Area Inundated by 1% Annual Chance of Flooding) and has a history of flood events. A half mile to the southwest is the Guadalupe Creek and is buffered by Zone X (0.2% of Annual Chance of Flood Hazard). Access in and out of the campus may become compromised in flooding events on or off campus. There are specific buildings and areas of the campus that have a greater risk for isolated flooding. However, the area is subject to isolated urban or street flood events providing a demonstration of potential flood activity.

The probability of future occurrence for flooding on campus is Possible.

Vulnerability to the Hazard
The San Jose State University campus is subject to the effects of localized or isolated flooding resulting primarily from excessive precipitation and isolated strong storms. Flooding also may result from creek overflow from either the Coyote Creek or Guadalupe River. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of San Jose due to overflow or damage to upstream flood control systems. The flood control channels and drainage systems that are upstream from the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the San Jose State University campus will vary depending on when the flood were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. During severe floods, members of the campus community may become trapped on campus depending on the level and locations of isolated flooding occurring on surface streets. However, in rare region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

San Jose State University is in proximity to a variety of industrial and commercial facilities in the surrounding communities. When these facilities are inundated with flood water, the potential for chemical or other hazardous materials release exists presenting possible exposures to individuals from the campus community. These facilities additionally line many of the primary access routes in and out of the campus.

During low probability, severe flood events, some campus buildings and infrastructure might be vulnerable to large-scale flooding if it reaches the university. Campus utilities and communication capabilities might be impacted by flood waters rendering them disabled. A flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. Flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.
Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $1,129,789,581. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located in areas of minimal flooding, the primary vulnerabilities to flood on campus are people and assets exposed to mostly localized flooding from overflow of campus creeks or isolated or large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. The proximity
to the Coyote Creek and Guadalupe River presents an additional flood hazard for the campus.

The potential for highly unlikely, but severe flooding on the campus and surrounding area generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the campus and the surrounding community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Hazardous Materials**

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards:** fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards:** carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters

---

Response may be hindered by a disaster’s impact on the physical environment.\(^8\)

Location of the Hazard

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. The planning committee indicates that chemicals are located in science labs on campus, and the campus stores chlorine for disinfecting its swimming pools. Mapping indicates that numerous hazardous waste sites are very close to the campus, a gas pipeline runs through the middle of campus, and rail lines lie approximately one mile to the south, east and west of campus. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city of San Jose and Santa Clara County, and reflect different types, configurations and scales dispersed across these geographic areas.

---

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

For the SJSU planning committee, chemicals are managed in campus science labs, and chlorine is stored in pool areas. A few small-scale chemical spills have taken place in science labs. Based on these factors, along with the close proximity of hazardous waste sites and the gas pipeline on campus, the extent of the hazard for the SJSU campus is Moderate. That said, it is prudent to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

According to the campus planning committee, a few chemical spills have taken place at science labs but were confined to a small area and did not require evacuation.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type...

of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also to some degree apply to the students, staff and environment on the SJSU campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak\(^3\), which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health.\(^4\) Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – San Jose) is at risk of potential impact from a natural-technological (combined impact) event.

---

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the SJSU campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Moderate - the campus has experienced a few small-scale chemical spills in science labs in recent years. In addition, hazardous materials and a gas pipeline are in close proximity which may increase vulnerability and the probability of a campus-related event. Moreover, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of material or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the SJSU campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: chemicals are located in science labs and the campus stores chlorine for disinfecting its swimming pools; numerous hazardous waste sites closely surround the campus, a gas pipeline runs through the middle of campus, and two rail lines lie approximately one mile to the east and west of campus. Due to their close proximity, gases and chemicals or hazardous waste, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the SJSU leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.
Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including SJSU) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Santa Clara County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the SJSU campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.
Identified Data Limitations

The SJSU planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within its deposition zone, and can result in downstream

---

flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 22-10. Based on Figure 22-10 (below), the SJSU campus is located in an area with a very low degree of susceptibility to landslide.
Extent of the Hazard

In Santa Clara, landslides risk is limited to the steep slopes outside of the metropolitan area. However, the indirect impacts of landslides in the region may cover a larger geographical extent. Additionally, the indirect impacts of landslides in the region may cover a larger geographical extent. Based on the SJSU campus’ location in a low-risk landslide hazard zone, and no history of impacts on or near the campus, the planning committee ranks the extent of the landslide hazard for the campus as **Low**.

History of the Hazard

Landslides have occurred in conjunction with earthquakes and heavy rains in Santa Clara County. NOAA has recorded 23 debris flow events in Santa Clara from 2006 to 2019, almost all of which occurred in the foothills to the south and southwest of Santa Clara.

---

FEMA has declared six major disasters since 1982 that involved landslides, mudslides, or mud flows, all of which were a result of storms or flooding. Earthquake-induced landslides in 1989 disrupted traffic along Highway 17 for a month. No landslides have occurred on or immediately adjacent to the campus.

**Potential Impacts of the Hazard**

San Jose State University (SJSU) may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

**Probability of Future Occurrence of the Hazard**

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in Santa Clara County and therefore are likely to occur in the future. Historically, landslides have occurred infrequently in the City of San Jose and, therefore, are not likely to occur in the future. Given the location of the SJSU campus in a low-risk landslide zone, and the infrequent occurrence of landslides in San Jose, the planning committee ranks the probability of the landslide hazard for the campus as *Unlikely*.

**Vulnerability to the Hazard**

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. The SJSU campus exhibits very few, if any building and infrastructure vulnerabilities due to its location. See the landslide location map in relation to the campus along with landslide severity zones identified. Any population proximal to a landslide when it occurs is vulnerable to its impacts.
Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU San Jose.

Vulnerability Assessment Conclusions

Landslides are not likely to impact the campus, though indirect impacts to campus transportation and utilities are possible. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the SJSU campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.\textsuperscript{13}

Power Outage

Description of the Hazard

San Jose, California is considered the center of the Silicon Valley. It is the third most populous city in California

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly populated areas like San Jose without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the SJSU campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of SJSU student residents in on-campus housing would also be affected by a power outage on campus and in the area.

Additionally, a severe outage to San Jose would also directly affect the campus and the community.
Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions are:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, as a hazard, it has the potential to occur and affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing
the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached.

A power outage could affect the entire area of the campus, including the SJSU athletic fields, classrooms residence halls, administrative offices, virtual, telephonic and radio communications, leading to loss of lighting in campus parking structures, and creating a cascading hazard for commuters as they depart from or arrive to campus in the evening. Additionally, the university is located within proximity of highly utilized thoroughfares for the transportation of goods to throughout California, within one of the busiest areas of the Silicon Valley.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. However, given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as **Moderate**.

**History of the Hazard**

San Jose State reported experiencing power outages and brown outs in recent years. Although the threat is low, the university has gas powered generators to ensure continuity in power. The power outages required generator support to campus facilities, including residence halls and sorority houses near campus. Generators were successful in running over 24 hours during the power outage. The majority of students at San Jose State are commuters (30,000 students). The on-campus power plant provides power to most of the buildings on campus.

**Potential Impacts of the Hazard**

Instructors, campus residents, staff, and administration rely on electricity for basic survival and operations.

During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.
Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and San Jose) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

Probability of Future Occurrence of the Hazard

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City of San Jose and Santa Clara County experience such outages. As such, the probability ranking for the San Jose area is Likely. Since the San Jose State University campus has also recorded power outage events, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

Vulnerability to the Hazard

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.
Estimate of Potential Losses

The data provided by San Jose State does not report any value for potential losses due to power outage.

Vulnerability Assessment Conclusions

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at SJSU. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

San Jose State did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of San Jose State University (SJSU) or Santa Clara County is located within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While SJSU does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California.\textsuperscript{11} The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.\textsuperscript{12}

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As SJSU is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU San Jose.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as **Unlikely**.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For SJSU, there is low vulnerability to the immediate impacts of
volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

**Estimate of Potential Losses**

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the SJSU campus.

**Identified Data Limitations**

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

**Wildfire**

**Description of the Hazard**

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire

---

90 *State of California Hazard Mitigation Plan*, September 2018
growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate at which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. San Jose State University and Santa Clara County are located in a densely populated area of the Bay Area. This area near the university is dominated by downtown urban with limited direct exposures to wildland fire. San Jose State University has extensive residential neighborhoods to the east and south of the campus. The western side of the campus is downtown urban commercial development including high-rise structures.
The San Jose State University campus is located in the central portion of the City of San Jose. The campus is 8 miles north of the Santa Cruz Mountains and 7 miles west of the Diablo Range, the closest areas designated as having a high fire hazard where there are large areas of hillsides with moderate to heavy vegetative fuels. The campus is not located next to areas with a fire hazard potential making direct impacts by fire on the campus unlikely.

However, the San Jose State University campus is in a region surrounded by mountains and extensive areas of fire hazards further away. Surrounding the Bay Area are large mountain ranges and hills including the Santa Cruz Mountains, the Diablo Range, Oakland Hills, Hayward Hills and the mountains of the North Bay Counties. These mountain ranges host forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the Bay Area in the right wind conditions. The geography of the San Francisco Bay, Santa Clara Valley, and surrounding valleys creates a topography that can capture and direct air pollutants including smoke through the movement of offshore winds. The San Jose State University campus is located in a region in which wildfire smoke can saturate the air around the campus.

Figure 22-17: Fire Hazard Severity Zones around San Jose, CA\textsuperscript{91}

Extent of the Hazard

The area immediately surrounding the San Jose State University (SJSU) campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones, and the campus does not have a history of wildfire activity occurring within proximity to the campus. Although the campus is not surrounded by High fire severity zones, it is surrounded by mountain ranges containing forests with an extensive history of large wildfire development and smoke generation. As a result, the planning committee ranks the extent of the wildfire hazard for the SJSU campus as **Moderate**.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.
The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 22-26: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L) COLOR CODE: Green</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M) COLOR CODE: Blue</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>CLASS 3: High Danger (H) COLOR CODE: Yellow</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>CLASS 4: Very High Danger (VH) COLOR CODE: Orange</td>
<td>Fires start very easily and spread at a very fast rate</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</td>
</tr>
</tbody>
</table>

Fire situation is explosive and can result in extensive property damage.

Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. The San Francisco Bay Area also has a long history of wildfire activity primarily in the foothills and coastal mountains. Wildfires occurring in the Bay Area have resulted in thousands of acres burned and hundreds of millions of dollars in damages.

The area immediately surrounding the San Jose State University campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The San Jose campus has experienced multiple days of poor air quality due to fires burning in throughout northern California. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including San Jose. San Jose State University personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

Potential Impacts of the Hazard

The location of the San Jose State University campus surrounded by areas of urban development removed from areas with a fire hazard places a minimal direct threat from wildfire to the campus. The potential impacts to wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations

95 Santa Clara Operational Area Hazard Mitigation Plan, September 2017
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts to the campus resulting from wildfire generated smoke include:
- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of San Jose including the campus may be damaged resulting in power outages. Fire-related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

**Probability of Future Occurrence of the Hazard**

Based on the minimal wildfire threat potential in the area surrounding the San Jose State University campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered **Unlikely**.

Based on the wildfire threat potential in the area surrounding Northern California and San Francisco Bay Area including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered **Possible**.

**Vulnerability to the Hazard**

The San Jose State University campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban area of San Jose. The vulnerabilities to
the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of downtown San Jose. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people or the generation of smoke. These effects may spill onto the campus.

Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are remotely possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

Some areas of particular vulnerability on the campus includes:

- Students and staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC or do not have HVAC will cause limitations in filtering of air during smoke filled days.
- Power outages or brownouts during days with high levels of smoke will limit shelter in place options during heat events in summer.

The greater concerns regarding vulnerabilities to wildfire on San Jose State University are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the San Francisco Bay Area even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. San Jose State University students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the San Jose State University campus will vary depending on when the air quality were to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely,
during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $1,129,789,581. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher. However, the location of the campus in an urban/suburban setting removed from hazard prone areas makes wildfire related damages unlikely.

No Building Value Data Provided* | 25 | Unknown

*Buildings with no value defined are also included in the respective Zones they are found in.

The table above includes 3 facilities located at the Moss Landing based San Jose State University, Moss Landing Marine Laboratories. The provided cost estimates for the Moss Landing Marine Laboratories are unknown.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Santa Clara County; however, wildfire incidents do not pose a direct risk to the San Jose State University campus. The urban location of the San Jose State University campus surrounded by densely
developed residential and commercial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The students, faculty, and staff of San Jose State University who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the campus. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.

Additionally, the topography and weather patterns of Northern California often creates conditions that allows for smoke filled air to linger in the valleys of the San Francisco Bay Area with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains and forests some distance away that generate tremendous quantities of smoke present tremendous health related vulnerabilities to members of the campus community. The campus community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, and Lightning)**

**Description of the Hazard**

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, 

lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”\textsuperscript{97}

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase.\textsuperscript{98} The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific.\textsuperscript{99} Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.\textsuperscript{100}

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California.\textsuperscript{101} On average, areas across California experience

\textsuperscript{98} Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat

\textsuperscript{100} Retrieved on 07.17.2021 from https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions

\textsuperscript{101} Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including San José State University.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including San José State), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage. The SHMP also lists the

103 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
104 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
following types of storms that produce hazardous conditions and potential damage throughout the state of California.\textsuperscript{106} These storms affect (in varying degrees) all CSU campuses, including San José State.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{107} Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.\textsuperscript{108} Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{109} *Severe thunderstorms* are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\textsuperscript{110} \textsuperscript{111}

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.\textsuperscript{112}

- **Wind storm**: marked by high wind with little or no precipitation.\textsuperscript{113}

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\textsuperscript{114}

\textsuperscript{107} Retrieved on 07.14.2021 from https://www.weather.gov/phi/ThunderstormDefinition
\textsuperscript{110} Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
\textsuperscript{111} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.\(^{115}\)

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\(^{116}\)

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\(^{117}\)

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\(^{118}\) Wind gusts are defined as “rapid...
fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including San José State).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.

**Strong Winds**

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.

**Thunderstorm Winds**

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.

Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms. However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

123 Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/
**Tornadoes**

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\(^{124}\) This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\(^{125}\) On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\(^{126}\)

**Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.**

**Santa Ana Winds.** A type of wind hazard that is peculiar to Southern California is called a *Santa Ana Wind*. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\(^{127}\) They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\(^{128}\) (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

What Drives a Santa Ana Wind?

1. High surface pressure builds over the Great Basin region with lower pressure off Southern Cal Coast. (Fall-mid Spring)

2. Air remains relatively cold across the deserts. As the air extends through the mountain passes...it become compressed and warms. (See lower right map) Lower relative humidity also occurs helping to dry out vegetation and can fan any existing fires.

3. Wind speed increases as it squeezes through the mountain and valley canyons. Wind gusts can vary from 45 to 100 mph depending on the strength of the Santa Ana event.

4. Strong winds create turbulence for area flights and can make interstate travel difficult as well as choppy seas for mariners.

Cross Section over the Los Angeles and Ventura County Mountains to the Pacific Ocean

Source: National Weather Service

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.  

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length

---

of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.\textsuperscript{131}  \textsuperscript{132}  \textsuperscript{133}

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.\textsuperscript{134} It is roughly round in shape and at least 0.2' in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.\textsuperscript{135}

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the

surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\textsuperscript{136}

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{137} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

Location of the Hazard

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including either at the San Jose State main campus or at satellite campus facilities owned by the school. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

Extent of the Hazard

Severe weather hazards are non-spatial hazards that potentially affect all San José State campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to San José State campuses reflect those of the surrounding community and County. As a result, all assets and people at San José State campuses are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the San Jose (Santa Clara County) and Moss Landing (Monterey County) areas, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as MODERATE. See each sub-hazard below for the planning committee’s sub-type extent ranking.

\textbf{Wind Hazard: Non-Rotational}

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.\textsuperscript{138} First developed in 1805, it is still used today to estimate wind strengths.\textsuperscript{139}

<tr>
<td></td>
<td>56-63</td>
<td></td>
<td>Very rarely experienced; accompanied by widespread damage.</td>
</tr>
</tbody>
</table>
The air is filled with foam and spray. Sea completely white with driving spray; visibility very seriously affected.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\textsuperscript{141}

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

### Table 22-30: Fujita Tornado Scale (Pre-February 2007) \textsuperscript{142}

</tbody>
</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as **LOW**.
**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no established, objective severity scale for thunderstorms.\(^\text{146}\) \(^\text{147}\) That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light*, *medium*, or *heavy* according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\(^\text{148}\)

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;\(^\text{149}\)
- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\(^\text{150}\)

---

\(^{146}\) Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

\(^{147}\) Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm

**Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).  

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

**History of the Hazard**

Severe weather hazards have been an annual occurrence in Santa Clara County and on the San Diego State main campus. Severe weather hazards have also been an annual occurrence in Monterey County and at the Moss Landing Marine Laboratories campus in Moss Landing, CA. Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type. For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events. To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996.

**Santa Clara County**

*Wind Hazards (excluding Tornadoes)*

---

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Santa Clara County since 1996.\textsuperscript{155} Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind:** at least 128 events, or approximately 5.05 events per year
- **Strong Wind:** at least 319 events, or 12.59 events per year
- **Thunderstorm Wind:** at least 9 events, or approximately ### events per year
- **All Wind Hazard events** (excluding Tornadoes): at least 450 events, or approximately 0.36 events per year. (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Santa Clara County, there have been at least 450 wind hazard events since 1996, excluding tornadoes.\textsuperscript{156} That translates to an approximate average historical frequency of occurrence of \textbf{17.76} wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 456 events) and simultaneous Database searches of all severe weather hazard events (i.e., 450 events) may be due to the following factors: (1) multiple event types in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado;” or (2) severe weather hazard events such as “Thunderstorm Wind” reported for Santa Clara County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{157} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 450 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this error is unknown at this time.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 456 events) and simultaneous Database searches of all severe weather hazard events (i.e., 450 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or

\textsuperscript{156} National Climatic Data Center. Storm Events Database. “Hail/Tornado;” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Santa Clara County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{158} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 450 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Santa Clara County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Santa Clara County has experienced since 1996 have been costly. There have been 7 deaths and 10 injuries, and property damage estimates have totaled approximately $7,400,000; there have been no crop damages reported.

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 5 reported events of tornadoes in Santa Clara County, which translates to approximately \textbf{0.20} tornado events per year. The tornado hazard events reported in Santa Clara County since 1996 have had severity ratings ranging from F0/EF0 to F2/EF2. of tornadoes with a severity rating of F0/EF0.\textsuperscript{159}

**Historical Tornado Hazard Losses for Santa Clara County since 1996**

According to the NCEI Storm Events Database, the five (5) tornado hazard events that Santa Clara County has experienced since 1996 have been costly. While there have been no deaths, there have been two (2) injuries, and property damage estimates have totaled approximately $4,221,000; no crop damage estimates have been reported.\textsuperscript{160}

\textsuperscript{159} National Climatic Data Center. Storm Events Database. Retrieved 07.31.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SAINTA%2BCLARA%3A85&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 33 reported events of hail in Santa Clara County, which translates to approximately **1.34** hail events per year.\(^{161}\) (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 34 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Santa Clara County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Santa Clara County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Santa Clara County has experienced since 1996 have been costly. While there have been no deaths or injuries, property damage estimates have totaled approximately $10,000,000; crop damage estimates have been negligible (i.e., $60).\(^{162}\) (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Santa Clara County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been five (5) reported events of lightning in Santa Clara County, which translates to approximately **0.20** lightning events per year.\(^{163}\)

**Historical Lightning Hazard Losses for Santa Clara County since 1996**

All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database (Monterey County)

Information obtained from the NCEI Storm Events Database indicates that there have been 190 occurrences of the severe weather hazard in Monterey County. This translates to 7.50 severe weather hazard occurrences per year.\textsuperscript{184}

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 197 events) and simultaneous Database searches of all severe weather hazard events (i.e., 190 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado;” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Monterey County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{185} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 190 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical, Aggregated Severe Hazard Losses for Monterey County since 1996

According to the NCEI Storm Events Database, the severe weather events that Monterey County has experienced since 1996 have been costly. There have been 1 death and 1 injury, and property and damage estimates have totaled approximately $1,600,000 and $50, respectively.\textsuperscript{186} However, it is important to note that for all Monterey County severe weather hazard events recorded on the Storm Events Database, all deaths, injuries, and property damage have been attributed to wind hazard events alone.

\textsuperscript{184} National Climatic Data Center. Storm Events Database. Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April.\textsuperscript{187} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6 days accounting for 90\% of all occurrences. The remaining 10\% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{188} \textsuperscript{189}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Diablo Winds

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^{192}\)

---

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{193}

Figure 22-21: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\textsuperscript{194}

\textbf{Sundowner Winds}

Strong sundowner wind events occur approximately \textbf{2-3 times per year}. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\textsuperscript{195}

**Potential Impacts of the Hazard**

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within San Jose State campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the San José State campuses, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

**San José State Main Campus, San Jose (Santa Clara County)**

According to 2017 Santa Clara County Operational Area Hazard Mitigation Plan, one of the most common “severe weather hazard” events that occurs in the County is “high winds” (including tornadoes). This wind hazard is rated in the Plan as having a “medium” or **MODERATE** potential impact on people and property in the County and (by extension) on the San José State main campus.196

---

San José State – Moss Landing Laboratories Campus, Moss Landing (Monterey County)

The only severe weather hazard that is significant enough to be profiled in the 2016 Monterey County Multi-Jurisdictional Hazard Mitigation Plan (MJHMP) is the “Windstorm” hazard; tornadoes are not considered to be significant hazards for the County and therefore are not profiled. (According to the MJHMP, a “windstorm” is a strong wind event either from cyclonic systems and their cold fronts in the winter, or from thermally forced circulations during the spring/summer months (i.e., sea breezes)). Windstorms are considered to be hazards that have a MEDIUM significance for the County; areas of wind hazard susceptibility (and therefore potential impact) within the County differ between the winter and spring/summer months, spreading the impact of the hazard across the year. As a result, wind hazards are considered to have a MODERATE potential impact on the County and (by extension) the San José State – Moss Landing Laboratories campus. Because tornadoes are not considered to be significant hazards for the County, they have MINIMAL potential impact on the County and (by extension) the San José State – Moss Landing Laboratories campus.

Hail

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

San José State Main Campus, San Jose (Santa Clara County)

According to 2017 Santa Clara County Operational Area Hazard Mitigation Plan, hail hazards accompany but are not always present in “severe weather” thunderstorm events. As a result, hail is considered to have a low or MINIMAL potential impact on the County and (by extension) on the San José State main campus.

San José State – Moss Landing Laboratories Campus, Moss Landing (Monterey County)

The 2016 Monterey County Multi-Jurisdictional Hazard Mitigation Plan does not explicitly profile hail, as it is not considered to be a significant severe weather hazard event in Monterey County. As a result, hail hazards are considered to be of LOW significance, and therefore to have a MINIMAL potential impact on the city and (by extension) the San José State – Moss Landing Laboratories campus.  

Lightning

Lightning strikes the United States about 20-25 million times a year. Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured. Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year. (Commercial claim payouts for lightning losses for the U.S. were not available.)

San José State Main Campus, San Jose (Santa Clara County)

According to 2017 Santa Clara County Operational Area Hazard Mitigation Plan, a common “severe weather hazard” event that occurs in the County is the “thunderstorm;” it is a hazard event that is rated by the Plan as having a “medium” impact on people and property in the County. By definition, lightning is a hazard that is always present in a thunderstorm. As a result, lightning is also considered to have a “medium” or MODERATE potential impact on people and property in the County and (by extension) on the San José State main campus.

---

San José State – Moss Landing Laboratories Campus, Moss Landing (Monterey County)

The 2016 Monterey County Multi-Jurisdictional Hazard Mitigation Plan does not explicitly profile lightning as a significant severe weather hazard event in Monterey County, although it is included as a causal event for wildfire hazards. As a result, lightning hazards are considered to be of LOW severe weather significance, and therefore to have a MINIMAL severe weather potential impact on the city and (by extension) the San José State – Moss Landing Laboratories campus.\(^{205}\)

Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year. Future occurrences of such events are projected to increase in both their frequency and intensity.

San José State Main Campus, San Jose (Santa Clara County)

The 2017 Santa Clara County Operational Area Hazard Mitigation Plan states that there is a high “probability of occurrence” (based on likelihood of annual occurrence) for the severe weather hazard. According to the Plan, this means severe weather hazard events are likely to occur within the next 25 years.\(^{206}\) Also, according to the NCEI Storm Events Database, some severe weather hazard events have occurred in Santa Clara County at least once per year; for example, wind hazards have occurred on average 17.76 times per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the San José State main campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the San José State main campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2017 Santa Clara County Operational Area Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the San José State main campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for the San José State main campus is HIGHLY LIKELY.

San José State – Moss Landing Laboratories Campus, Moss Landing (Monterey County)

The 2016 Monterey County Multi-Jurisdictional Hazard Mitigation Plan states that there is between 10% and 100% chance that “Windstorm” hazards (i.e., wind hazards, excluding tornadoes) will occur in the future, and that its probability of future occurrence is “likely.” However, according to the NCEI Storm Events Database, wind hazards have occurred in Monterey County far more than once annually – an average of 6.63 times per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the San José State – Moss Landing Laboratories campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the San José State – Moss Landing Laboratories campus reflect those of the surrounding community and County.

Based on the data available from both 2016 Monterey County Multi-Jurisdictional Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the San José State – Moss Landing Laboratories campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for the San José State – Moss Landing Laboratories campus is HIGHLY LIKELY.

San José State University – All Campus Areas

The probability of future occurrence of the severe weather hazard for all San José State University campus areas is HIGHLY LIKELY.

The following tables show the probabilities of future occurrence for component severe weather hazards for San José State campuses in Santa Clara County and Monterey County.

Vulnerability to the Hazard

People, structures, and assets at both San José State campuses are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. San José State also has vehicles that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects all San José State campus areas. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures at both San José State campuses are at risk from severe weather. There are approximately 90 buildings on the main campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due
to severe weather hazard are $1,129,789,581 for 65 buildings, and are unknown for the remaining 25 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at both San José State campuses varies throughout the day. As of Fall, 2019, San José State had 33,282 students and 3,568 faculty and staff. All are at risk

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to San José State campuses. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to San José State.

It is evident that San José State has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.

**Tsunami**

**Description of the Hazard**

A tsunami is a wave triggered by any form of land displacement along the edge or bottom of an ocean or lake. Land displacement can be in the form of submarine landslides or submarine dip-slip faults. These types of faults cause ruptures that result in seafloor uplift or down-drop. This mass movement translates to a tsunami or gravity wave within the overlying water at the surface.

Tsunamis travel radially outward from the area of initiation. The size of a tsunami is proportional to the mass that moved to generate the tsunami. As a tsunami approaches the shore and the depth of the water column decreases, the energy in the wave pushes the wave crest above the water surface resulting in a larger wave height. Wave runup is the elevation above mean sea level on dry land that a tsunami reaches. Run-up is what causes inundation of coastal areas that are below the run-up height.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement.

both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing severe damage to coastal development. At the shoreline, tsunamis may take the form of a fast-rising tide, a cresting wave, or a bore (a large, turbulent wall-like wave). The bore phenomenon resembles a step-like change in the water level that advances rapidly (from 10 to 60 miles per hour). The first wave is usually followed by several larger and more destructive waves.

**Location of the Hazard:**

Although the main campus is unlikely to face tsunami concerns, the MLML location is at risk. The aquaculture building (7722 Sandholdt Rd, Moss Landing, CA 95039), Norte Facility (Flounder Way, Moss Landing, CA 95039), and the Small Boat and Diving Operations building (7539 Sandholdt Rd, Moss Landing CA). These spaces are within the tsunami hazard area.

**Extent of the Hazard:**

The factors shaping the extent or severity of the hazard are a combination of geophysical forces (the amount of vertical and horizontal motion of the sea floor, the area over which
it occurs, and the efficiency with which energy is transferred from the earth’s crust to the ocean water) and the geographic range of coastal development to be impacted.

More specifically, as a tsunami approaches the shore, wave run-up is the elevation above mean sea level on dry land that a tsunami reaches. A tsunami’s potential severity can be forecasted as a function of the wave’s mass along with the difference between the wave’s run-up height and the ground elevation of the affected coastal location.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

Given the specific asset locations proximate to the tsunami inundation zone, the campus planning committee ranks the extent of the hazard as Moderate.

History of the Hazard:

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. That said, no tsunamis have impacted CSU campus locations.

According to the National Centers for Environmental Information (NCEI), have been eight tsunamis have caused damage to ports and harbors or coastal inundation in California since 1946. The most significant events are as follows:

- In 1964, a tsunami caused by a Magnitude 9.2 earthquake offshore from Alaska resulted in 13 deaths in California and destroyed portions of downtown Crescent City.
- A 2006 tsunami (originating in the Kuril Islands region north of Japan) caused approximately $20 million in damage to Crescent City harbor.
- A 2010 tsunami (originating offshore from Chile) caused millions of dollars in damage to ports and harbors in the state.
- A tsunami in 2011 (caused by a Magnitude 9.0 earthquake offshore of Japan) killed one person at the mouth of the Klamath River and caused up to $100 million of damage to 27 ports, harbors, and marinas throughout the State. The most damage occurred in Crescent City, Santa Cruz and Moss Landing harbors and a federal disaster was declared in Del Norte, Santa Cruz, and

---

Monterey Counties. Both Crescent City and Santa Cruz harbors sustained damage to all docks, and oil spills and water/sediment contamination that resulted from sunk or damaged boats. Because recovery efforts in these two harbors took several years to complete, both harbors incurred business/economic losses that have been difficult to recapture.

In addition, the Worldwide Tsunami Database, www.ngdc.noaa.gov) provides information on tsunami run-up levels and earthquake magnitude factors. Although data for the most recent events is not available, additional (earlier) tsunami events are recorded.

</table>

Potential Impacts of the Hazard:

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing total devastation to coastal development.

The configuration of the coastline, the shape of the ocean floor, and the characteristics of advancing waves play important roles in the destructiveness of the waves. Bays, sounds,
inlets, rivers, streams, offshore canyons, islands, and flood control channels may cause various effects that alter the level of damage. Offshore canyons can focus tsunami wave energy, and islands can filter the energy. It has been estimated that a tsunami wave entering a flood control channel could reach a mile or more inland, especially if it enters at high tide. The orientation of the coastline determines whether the waves strike head-on or are refracted from other parts of the coastline.

Potential impacts to the campus are specific to the aquaculture building, the Norte Facility, and the Small Boat and Diving Operations buildings in Moss Landing. Tsunamis that impact both harbors and communities also can produce free-floating debris hazards and environmental contamination from chemical spills.

**Probability of Future Occurrence of the Hazard:**

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years.210 If we consider historical occurrence as one data set for estimating future events, the average rate of occurrence over the past 150 years is 1 tsunami every 1.9 years statewide. Currently, no analysis is available which differentiates this statewide probability specifically for the impacted assets.

That said, the rate of future occurrence may change and may be able to make target estimates for specific locations in the future; the California State Tsunami Program is trying to refine the accuracy of the data. In doing so, the State Tsunami Program is completing a set of Probabilistic Tsunami Hazard Analysis (PTHA) maps representing risk levels from 100-year to 3000-year average return periods. Analysis using these probabilistically based products will allow for a more common platform for comparison to other seismic and flood probabilistic analyses. 211

**Vulnerability to the Hazard:**

Regarding the vulnerabilities for the campus, the aquaculture building, the Norte Facility, and the Small Boat and Diving Operations buildings in Moss Landing are all vulnerable to the hazard as they fall within the tsunami inundation area. Tsunami “maximum run-up” projections were modeled by the University of Southern California and distributed by the California Office of Emergency Services for the purposes of identifying tsunami hazards. The tsunami model was the result of a combination of inundation modeling and onsite surveys and determined the maximum projected inundation levels from tsunamis. Given

211 2018 State of California Hazard Mitigation Plan
that inundation modeling changes over time and is not able to predict real world outcomes with 100% accuracy, it is conceivable that an actual worst case tsunami event could impact the campus.

Given that the entire campus is not impacted, the vulnerability is specific to the operations of the three facilities and should not have a significant impact on campus operations.

**Vulnerability of Populations**

The populations most vulnerable to the tsunami hazard are the elderly, disabled and very young who reside near beaches, low-lying coastal areas, tidal flats and river deltas that empty into ocean going waters. In the event of a local tsunami generated near the coast, little warning time would exist, so more of the population would be vulnerable. While direct impacts to campus staff and students are not projected, the city’s evacuation capability could be exceeded by a worst-case event.

**Estimate of Potential Losses**

Estimates of potential losses specific to CSU campuses have not been conducted yet. Improvements have been made in the ability to estimate losses from tsunami impacts which can be brought to bear on loss estimation for CSU campuses in the future.

**Vulnerability Assessment Conclusions:**

According to the 2018 State of California Hazard Mitigation Plan, community exposure to tsunamis in California varies considerably—some communities may experience great losses that reflect only a small part of their community and others may experience relatively small losses that devastate them. Among the 94 incorporated communities and 83 unincorporated areas of the 20 coastal counties, the communities of Alameda, Oakland, *Long Beach*, Los Angeles, Huntington Beach, and San Diego have the highest number of people and businesses in the tsunami inundation zone.\(^\text{212}\)

For improving assessments of vulnerability, FEMA has developed a new tsunami loss estimation module for HAZUS using existing numerical model results for tsunami inundation, flow depth, velocity, and force. This HAZUS module allows new capability for estimation of economic losses, and site-specific analysis of content losses, casualties, infrastructure damage, and evacuation time. The module calibrates losses based on safe zones and community preparedness levels. Such technological improvements in assessment capability can be utilized for tsunami hazard analysis and planning purposes for the campus assets.

Along with new probability-based tsunami maps, the HAZUS module will improve the ability to compare tsunami impacts to those of other hazards. Moreover, the probability mapping will be used for numerous applications including identifying potential tsunami hazard “zones of required investigation” under the Seismic Hazards Mapping Act and will assist state and local agencies in making land use planning decisions. They will also help regional and state planners understand the flood potential from tsunamis representing different risk levels.²¹³

Identified Data Limitations:

As identified in the vulnerability conclusions (above), with regard to the current planning effort, the primary data limitations for assessing the tsunami hazard for CSU campuses mostly pertain to a complete set of valuations for the assets of the campus assets lying within the tsunami inundation zone. In addition, the CSU system-wide effort would benefit from FEMA’s new probability mapping techniques and tsunami loss estimation module to the footprint of those campuses proximate to the inundation zone to ensure that the current “not at risk of direct impact” to staff, students and physical assets still holds true. That said, CSU leadership and planning teams intends to pursue such data in the future.

²¹³ 2018 State of California Hazard Mitigation Plan
22.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU San Jose campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
Table 22-39: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning?</td>

<td>N/A</td>
</tr>
</tbody>
</table>

Note: San Jose State was early interview, so interview process and question structure were not fully defined.

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees,
the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Have a large group of international students; noted that they should have a copy of the separate plan and policies prepared by the International Dept.
- LGBTQI are not treated any differently; all [campus population] groups are treated the same way.
- If had an event, undocumented students would not be arrested.
Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\(^{214}\) Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\(^{215}\) Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the

---

22-169
major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.216

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitoes that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 217

**Flood**

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse

impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. 218

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural health and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, anger, sadness and grief. 219

Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

**Hazardous Materials**

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease.\(^220\) Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.\(^221\)

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

\(^{220}\) [https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/](https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/)

Volcanoes

There has been limited analysis on the full social and economic impacts of volcanic eruptions, but known impacts show extensive disruption to livelihoods, through evacuation or destruction of land and resources. Typically, indirect fatalities happen across even longer time scales than primary fatalities, and so social processes associated with wellbeing and secure livelihoods are even more likely to be a driver for risky behavior.\(^{222}\) Having access to (or neglecting) warning systems impacts one’s decision to leave. A volcanic eruption can impact health. Ashfall from volcanoes contain carbon dioxide and fluorine, gases that can be toxic to humans, and can collect in volcanic ash. The resulting ashfall can lead to crop failure, animal death and deformity (impacting financial security for those dependent on farming), and human illness. Ash's abrasive particles can scratch the surface of the skin and eyes, causing discomfort and inflammation. Further effects are the deterioration of water quality, fewer periods of rain, crop damages, and the destruction of vegetation. During volcanic eruptions and their immediate aftermath, increased respiratory system morbidity has been observed as well as mortality among those affected by volcanic eruptions. Health hazards can range from minor to life threatening. Exposure to acid gases such as sulfur dioxide, hydrogen sulfide, and hydrogen chloride can damage eyes and mucous membranes along with the respiratory system and, under extreme conditions, can lead to death.\(^{223}\)

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.

- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and once deposited, poison drinking water, agricultural crops, and grazing land.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Moreover, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.

---

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.\textsuperscript{228}

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

23.1 University Profile

University History

Cal Poly San Luis Obispo held its first classes on October 1, 1903, two years after Governor Gage signs a bill on March 8, 1901 establishing the California Polytechnic School. By 1947, the California Polytechnic School is renamed the California State Polytechnic College and begins offering graduate programs in education.

Cal Poly is designated as an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The president receives advisory support from The President’s Council of Advisors, a carefully selected group of professionals. The Council of Advisors enhances the relationship between the university and its constituent communities, including business, industry, agriculture, the professions and the arts. The President’s Council of Advisors is a group of individuals who represent leaders of professions, business, industry and communities. The Council convenes regularly to provide advice, advocacy, access, leverage and resources for the university.

University Mission

“Cal Poly fosters teaching, scholarship, and service in a learn-by-doing environment in which students, staff, and faculty are partners in discovery. As a polytechnic university, Cal Poly promotes the application of theory to practice. As a comprehensive institution, Cal Poly provides a balanced education in the arts, sciences, and technology, while encouraging cross-disciplinary and co-curricular experiences. As an academic community, Cal Poly values free inquiry, cultural and intellectual diversity, mutual respect, civic engagement, and social and environmental responsibility.”

University Location

Cal Poly San Luis Obispo is located in San Luis Obispo on California’s Central Coast, about halfway between Los Angeles and San Francisco. Cal Poly students benefit from hands-on research in agriculture, winemaking and distinctive coastal ecosystems, as well
University Population

Cal Poly San Luis Obispo’s student body exceed 21,000 students, both undergrad and graduate.

23.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.
23.3 Hazard Identification and Risk Assessment

Overview of Cal Poly San Luis Obispo History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 23-1 (following).

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely**- 76%-100% that the hazard would occur annually.
- **Likely**- 50%-75% that the hazard would occur annually.
- **Possible**- 11%-49% that the hazard would occur each annually.
- **Unlikely**- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent.¹ They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions.² The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.³

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)⁴

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 23-2 below.)

**Descriptions of Identified Communicable Disease Hazards at Cal Poly San Luis Obispo**

Cal Poly San Luis Obispo (Cal Poly SLO) has identified three (3) communicable disease hazards that have had the greatest impact on campus – COVID-19, Meningitis, and Norovirus. The following are brief descriptions of the communicable disease hazards at Cal Poly SLO.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.

**Meningitis**

Meningitis is an inflammation of the fluid and membranes (meninges) surrounding the brain and spinal cord. The swelling from meningitis typically triggers signs and symptoms such as headache, fever and a stiff neck. Early meningitis symptoms may mimic the flu (influenza). Symptoms may develop over several hours or over a few days.

Most cases of meningitis in the United States are caused by a viral infection, but bacterial, parasitic and fungal infections are other causes. Some cases of meningitis improve without treatment in a few weeks. Others can be life-threatening and require emergency antibiotic treatment. Bacterial meningitis is particularly serious and can be fatal within days without prompt antibiotic treatment. Delayed treatment also increases the risk of permanent brain damage or death.

**Norovirus**

Norovirus is a highly contagious virus commonly spread through food or water that is contaminated by fecal material during food preparation or by contaminated surfaces.

---

Specifically, this virus can be transmitted through: consuming contaminated food, drinking contaminated water, and touching one’s hand to one’s mouth after the hand has been in contact with a contaminated surface or object. Norovirus can also be transmitted through close contact with an infected person.

Norovirus infections occur most frequently in closed and crowded environments such as hospitals, nursing homes, child care centers, schools and cruise ships. Noroviruses are difficult to kill off because they can withstand hot and cold temperatures and most disinfectants.

Symptoms such as diarrhea, stomach pain and vomiting typically begin 12 to 48 hours after exposure, and usually last one to three days. Most people recover from norovirus completely without treatment. However, for some people — especially infants, older adults and people with underlying disease — vomiting and diarrhea can be severely dehydrating and require medical attention. 7

Location of the Hazard

Communicable diseases have the potential to affect the entire Cal Poly San Luis Obispo (Cal Poly SLO) planning area equally. As a result, the communicable disease hazard can be found at the Cal Poly SLO campus located in San Luis Obispo, CA (San Luis Obispo County), as well as at the Cal-Poly-SLO-owned 3000-foot research pier in nearby Avila Beach (San Luis Obispo County) that is used for field work, research cruises, and scientific diving programs. Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) the Cal Poly SLO main campus and affiliated facilities are at risk of exposure to the communicable disease hazard.

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. Table 23-4 shows the number of students that were living in CSU-campus-owned housing in Fall, 2019, prior to the COVID-19 pandemic. For Cal Poly SLO, approximately 37% of its 21,242 enrolled students (or 7,860 students) reside in student housing. 8,9

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 23-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

Figure 23-1: Biosafety Levels (BSLs)

The Extent of Cal Poly San Luis Obispo (SLO) Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Meningitis and Norovirus at Cal Poly SLO. Meningitis would be classified at the BSL-2 containment level, and Norovirus would also be classified at the BSL-2 containment level. 11

The Extent of Cal Poly San Luis Obispo (SLO) COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3. 12

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 1,626 cases of COVID-19 at Cal Poly SLO. CSU-campus-specific COVID-19 case data for Cal Poly SLO can be found in the History of the Hazard section below.

Most communicable disease data are maintained by at the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 23-5 and 23-6 show campus-level and County-level COVID-19 Case data for Cal Poly San Luis Obispo (Cal Poly SLO). These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

(Nete: On-campus and off-campus case data reflect only tests administered through Campus Health and Wellbeing or through the university’s ongoing testing program. Total confirmed case data include additional campus resident students who have tested)

Positive via off-campus testing sites. Positive tests for employees or off-campus resident students obtained off campus are not reported to Cal Poly SLO unless they require contact investigation or isolation/quarantine actions on campus. Instead, these off-campus positive tests are reflected in countywide and community-specific statistics (for their community of residence).

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the Cal Poly SLO campus. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of Cal Poly SLO students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including Cal Poly SLO) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.). 15

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 23-6: WHO Risk Group Categorization16

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 23-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

### Probability of Future Occurrence of the Hazard

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency. Table 23-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

| RG 3 | Anthrax  
|      | West Nile Virus  
|      | SARS Virus (Including COVID-19)  
|      | Tuberculosis  
|      | Typhus  
|      | Yellow Fever  
|      | Hantaviruses  
|      | Avian Flu  

| RG 4 | H5N1 (Bird Flu)  
|      | Dengue  
|      | Hemorrhagic Fever  
|      | Marburg Virus  
|      | Ebola Virus  
|      | Smallpox  
|      | Lassa Fever  
|      | Crimean-Congo Hemorrhagic Fever  
|      | Other Hemorrhagic Diseases  

23-16
Table 23-8: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

*Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.*

</table>
Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at Cal Poly SLO campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. As of Fall 2019, CSU – San Luis Obispo had 21,242 students and additional faculty and staff. Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree in the current COVID-19 pandemic on the Cal Poly SLO campus.

Estimate of Potential Losses

**COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities**

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including Cal Poly SLO) are at risk of developing an extreme incidence of

---

18 The California State University. *Enrollment*. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

COVID-19 and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 23-2 below for the economic impact to the campus). Several CSU campuses saw refund losses surpass $10 million. (See Figure 23-2.)

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity. At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services and could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 23-12 below for the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system, including to Cal Poly SLO. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

Dam and Levee Failure

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.
A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from over toppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

San Luis Obispo County is home to a limited number of flood control facilities and levee systems. The dam facilities are mostly found along the various mountains and hills throughout the county. Levees have been constructed along the Santa Maria River channel and the Arroyo Grande Creek. The Cal Poly San Luis Obispo campus is in proximity to one small dam that is uphill to the north of the campus. The campus is not in proximity to rivers or flood control channels lined with levees.

The sole dam facility near the Cal Poly San Luis Obispo campus is the Chorro Creek Dam. The Chorro Reservoir is a small reservoir with the potential holding capacity of 90-acre feet of water when full. The San Luis Obispo campus lies outside of the dam inundation zones for the Chorro Creek facility. The Chorro Creek inundation zone extends along the Chorro Creek west of the campus. All of the above inundation zones affect transportation routes and other critical infrastructure west of San Luis Obispo potentially affecting access and support services to the campus.

Figure 23-4: Chorro Creek Dam Breach Inundation Map

28 California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- High hazard potential dams may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- Significant hazard potential dams are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
Low hazard potential dams are not expected to result in loss of like, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

Table 23-12: Dams in Proximity to Cal Poly San Luis Obispo

<th>Dam</th>
<th>Storage</th>
<th>Hazard Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chorro Creek</td>
<td>Chorro Creek</td>
<td>90af</td>
<td>High Hazard</td>
</tr>
</tbody>
</table>

The Cal Poly San Luis Obispo campus lies outside of the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the Cal Poly San Luis Obispo campus is expected to remain out of the inundation area. The location of the campus is 2 ½ miles to the southeast from the Chorro Creek Reservoir. However, the dam inundation zone for the Chorro Creek Reservoir turns to the west and away from the campus. The campus is 2 ½ miles from the boundary of the dam inundation zone. Additionally, State Route 1 lies within the dam inundation zones that could compromise access, evacuation, and supply routes to the west towards Morro Bay. The inundation areas have the potential to isolate areas the campus community reside or work to the west of San Luis Obispo. Based on the above factors, the planning committee ranks the extent of the hazard for the campus as **Low**.

**Extent: Levee Failure**

There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. As such, the planning committee ranks the extent of the hazard for the campus as **Low**.

**History of the Hazard**

There are no records or dam or levee failures in areas that present a threat to the Cal Poly San Luis Obispo campus. San Luis Obispo County has no record of dam failures.

30 San Luis Obispo County Local Hazard Mitigation Plan, October 2019
Potential Impacts of the Hazard

Dam Failure Impacts - While the campus is not within a dam inundation zone, transportation routes, critical infrastructure, and campus community members may reside within inundation zones. Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

Probability of Future Occurrence of the Hazard

San Luis Obispo County remains at risk from dam failure, especially from 13 dams around the county. All but the Chorro Creek Dam are not in proximity to the Cal Poly San Luis Obispo campus and are separated by significant geographic barriers. The location of the campus is 2 ½ miles to the southeast from the Chorro Creek Reservoir. However, the dam inundation zone for the Chorro Creek Reservoir turns to the west and away from the campus. The campus is 2 ½ miles from the boundary of the dam inundation zone. There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on historical experience and occurrences, the likelihood of this hazard is low.

The probability of future occurrence for both dam and levee failures is Unlikely.

Vulnerability to the Hazard

Given high priority monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. In addition, the campus does not lie within an inundation zone. As such, the campus is not considered to be truly vulnerable on a daily basis. However, in the unlikely event of a catastrophic failure, the effects of flooding from compromised dams and levees on campus would most likely be limited to indirect or secondary effects in terms of disruption to regional transportation networks and services, and the amount of time to respond to the needs of the campus community prior to inundation will be limited.

Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational
intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations in the event of a low probability, catastrophic event.

The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in the vulnerability of numerous displaced individuals and households. The lack of flood insurance will cause additional extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the Cal Poly San Luis Obispo campus will vary depending on the degree of breach or structural failure and when the failure were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs are $660,197,687. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at Cal Poly San Luis Obispo.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the Cal Poly San Luis Obispo campus, the potential for hazards related to the region’s
levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences would be catastrophic to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.

**Drought**

**Description of the Hazard**

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:
- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.

- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for Cal Poly San Luis Obispo versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified throughout San Luis Obispo County (where the campus is located). Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to the campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020,
drought conditions existed continuously in the state, with 80-100% of the state impacted for 12 of the last 20 years. 31

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout the planning area and across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire planning equally, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction.

In addition, land subsidence has occurred statewide and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines over the long term.

Although the campus planning team identifies the current extent of the hazard as Low (qualitatively) which corresponds to D0 – D1 on the Extent scale (below), San Luis Obispo County has experienced more severe drought conditions over the past 20 years, including 3 years of D4 levels during the statewide drought from 2012-2017. As such, the campus planning team recognizes that while historic impacts shaping the extent of drought on campus have been minimal, the potential impacts are tied to a fragile local water supply with no restrictions in place, and tied to trends across larger geographic areas, and, therefore, the committee recognizes that the extent of drought on campus has the potential to increase in the future.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

</tbody>
</table>

### History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous, according to the US Drought Monitor, Time Series data, San Luis Obispo County (which includes the Cal Poly San Luis Obispo footprint) has experienced five or more periods of drought covering 12 years from 2000-2021.

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.
According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 34

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.
Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the Cal Poly San Luis Obispo campus planning area:

**2012 – 2017** – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2014-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.

**Potential Impacts of the Hazard**

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the Cal Poly San Luis Obispo campus planning area is a reduction in water availability for the municipal

area tied to each campus. The campus planning committee reports that the municipal supply is fragile with just one water main connecting the campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of Cal Poly San Luis Obispo to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of agricultural research crops and field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. 37 However, the wildfire hazard is analyzed separately in this plan.

In reviewing drought for San Luis Obispo County, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to Cal Poly San Luis Obispo, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campus. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data are currently available for tree mortality on campus, however, the CSU Planning Team will try to acquire data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the

range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area. 38

At present, drought related damage to campus buildings and infrastructure at Cal Poly San Luis Obispo has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for Cal Poly San Luis Obispo is ultimately tied to a fragile local water supply and to broader inter-dependent, and more intensive modes of water use and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced. Although no restrictions are currently in place locally, if out in place, impacts tied to reduced water availability can occur for all usage contexts at Cal Poly San Luis Obispo. A reduction of electric power generation and water quality deterioration are also potential impact

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that Cal Poly San Luis Obispo lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the Cal Poly San Luis Obispo campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the Cal Poly San Luis Obispo planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. 40

---

forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

Vulnerability of Populations

Drought vulnerabilities on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the Cal Poly San Luis Obispo campus.

Property Vulnerability

Drought vulnerabilities for property statewide include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the Cal Poly San Luis Obispo campus over the long term, given the fragile and expensive local water supply.

Natural Environment Vulnerability

Drought vulnerabilities for the natural environment on campus are primarily campus landscaping and other flora. Statewide, widespread vulnerabilities exist throughout public and private lands, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds. The core issue shaping drought vulnerabilities throughout California and on campus is water supply and demand. The campus planning committee indicates that water supply is a low protocol issue locally, with no restrictions in place, although it is quite costly for the

campus, with supply limited to one water main. These issues are tied to broader factors including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for Cal Poly San Luis Obispo’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence over the long term.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of San Luis Obispo and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSPU Planning Committee understands that the high degree of vulnerability posed by drought centers on the low priority for restricting local usage and the need to improve campus access beyond one water main while reducing cost. These issues will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campus by accessing the best available data and resources on climate change and its relationship to

**Identified Data Limitations**

Data are limited concerning campus-related agricultural assets as well as data on campus tree mortality.
**Earthquake**

**Description of the Hazard**

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.
**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. Cal Poly San Luis Obispo is located on the California Central Coast in central San Luis Obispo County. In general, fault systems surround and traverse through San Luis Obispo County including the area of Cal Poly San Luis Obispo. Throughout the county there are areas where ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 35 miles northeast of the Cal Poly San Luis Obispo campus. In addition to the San Andreas Fault, San Luis Obispo County is home to or near additional fault systems with the potential to generate strong ground shaking. The Oceanic-West Huasna Fault follows the mountains 2 miles north of the campus. The Los Osos Fault is another southeast to northwest fault 3 ½ miles south of the campus. The Hosgri Fault parallels the coastline extending from Point Arguello to Big Sur approximately 16 miles west of the campus. The Rinconada Fault traverses south to north through Santa Margarita and Paso Robles extending 7 miles northeast of the Cal San Luis Obispo campus. There are numerous additional faults in the area on all sides of the campus.
The Cal Poly San Luis Obispo campus reside within areas designated to be liquefaction zones. All campus facilities are located within the moderate liquefaction zone or areas where liquefaction zones overlap with areas prone to landslides. Additionally, substantial areas of the community surrounding the campus reside within the liquefaction zones including access routes into and out of the campus. This includes US Highway 101, State Route 1, and the Union Pacific Railroad. The liquefaction zone generally follows the path of creeks and valley floors.

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity, and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and
evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

Table 23-17: Modified Mercalli Intensity Scale

<table>

</tbody>
</table>
The impacts of a major earthquake would be felt beyond the campus and have long reaching effects. The risk of casualties and damages would likely extend to the homes and workplaces of members of the campus community including students, staff, and faculty. Based on the location of the campus surrounded by fault lines, the southwest portion of the campus being in a liquefaction zone, the history of occurrences (some with extensive damages) in the area, and the potential for future impacts, the campus planning committee ranks the extent of the hazard as Moderate to High.

History of the Hazard

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Likewise, San Luis Obispo County also has a long history of earthquake activity. The entire area of the Central Coast area is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The above earthquakes had federal disaster declarations declared:

- San Simeon (DR-1505-CA)
- Coalinga (DR-682-CA)

The December 22, 2003 San Simeon Earthquake became one of the most well-known earthquakes in California history to generate changes in building codes. The earthquake caused extensive damage to buildings, bridges, water systems, and critical facilities. Damage was experienced heavily in unreinforced masonry buildings and other structures. Two people were killed and many more injured. The San Francisco Earthquake was found primarily to affect Paso Robles and Templeton but the shaking was felt from San Francisco to Los Angeles.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can

---

additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Los Angeles area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near San Luis Obispo could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near San Luis Obispo could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Central Coast region limiting immediate assistance that the campus may normally expect.

Local impacts to the Cal Poly San Luis Obispo campus caused by an earthquake could include:

- Injuries and damage related casualties
- Ground rupture
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway and roadway system
- Landslides blocking primary access routes including US 101 and CA SR 1
- Damage to rail lines transiting through San Luis Obispo
- Structural damage to bridges over waterways and flood control channels
- Damage to power grid and widespread power outages
- Disruption in water services
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to flood control facilities
- Structural damage to campus academic and support buildings
- Damage or loss of academic research, documents, electronic storage, art, and literature.
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Gaps in service delivery to vulnerable populations
- Considerable stress and fear among community
- Spontaneous creation of tent cities or outdoor camping on personal property
- Closure or reduction of service to campus operations
- Reduction of campus revenue

**Probability of Future Occurrence of the Hazard**

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the San Luis Obispo County fault systems surrounding San Luis Obispo is included in the following table.

The San Luis Obispo County Local Hazard Mitigation Plan estimates the probability of a major earthquake to occur is likely. The Plan identifies those earthquakes ranging from magnitude 7.0 to 7.9 occur 1 out of every 10 years and earthquakes ranging from magnitude 6.0 to 6.9 occur once every two or three years on average.

Based on the earthquake shaking potential in the San Luis Obispo area, the proximity to the above listed fault systems, and liquefaction potential exists on the southwest corner of the campus, the probability of seismic ground shaking generating damage is considered **Possible**.

**Vulnerability to the Hazard**

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of Cal Poly San Luis Obispo places the campus in a suburban community near residential, commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to San Luis Obispo generally surround the city and some cross into the city including near the Cal Poly San Luis Obispo. The campus

45 San Luis Obispo County Local Hazard Mitigation Plan, October 2019

46 Southern California Earthquake Center, Earthquake Information, https://scedc.caltech.edu/earthquake/faults.html#

resides in a region that is exposed to fault systems on all sides. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the Cal Poly San Luis Obispo campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the area. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. This may be heightened in the southwestern portions of the campus as this area has been identified as being within a liquefaction zone. As the Cal Poly San Luis Obispo campus is downstream from a dam facility, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

San Luis Obispo is served by only three primary surface transportation routes. The primary route being US Highway 101 providing roadway access to the Los Angeles area.
200 miles to the south and to the San Francisco Bay Area 200 miles to the north. California State Highway 1 also extends to the north however this is a winding route along seaside cliffs subject to landslides. A major earthquake has the potential for rendering these critical lifelines and supply routes inoperable and forcing the campus community to be self-reliant for a period of time.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $660,197,687.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater San Luis Obispo County and the Cal Poly San Luis Obispo campus. Each of the earthquake generated effects will vary
widely based on the intensity of the earthquake, location of the epicenter, proximity to
people and development, time of day and year, the soil composition under the impacted
structures, building construction, among others. In any case, the potential for a major
earthquake exists affecting the campus and causing extensive challenges to the Cal Poly
San Luis Obispo campus and community.

In the event that a major earthquake was to strike along the many fault systems
surrounding San Luis Obispo, the effects could be significant to the campus community
and campus operations. The widespread impacts generated by a major earthquake would
extend the effects of casualties, damages, and other impacts to the broader San Luis
Obispo County region creating large-scale regionwide needs for critical assistance and a
heavy demand on limited emergency resources. The threat and impacts presented to the
campus will be shared with the campus community from their homes and places of work.
The campus will likely be required to address critical needs independently during early
phases of the disaster.

The campus population are additionally vulnerable to the effects of major ground shaking
that are far reaching. The psychological and social impacts a major earthquake will give
rise to will potentially harm individuals and cause tremendous fear. The willingness to
return indoors may be hampered especially as after-shocks continue. These effects are
magnified for populations having specific vulnerabilities or access limitations.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of a
complete inventory of building construction types to include status of earthquake
retrofitting. HAZUS generated analysis is focused on the broader community level versus
fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Erosion**

**Description of the Hazard**

The US Geological Survey (USGS) defines erosion as “the process whereby materials of
the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from
one place to another” 48 Erosion may occur in areas of streams and rivers, along bluffs,
around immovable objects (such as buildings or bridge abutments), or as a cascading
result of other natural hazards, such as earthquakes or wildfires. When erosion occurs
along bodies of water, the removal of material causes the shore to move further
landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable.

Location of the Hazard

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. As such, for the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the Cal Poly San Luis Obispo campus with erosion-prone characteristics. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area.

Extent of the Hazard

While there is no published scale of severity or extent for this geologic hazard on the Cal Poly San Luis Obispo campus, erosion is likely to occur if conditions are favorable. That said, no such areas have been identified. As such, the planning committee ranks the extent of the hazard as Low.

History of the Hazard

There is no record of erosion incidents on the Cal Poly San Luis Obispo campus.

Potential Impacts of the Hazard

Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

In agricultural areas, the erosion of soil degrades the quality of the soil, which can lead to reduced crop yields. At the Cal Poly Farm, soil erosion can create significant concerns for agriculture and research. Eroded test plots can negatively impact experiments and tests, resulting in a loss of knowledge and data.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, the probability of future occurrence is

high. That said, with regard to the campus, given the lack of historical events or existing conditions favorable to erosion, the probability of future occurrence is **Low**. However, conditions could emerge in the future which increase the probability, precipitated by climate change, changes in land-use or other factors.

**Vulnerability to the Hazard**

Topography, soil structure, land use, and precipitation are all factors of erosion. Cal Poly San Luis Obispo infrastructure, buildings, and agriculture located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. CSU leadership would consider performing an analysis to identify such at-risk buildings, infrastructure, slopes and soil types in the future.

In the wider San Luis Obispo community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

**Vulnerability Assessment Conclusions**

While the ability to predict future erosion on the Cal Poly San Luis Obispo campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.50

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.51 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.52

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.53 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.54

**Location of the Hazard**

Extreme heat events are a non-spatial hazard and may occur at the Cal Poly San Luis Obispo campus.

**Extent of the Hazard**

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately

52 Ibid.

from the low-70s to mid-70s in San Luis Obispo County. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at the San Luis Obispo Polytech Station was 112° F on September 14, 1971. Given the historical occurrence of only 3 extreme heat events since 1950, and average maximum temperatures in the 70’s, the planning committee ranks the extent of the hazard as Low.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 23-10 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.

Table 23-20: Health Risks Associated with Heat Index

</tr>
</tbody>
</table>

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been three excessive heat events in San Luis Obispo County since 1950.

**July 22, 2006:** An extended period of excessive heat affected San Luis Obispo, Santa Barbara, Ventura, and Los Angeles Counties. Heat index values ranged from 100° to 119° F.

**September 3, 2007:** A combination of high temperatures and high humidity produced an extreme heat event across the County and throughout Southern California. Heat index values ranged from 105° to 112° F. There were eight deaths attributable to this excessive heat event.

**June 20, 2008:** Afternoon high temperatures during this extreme heat event climbed as high as 114° F. The heat resulted in several power outages due to excessive electrical use.

Potential Impacts of the Hazard

Cal Poly San Luis Obispo may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which

can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

There have been no extreme heat events in San Luis Obispo County in over a decade and only 3 events in total. Therefore, using the scale provided, it is Unlikely that the hazard will occur annually.

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.57 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Cal Poly’s Office of Environmental Health and Safety has published nearly two dozen Codes of Safe Practice for the campus, which are designed to follow CAL/OSHA regulations and prevent injury and illness. One such code describes precautions and rules that should be followed to prevent heat illness when there have been more than 48 hours of high heat (defined as 90° F or higher) and high humidity (defined as 80% or higher).58 The code includes practices that should be followed even at lower levels of heat and humidity for special circumstances (e.g., workers wearing heavy or protective gear or clothing). The rules include suggestions for providing water, shade, and rest breaks, as well as descriptions for concerning symptoms for heat cramps, heat exhaustion, and heat stroke.

Overall, while Cal Poly does not include extreme or excessive heat as part of its Emergency Operations Plan due to the minimal extent and probability of the hazard, the

campus’s Office of Environmental Health and Policy is aware of the risks and vulnerabilities of this hazard, particularly when it comes to the protection of staff and campus workers.

**Estimate of Potential Losses**

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

**Vulnerability Assessment Conclusions**

While the ability to predict future heat events at the Cal Poly campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), South-Central California has warmed about 2 – 3 degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.59

That said, due to the minimal extent and probability of the hazard, campus leadership is aware of the risks and vulnerabilities of this hazard, particularly when it comes to the protection of staff and campus workers.

**Identified Data Limitations**

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

**Flood**

**Description of the Hazard**

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California

Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Floods can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Floods can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur.
from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric Rivers**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
San Luis Obispo is located in San Luis Obispo County in the center of the Central Coast. San Luis Obispo County can experience flooding from overflowing streams and heavy precipitation events in low lying areas such as central San Luis Obispo. These areas can experience shallow flooding impacting roadways and other areas where drainage is inadequate. San Luis Obispo is located in a valley that gradually rises to the north and east toward the Santa Lucia Range. Adjacent to the Cal Poly San Luis Obispo campus are both residential neighborhoods and commercial land uses.

60 National Oceanic and Atmospheric Administration, “What are atmospheric rivers?”, https://www.noaa.gov/stories/what-are-atmospheric-rivers
The Cal Poly San Luis Obispo campus is located at the base of mountains that provide drainage through the campus. The campus is split by the Brizzolara Creek and is near Stenner Creek, Chorro Creek, and the San Luis Obispo Creek. Each of these waterways drain the upstream watersheds that capture runoff from the hills and mountains that line the San Luis Obispo Valley. These waterways are normally dry except during periods of precipitation when the potential for large volumes of water is possible. The majority of the campus is designated as Zone X (Area of Minimal Flood Hazard). However, bordering on the west side of the campus is a Zone A (Area Inundated by 1% Annual Chance for Flooding) that follows the Stenner Creek and a Zone A (Area Inundated by 1% Annual Chance for Flooding) that buffers the Brizzolara Creek that transits through the northern half of the campus.
Extent of the Hazard

The Cal Poly San Luis Obispo campus is located in a designated Zone X: Area of Minimal Flood Hazard except for the Brizzolara Creek flood control channel which is designated as Zone AE: 1% Annual Chance Flood Hazard. The access routes into and out of the campus servicing locations to the west are found in areas primarily designated as Zone X: Area of Minimal Flood Hazard, access routes that cross streams are primarily located in Zone AE: 1% Annual Chance Flood Hazard at the point of the crossing. Based on the campus being located primarily in Zone X, but also containing portions located in Zone AE along creeks, the planning committee ranks the extent of the hazard as **Low to Moderate**.

---

61 Federal Emergency Management Agency, FEMA Flood Map Service Center, [https://msc.fema.gov/portal/search#searchresultsanchor](https://msc.fema.gov/portal/search#searchresultsanchor)

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 23-21: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised maps in place on Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, base flood elevations derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
<tr>
<td>Zone AH</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.</td>
</tr>
<tr>
<td>Zone AO</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.</td>
</tr>
<tr>
<td>Zone X (shaded)</td>
<td>0.2%</td>
<td>Represents areas between the limits of the 1% annual chance of flooding and 0.2% chance of flooding.</td>
</tr>
</tbody>
</table>
Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than 1 foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than 1 square mile, or areas protected from the 1% annual chance flood by levees.

No BFE or depths are shown within this zone.

History of the Hazard

Flooding in San Luis Obispo and the broader Central Coast region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following table (23-24) provides insight into information of past flooding events that are significant to the Cal Poly San Luis Obispo campus. Flood events on campus are reported by campus staff to primarily be occasional localized flooding or ponding in certain parts of campus. No evacuation or campus closure flood events have been reported.

63 San Luis Obispo County Local Hazard Mitigation Plan, October 2019
Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source.

Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flood inundation of the Cal Poly Water resources Facility and domestic water capabilities
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Flood exposure to on campus livestock
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Inability for campus operations to resume
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

San Luis Obispo County is determined to have considerable portions of the county to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common along the Central Coast with winter storms that are saturated with subtropical moisture. The area surrounding the Cal Poly San Luis Obispo campus does not generally promote conditions for flood waters to accumulate with the exception along creek channels. The majority of the campus is designated as Zone X (Area of Minimal Flood Hazard). However, bordering on the west side of the campus is a Zone A (Area Inundated by 1% Annual Chance for Flooding) that follows the Stenner Creek and a Zone A (Area Inundated by 1% Annual Chance for Flooding) that buffers the Brizzolara Creek that transits through the northern half of the campus. Much of downtown San Luis Obispo is classified as Zone AO (Area Inundated by 1% Annual Chance for Flooding with Water Depths of 1-3 Feet). Access in and out of the campus may become compromised in flooding events off campus. There are specific buildings and areas of the campus that have a greater risk for isolated flooding. However, the area is subject to isolated urban or street flood events providing a demonstration of potential flood activity.

The probability of future occurrence for flooding on the campus is Possible.

Vulnerability to the Hazard

The Cal Poly San Luis Obispo campus is subject to the effects of localized flooding resulting primarily from excessive precipitation and isolated strong storms. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of San Luis Obispo due to overflow or damage to flood control systems. The channels and extending irrigation channels that surround the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the Cal Poly San Luis Obispo campus will vary depending on when the flood was to occur. The risk to the campus population will be lessened during
periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community may become trapped on campus depending on the level of flooding occurring on surface streets. However, in rare region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

Cal Poly San Luis Obispo is in proximity to a variety of agricultural, industrial, and commercial facilities in the surrounding communities. When these facilities are inundated with flood water, the potential for chemical release exists presenting possible exposures to individuals from the campus community. These facilities additionally line many of the primary access routes in and out of the campus.

During low probability, severe flood events, some campus buildings and infrastructure might be vulnerable to large-scale flooding reaching the university. Campus utilities and communication capabilities might be impacted by flood waters rendering them disabled. A rare flood event covering a large portion of the city would likely affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. Flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings in areas of localized or isolated flooding.

The limited transportation routes into and out of the San Luis Obispo area creates a potential scenario in which the campus and surrounding communities may become isolated in widespread flooding situations. US Highway 101 provides the primary ground access routes to areas in California with additional services and capabilities. Flooding of this critical lifeline will impede the ability to receive supplies, equipment, and additional resources while also limiting or removing the ability to evacuate the campus community from the area.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters
will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $660,197,687. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is mostly located in an area of minimal flooding, the primary vulnerabilities to flood on campus are people and assets exposed to mostly localized flooding from overflow of campus creeks or isolated or large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. The proximity to the Chorro and Stenner Creek presents an additional minimal or limited flood hazard for the campus.

The potential for rare but severe flooding generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular populations among the
campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

---

**Hazardous Materials**

**Description of the Hazard**

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident**: A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident**: A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

---

Pipeline Incident: A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

Natural-Technological Incidents (Natechs): During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

Location of the Hazard

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. The planning committee indicates that biological materials are located in the science lab on campus. At larger scales (beyond the campus planning area) hazardous materials are located throughout the city and county of

San Luis Obispo and reflect different types, configurations and scales dispersed across these geographic areas.

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard. However, for the CPSU – San Luis Obispo planning committee, although no hazmat events have taken place on campus, hazardous materials include biological material located in the science building and both railroad and gas pipeline run extremely close to the campus. Based on these factors along with the types and levels of hazardous materials in the larger community, it is prudent to rank the extent of the hazard for the CPSU – San Luis Obispo campus as Moderate, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

For more details on specific hazmat events, please refer to the local, county and/or multi-jurisdictional hazard mitigation plans where CSU campuses are located at: https://www.caloes.ca.gov/cal-oes-divisions/hazard-mitigation/hazard-mitigation-planning/local-hazard-mitigation-program

No hazmat incidents have taken place on the CPSU – San Luis Obispo campus.

**Potential Impacts of the Hazard**

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CPSU – San Luis Obispo campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose
severe risks to public health. Health effects from exposure to these metals included short-
term symptoms such as irritation to the eyes, nose, throat, and lungs.71

Potential Impact of the Hazard (Natechs) Natural disasters, including earthquake, flood,
and fire also pose risks to public health and the environment. For example, following the
Northridge Earthquake, California State University (CSU) Northridge laboratories and
chemical storage rooms experienced multiple chemical spills. Such incidents, triggered
by a natural disaster, pose a significant risk to students, faculty, staff, and first
responders. At a minimum, all CSU campuses with a science lab (including CPSU – San
Luis Obispo) is at risk of potential impact from a natural-technological (combined impact)
event.

In a severe flood event, floodwaters are often contaminated with hazardous materials
posing a threat to public and animal health, groundwater, and other parts of the
environment. These hazardous materials may be released from damaged or flooded
underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks,
manure or human waste handling facilities, fertilizer and pesticide storage, agricultural
sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed
approximately 6,000 residences) entire neighborhoods can be burned to the ground.
Hazardous material release creates public health concerns which can delay the initial
steps of fire recovery, including reopening burned areas to residents and initiating debris
removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with
toxic substances due to the presence of synthetic and hazardous materials.

Probability of Future Occurrence

The probability of occurrence for a hazmat event on the CPSU – San Luis Obispo campus
can be viewed in two different ways: the history of occurrence serves as a sound
predictor of future probability assuming current risk and vulnerability factors remain
somewhat constant. For the purposes of the current estimate, no current data clearly
indicates otherwise. As such, the probability of occurrence is Low because the CPSU –
San Luis Obispo campus has not experienced hazmat events. That said, hazmat
occurrences are largely based on human error, and any changes in risk and vulnerability
factors such as a decreased vigilance in materials oversight and handling practices or
changes in the amount of chemicals or exposure will likely increase the probability on
campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the CPSU – San Luis Obispo campus. As identified by
the campus planning committee and on the hazmat map, the following vulnerabilities are

71 Source: 2018 California State Hazard Mitigation Plan, section 9.2.
present on campus: chemical and biological materials are present in the science lab, and both a rail line runs and a gas pipeline are extremely close to the campus footprint. Gases, chemicals or biological materials, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CPSU – San Luis Obispo leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CPSU – San Luis Obispo) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the San Luis Obispo County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CPSU – San Luis Obispo campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established
the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

**Identified Data Limitations**

The Cal Poly San Luis Obispo planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

---

**Landslide**

**Description of the Hazard**

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

---

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within the deposition zone and can result in downstream flooding. Post-fire debris flows often occur during the fall and winter following major summer fires.
Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 23-14. Based on the Figure below, the campus is connected to, and surrounded by areas highly susceptible to landslide.

Figure 23-14: Deep-Seated Landslide Susceptibility Surrounding Cal Poly SLO 73

---

Extent of the Hazard

Landslide events occur frequently outside of the City of San Luis Obispo, particularly along the steep slopes and coastal mountain areas. Only small landslides along unstable slopes saturated during prolonged or intense rain have occurred within the city. However, the indirect impacts of landslides in the region may cover a larger geographical extent. Based on the campus’ close proximity to the landslide hazard zone, and the history of occurrence on campus, the planning committee ranks the extent of the landslide hazard for the campus as **Moderate to High**.

History of the Hazard

The largest landslide events in the County have been associated with severe winter storms and strong El Nino events. FEMA has declared eight major disasters that included landslides, mudslides, or mud flows since 1978 in San Luis Obispo County, all of which were a result of flooding or storms.

In 2017, Fremont Hall, a dormitory on the Cal Poly SLO campus, was evacuated and closed as a result of encroaching landslide debris on a hillside east of the dormitory. The Hall remains closed.

Potential Impacts of the Hazard

CSU San Luis Obispo may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically,
landslides have occurred consistently in San Luis Obispo County and therefore are likely to occur in the future. San Luis Obispo is considered prone to deep-seated, slow-moving landslides. Given the location of the campus connected to, and surrounded by landslide susceptibility zones, and the past occurrence n campus, the planning committee ranks the probability of the landslide hazard for the campus as Possible.

Vulnerability to the Hazard

The City of San Luis Obispo is vulnerable to slope instability, especially after prolonged rainfalls. Approximately 30% of the City’s total population and seven critical facilities are exposed to high and moderate landslides. The severity is limited with limited potential impacts.

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. The campus exhibits population, building and infrastructure vulnerabilities to some degree, as well as vulnerable campus access routes. See the landslide location map in relation to the campus along with landslide severity zones identified.

Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to Cal Poly San Luis Obispo.

Vulnerability Assessment Conclusions

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may

74 City of San Luis Obispo. Retrieved 2/9/21 from https://www.slocity.org/home/showdocument?id=60
impact student and employee’s ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**

The ability to predict future landslides at the Cal Poly San Luis Obispo campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.

---

**Power Outage**

**Description of the Hazard**

San Luis Obispo, California is a city and county along the Central Coast of California. San Luis Obispo County is approximately 190 miles north of San Luis Obispo County and 230 miles south of San Francisco. San Luis Obispo is located along one of the country’s largest highways, US Route 101. It should be noted that San Luis Obispo is a seismically active area; there are a number of nearby faults including the San Andreas Fault. The Nine Sisters are a string of hills that partially run through San Luis Obispo. They are geologically noteworthy for being volcanic plugs.

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly populated areas like San Luis Obispo without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the Cal Poly San Luis Obispo (SLO) campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of Cal Poly SLO student residents in on-campus housing would also be affected by a power outage on campus and in the area.

Additionally, a severe outage to the City of San Luis Obispo or to San Luis Obispo County would also directly affect the campus and the community.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of **intentional** disruptions are:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.

- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.

- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

**Location of the Hazard**

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

**Extent of the Hazard**

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.
Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard

Cal Poly San Luis Obispo reported regularly experiencing power outages in recent years due to Public Safety Power Shut-Offs. When the campus experiences a power outage, some contingent strategies are implemented (e.g., transitioning to virtual classes).

Potential Impacts of the Hazard

Instructors, campus residents, staff and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take anywhere from several hours to days to restore operations if a significant event occurs. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016 - 2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains. Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are
projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City of San Luis Obispo and San Luis Obispo County experience such outages. As such, the probability ranking for the San Luis Obispo area is **Likely**. Since the Cal Poly SLO campus has recorded power outages, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the probability of future occurrences prompting intentional outages and creating unintentional power outages the hazard is high for the county in different areas but not specifically influencing the Cal State San Luis Obispo. Nonetheless, as discussed, campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

**Estimate of Potential Losses**

The data provided by Cal Poly San Luis Obispo does not report any value for potential losses due to power outage.

**Vulnerability Assessment Conclusions**

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Cal Poly San Luis Obispo. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.
The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

Cal Poly San Luis Obispo did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
**Volcano (Associated Air Quality)**

**Description of the Hazard**

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location”. 75

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.\(^2\)

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

**Location of the Hazard**

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of Cal Poly San Luis Obispo or San Luis Obispo County is located within a volcano hazard zone.

**Extent of the Hazard**

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While Cal Poly San Luis Obispo does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as **Low**.

The dashed lines in Figure 23-15 enclose areas where two inches or more of ashfall are possible. However, it should be noted that hazard maps are dynamic and updated periodically as research adds new information.

History of the Hazard
No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California.11 The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

Potential Impacts of the Hazard
The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As

---

Cal Poly San Luis Obispo is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at Cal Poly San Luis Obispo.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

**Probability of Future Occurrence of the Hazard**

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as *Unlikely*.

**Vulnerability to the Hazard**

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For Cal Poly San Luis Obispo, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

**Estimate of Potential Losses**

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.
Vulnerability Assessment Conclusions
Cal Poly San Luis Obispo is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations
Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

Wildfire

Description of the Hazard
While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

77 State of California Hazard Mitigation Plan, September 2018
The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially influence the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests, and other lands with high susceptibility to fire occurring throughout the state. Cal Poly San Luis Obispo is located at the base of the Santa Lucia Range. Areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur to the west, east, and north of the campus. Additionally, these fire hazard zones exist in other areas throughout San Luis Obispo County. These areas of higher fire hazards occur extensively throughout the county. Each of these hazard zones include moderate to heavy vegetation and are bordered by residential development.

The Cal Poly San Luis Obispo campus is located in central San Luis Obispo County immediately north of the City of San Luis Obispo. The area immediately to the south of the campus is residential neighborhoods. The areas of higher fire hazard bordering the
San Luis Obispo County has multiple areas considered as fire hazard zones that present direct threats of burning potential in areas that are in proximity to those hazard areas.

78 California Department of Forestry and Fire Protection, Fire and Resource Assessment Program, Fire Hazard Severity Zone Viewer, https://egis.fire.ca.gov/FHSZ/
Fire Hazards Zones surrounding San Luis Obispo County demonstrate the broader community threat that wildfires present to the population. Fire hazard severity zones are found surrounding the populated areas of the county.

Figure 23-17: Fire Hazard Severity Zone Viewer, San Luis Obispo County

Extent of the Hazard

While the threat to fire directly affecting the campus is considerable, the direct effect of fire generated smoke is also likely to occur. fires are likely to occur in close proximity to the campus generating smoke that could envelop the campus in the right atmospheric conditions. Fires that are large enough to generate volumes of smoke to cover great distances have the potential to affect the air quality of the San Francisco Bay Area including the campus. This will especially be the case in weather conditions creating strong offshore winds. The potential for this impact has been demonstrated during the summers of 2018, 2019, and 2020 as fires burned across the state and spread smoke over vast distances. Fires burning well outside of the San Luis Obispo County region have the potential to distribute smoke onto the Cal Poly San Luis Obispo (SLO) campus.

Given that the area immediately surrounding the Cal Poly SLO campus is in proximity to fire hazard zones designated as High Fire Hazard Severity Zones (HFHSZ), and that the
County and surrounding hillsides are considered to be of high fire threat including Very High Fire Hazard Severity Zones (VHFHSZ), the planning committee ranks the extent of the wildfire hazard for the campus as **High**.

Moreover, as a large number of wildfires are ignited due to human caused factors, the ability to determine when or where a wildfire might occur is impossible. Only the conditions for a wildfire can be predicted with any accuracy.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 23-24: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CLASS 1: Low Danger (L)</strong></td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td><strong>COLOR CODE:</strong> Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>CLASS 2: Moderate Danger (M)</strong></td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel -- especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td><strong>COLOR CODE:</strong> Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>CLASS 3: High Danger (H)</strong></td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common.</td>
</tr>
<tr>
<td><strong>COLOR CODE:</strong> Yellow</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.

<table>
<thead>
<tr>
<th>CLASS 4: Very High Danger (VH)</th>
<th>Fires start very easily and spread at a very fast rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Orange</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CLASS 5: Extreme (E)</th>
<th>Fire situation is explosive and can result in extensive property damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Red</td>
<td>Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</td>
</tr>
</tbody>
</table>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020.80 San Luis Obispo County also has a long history of wildfire activity primarily in the foothills and mountains throughout the county. Wildfires occurring in San Luis Obispo County have resulted in thousands of acres burned and millions of dollars in damages.

The area immediately surrounding the Cal Poly San Luis Obispo campus is in proximity to fire hazard zones designated as High Fire Hazard Severity Zones (HFHSZ). Additionally, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Cal Poly San Luis Obispo campus has experienced multiple days of poor air quality due to fires burning in Central California and neighboring counties. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including the Central Coast. Cal Poly San Luis Obispo personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

Fire has contributed significantly to San Luis Obispo County’s hazard and disaster history. Particular fires have shaped the way fire plays into preparedness, planning, response, recovery, and mitigation.

Potential Impacts of the Hazard

The location of the Cal Poly San Luis Obispo campus surrounded by areas designated as High or Very High Fire Hazard Severity Zones places a threat of flame, ember, and smoke exposure from wildfire to the campus. There is potential for fire to occur on three sides of the campus and in the surrounding hillsides composed of light to moderate fuels. The threat of these neighboring hillsides to campus structures is substantial.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction of damage
- Residential property destruction or damage
- Damage to residence halls located along borders of campus
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or disrupted transportation, lifelines, and supply routes
- Isolation from areas outside of San Luis Obispo
- Damaged or destroyed utilities

81 San Luis Obispo County Local Hazard Mitigation Plan, October 2019
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Potential for community wide evacuation
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Threat to Leaning Pine Arboretum
- Evacuation of livestock
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:
- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts on pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of San Luis Obispo County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting
hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the wildfire threat potential in the area surrounding the Cal Poly San Luis Obispo campus and hillsides along the north and east side of the campus and surrounding the City of San Luis Obispo, including the immediate proximity to Fire Hazard Severity Zones listed as “Very High”, the density of residential and commercial development, and the historic occurrences of fires, the annual probability of wildfire related damage on campus is considered Possible.

Based on the wildfire threat potential in the area surrounding Central California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered Likely.

Vulnerability to the Hazard

The Cal Poly San Luis Obispo campus is subject to direct impact from wildfire due to the campus location within a wildland-urban interface zone. The campus is identified to reside near a designated local High Fire Hazard Severity Zone. The campus is surrounded on by hillsides and open lands containing combustible vegetation. Additionally, vulnerabilities to the effects of wildfire would lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillsides and extending onto the campus or localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have significant impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures. Structures with vegetation and other combustibles near the structure increases the ability of fire to spread to buildings.
Access to the north and south using US Highway 101 servicing access to Paso Robles, Monterey, or Santa Barbara could become cutoff during fire incidents. Routes to populated areas are limited primarily to US Highway 101 other routes are smaller roadways that would also likely be impacted by fire making them impassible. The university is limited by these routes for access to and from the campus from out of the immediate area. Access for supplies, equipment, and emergency services in addition to evacuation away from the campus would likely be forced to use alternative routes if available.

The greater concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The past few summers have clearly demonstrated the reality of large wildfires producing enough smoke to fill the local areas even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. Cal Poly San Luis Obispo students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the Cal Poly San Luis Obispo campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.
Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $660,197,687. However due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in San Luis Obispo County, including wildfire incidents that have threatened or caused damages near the Cal Poly San Luis Obispo campus. The location of the Cal Poly San Luis Obispo campus surrounded by open hillsides with light to moderate vegetative fuels along the entire northern and eastern edges presents a threat of fire to the campus community and campus assets. The foothills and mountains surrounding San Luis Obispo County host environments that are ideal for the development of wildfire activity. The consequences of fires in these areas would present primary and secondary consequences to the Cal Poly San Luis Obispo campus and expose vulnerabilities on the campus and to the campus community.

The topography of the valley surrounded by mountains allows for smoke filled air to linger in the valleys of San Luis Obispo County area with the potential for unhealthy air quality depending on wind conditions. Fires in the watersheds of the nearby mountains and tributaries may damage vegetation stabilizing hillsides and result in increased sediments to be discharged into the river system and reservoirs reducing their capacity and effectiveness. Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular
populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, and Lightning)**

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to...(continued in the next page)
normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including California Polytechnic State University, San Luis Obispo (Cal Poly San Luis Obispo).

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm

84 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat
86 Retrieved on 07.17.2021 from https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions
87 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.  

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including Cal Poly San Luis Obispo), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.

**Types of Storms in California**

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage. The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California. These storms affect (in varying degrees) all CSU campuses, including Cal Poly San Luis Obispo.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.  
  
*Severe thunderstorms* are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.

- **Wind storm**: marked by high wind with little or no precipitation.

---

89 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
93 Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.94

### Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning

This hazard profile concentrates on the following types of severe weather hazards: **wind hazards** (including tornadoes), **hail**, and **lightning**. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

#### Wind Hazards

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.95 Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” 96

---

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including Cal Poly San Luis Obispo).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.
High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.97

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.98

Please note: Straight-line wind is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.99 However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

Tornadoes

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.100 This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.101 On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.102

Santa Ana Winds. A type of wind hazard that is peculiar to Southern California is called a Santa Ana Wind. Santa Ana winds are strong, topographically-enhanced, extremely dry

100 Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/
102 Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions
downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{103} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{104} (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

\end{center}

---

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.  

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and

coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.107 108 109

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.110 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.111

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.112

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.113 Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the Cal Poly San Luis Obispo campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all Cal Poly San Luis Obispo campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to Cal Poly San Luis Obispo reflect those of the surrounding community and County. As a result, all assets and people at Cal Poly San Luis Obispo are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the San Luis Obispo area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale described below, is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.114 First developed in 1805, it is still used today to estimate wind strengths.

---

114 Retrieved on 07.15.2021 from https://www.rmets.org/resource/beaufort-scale

### Near Gale
Sea heaps up and white foam from breaking waves begins to be blown in streaks along the direction of the wind.

Whole trees in motion; inconvenience felt when walking against the wind.

### Gale
Moderately high waves of greater length; edges of crests begin to break into spindrift. The foam is blown in well-marked streaks along the direction of the wind.

Breaks twigs off trees; generally impedes progress.

### Severe Gale
High waves. Dense streaks of foam along the direction of the wind. Crests of waves begin to topple, tumble and roll over. Spray may affect visibility

Slight structural damage occurs (chimney-pots and slates removed)

### Storm
Very high waves with long overhanging crests. The resulting foam, in great patches, is blown in dense white streaks along the direction of the wind. On the whole the surface of the sea takes on a white appearance. The tumbling of the sea becomes heavy and shock-like. Visibility affected.

Seldom experienced inland; trees uprooted; considerable structural damage occurs.

### Violent Storm
Exceptionally high waves (small and medium-size ships might be for a time lost to view behind the waves). The sea is completely covered with long white patches of foam lying along the direction of the wind. Everywhere the edges of the wave crests are blown into froth. Visibility affected.

Very rarely experienced; accompanied by widespread damage.
The air is filled with foam and spray. Sea completely white with driving spray; visibility very seriously affected.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{116}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the **date** that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

**Table 23-28: Fujita Tornado Scale (Pre-February 2007)**\(^{117}\)

<table>
<thead>
<tr>
<th>F-Scale Number</th>
<th>Intensity Phrase</th>

</tr>
</tbody>
</table>
Based on those extent ranking factors identified (above), the planning committee ranks the extent of the hail hazard as **LOW**.

**Extent: Lightning**

The National Weather Service (NWS) uses a Lightning Activity Level (LAL) scale to indicate the frequency and character of cloud-to-ground (C/G) lightning. The scale uses a range of 1 – 6, with 6 being the high end of the scale. Table below provides details of the LAL scale.

Table 23-31: Lightning Activity Level (LAL) Scale

<td>None</td>
</tr>
</tbody>
</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**
Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no established, objective severity scale for thunderstorms.\(^\text{121} \text{122}\) That said, according to the Glossary of Meteorology published by the American Meteorological Society (AMS), a thunderstorm is reported as light, medium, or heavy according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\(^\text{123}\)

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;\(^\text{124}\)
- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\(^\text{125}\) or

---

\(^{121}\) Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

\(^{122}\) Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm

- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder). 126 127

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

**History of the Hazard**

Severe weather hazards have been an annual occurrence in San Luis Obispo County and on the Cal Poly San Luis Obispo campus. Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.128 For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.129 To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in San Luis Obispo County since 1996.\textsuperscript{130} Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\textsuperscript{131}

- **High Wind**: at least 45 events, or approximately 1.78 events per year
- **Strong Wind**: at least 0 events, or 0 events per year
- **Thunderstorm Wind**: at least 12 events, or approximately 0.47 events per year
- **All Wind Hazard events** (excluding Tornadoes): at least 51 events, or approximately 2.01 events per year. (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in San Luis Obispo County, there have been at least 51 wind hazard events since 1996, excluding tornadoes. That translates to an approximate average historical frequency of occurrence of 2.01 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 57 events) and simultaneous Database searches of all severe weather hazard events (i.e., 51 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;") and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for San Luis Obispo County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{132} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 51 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for San Luis Obispo County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that San Luis Obispo County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop losses, property damage estimates have totaled approximately $4,000,000.

**Tornado Wind Hazards**

\textsuperscript{130} National Climatic Data Center. Storm Events Database. Retrieved 07.19.2021 from https://www.ncdc.noaa.gov/stormevents/

\textsuperscript{131} National Climatic Data Center. Storm Events Database. Retrieved 07.19.2021 from https://www.ncdc.noaa.gov/stormevents/

Information from the NCEI Storm Events Database indicates that since 1996, there have been 2 reported events of tornadoes in San Luis Obispo County, which translates to approximately 0.08 tornado events per year. The severity rating of both tornadoes was F0/EF0.

**Historical Tornado Hazard Losses for San Luis Obispo County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that San Luis Obispo County has experienced since 1996 have produced no deaths, injuries, property damage, or crop damage.133

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 5 reported events of hail in San Luis Obispo County, which translates to approximately 0.20 hail events per year. (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of six (6) reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from San Luis Obispo County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for San Luis Obispo County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that San Luis Obispo County has experienced since 1996 have produced no deaths, injuries, property damage, or crop damage. (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in San Luis Obispo County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been no reports of lightning hazard events in San Luis Obispo County.

**Historical Lightning Hazard Losses for San Luis Obispo County since 1996**

Because no lightning hazard events have been reported in San Luis Obispo County since 1996, there are no lightning-related deaths or injuries, or property or crop damages in the County.

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

133 National Climatic Data Center. Storm Events Database. Retrieved 07.31.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Tornado&beginDate_mm=01&
Information obtained from the NCEI Storm Events Database indicates that there have been 58 occurrences of the severe weather hazard in San Luis Obispo County. This translates to 2.29 severe weather hazard occurrences per year.\textsuperscript{134}

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 65 events) and simultaneous Database searches of all severe weather hazard events (i.e., 58 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for San Luis Obispo County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{135} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 58 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical, Aggregated Severe Hazard Losses for San Luis Obispo County since 1996

According to the NCEI Storm Events Database, the severe weather events that San Luis Obispo County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damage, and property damage estimates have totaled approximately $4,000,000.\textsuperscript{136} \textit{It is important to note that for all San Luis Obispo County severe weather hazard events recorded on the Storm Events Database, all estimated property damages have been caused by wind hazard events alone.}

Wind Hazards Not Included in the NCEI Storm Events Database

\textit{Santa Ana Winds}

Santa Ana wind events occur at least twice per month from October through April. From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textit{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6
days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.137 138

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Diablo Winds

Diablo wind events occur approximately 2.5 events per year. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.

---

The following figure shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{141}

Figure 23-21: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\textsuperscript{142}

\textbf{Sundowner Winds}

Strong sundowner wind events occur approximately 2-3 times per year. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\textsuperscript{143}

\textbf{Historical Frequency of All Severe Weather Hazards}

Table below shows the average historical frequency of severe weather hazard events for San Luis Obispo County since 1996.)

\begin{itemize}

* Note: The Diablo and Sundowner wind hazards are not present in San Luis Obispo County. They are included here for information purposes only.

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within Cal Poly San Luis Obispo campus areas are at risk from the effects of severe weather hazards.

Wind Hazards (Including Tornadoes)

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the Cal Poly San Luis Obispo campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.
Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

According to the 2019 San Luis Obispo County Multi-Jurisdictional Hazard Mitigation Plan, high wind hazards (including tornadoes) are “adverse weather” hazards that are considered to be of low significance, and therefore to have a minimal potential impact on the County and (by extension) the Cal Poly San Luis Obispo campus.\textsuperscript{144} However, thunderstorms – which are accompanied by high winds – are considered to be of medium significance, and therefore to have a moderate potential impact on the County and (by extension) the Cal Poly San Luis Obispo campus. (Please note: In the Plan, thunderstorms are grouped together with heavy rain, hail, lightning, dense fog, and freeze into one large “adverse weather” category.)

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

According to the 2019 San Luis Obispo County Multi-Jurisdictional Hazard Mitigation Plan, hail hazards are “adverse weather” hazards that are considered to be of medium significance, and therefore have a moderate potential impact on the County and (by extension) the Cal Poly San Luis Obispo campus. (Please note: In the Plan, hail is grouped together with thunderstorms, heavy rain, lightning, dense fog, and freeze into one large “adverse weather” category.)

**Lightning**

Lightning strikes the United States about 20-25 million times a year.\textsuperscript{145} Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.\textsuperscript{146} Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500

\begin{footnotes}
\end{footnotes}
worth of payouts per year.\textsuperscript{147} (Commercial claim payouts for lightning losses for the U.S. were not available.)

According to the 2019 San Luis Obispo County Multi-Jurisdictional Hazard Mitigation Plan, lightning hazards are “adverse weather” hazards that are considered to be of medium significance, and therefore have a moderate potential impact on the County and (by extension) the Cal Poly San Luis Obispo campus.\textsuperscript{148} (Please note: In the Plan, lightning is grouped together in one large “adverse weather” category with thunderstorms, heavy rain, hail, dense fog, and freeze into one large “adverse weather” category.)

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The 2019 San Luis Obispo County Multi-Jurisdictional Hazard Mitigation Plan states that there is between a 10% and 100% chance that all “adverse weather” hazards profiled here (including wind, tornado, hail and lightning) will occur in the future.\textsuperscript{149} However, according to the NCEI Storm Events Database, severe weather wind hazards have occurred in San Luis Obispo County significantly more than once annually – at an average occurrence of 2.01 times per year since 1996. While the severe weather hazard is a non-spatial hazard that affects all areas of the Cal Poly San Luis Obispo campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the Cal Poly San Luis Obispo campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2019 San Luis Obispo County Multi-Jurisdictional Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the Cal Poly San Luis Obispo campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for Cal Poly San Luis Obispo is **HIGHLY LIKELY**. See the table below for probabilities of future occurrence for component severe weather hazards for the County and the campus.

---

\textsuperscript{147} Retrieved on 07.21.2021 from https://www.iii.org/table-archive/20504

Vulnerability to the Hazard

People, structures, and assets on the Cal Poly San Luis Obispo campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The Cal Poly San Luis Obispo campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire Cal Poly San Luis Obispo campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

Table 23-33: Severe Weather Hazard Probabilities of Future Occurrence for San Luis Obispo County and Cal Poly San Luis Obispo

23-137
All structures within the Cal Poly San Luis Obispo campus are at risk from severe weather. There are approximately 158 buildings on the campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $660,197,687 for 113 of the buildings, and are unknown for the remaining 45 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at the Cal Poly San Luis Obispo campus varies throughout the day. As of Fall, 2019, Cal Poly San Luis Obispo had 21,242 students and 2,871 faculty and staff. All are at risk from severe weather events, with 24,113 being directly vulnerable in this scenario.

**Vulnerability Assessment Conclusions**

Severe weather presents a variety of hazards to the Cal Poly San Luis Obispo campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to Cal Poly San Luis Obispo.

It is evident that the Cal Poly San Luis Obispo campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

**Identified Data Limitations**

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated

150 Retrieved on 07.19.2021 from https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
23.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU San Luis Obispo campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.
Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”

Table 23-34: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
</table>
| Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning? | • LGBTQI populations  
• Students without financial aid  
• Populations experiencing homelessness  
• International students  
• Student exchange participants  
• Access and functional needs |
| Which population groups are most difficult to reach in an event?          | Students relying on social media for news and updates  
Economically disadvantaged populations without internet connections |
| Which population groups have little/limited support networks if impacted by an event? | N/A |

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered
an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus?
  
  Responses were summarized as **Very High, High, Medium, Low**

- Is this factor reflected in the emergency plans and processes for your campus?
  
  Responses were summarized as **Yes, No, In Progress, NA**

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Health and wellness is talked about in the EOC, with the emergency response team, and reflected in the plans.

- Access and functional needs accessibility on the website is in compliance though can improve. Quarterly updates are given to the EOC that lists individuals; AFN organization has a member that serves as a disability officer in the management section.

- Racial equity is a high issue of concern and is reflected in the plans.

- Communications is not considered an issue of concern except that student don’t tend to read emails.

- Visa regulations get changed for the international students and is a major concern.

- For international and immigrants/immigration status issues, are not reflected in the planning documents and referred to the study body as a whole, not “who is who.”

- Elements reflecting LGBTQI concerns are contributed to the emergency plans through designated liaisons, task forces and planning groups.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\(^{152}\) Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\(^{153}\) Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the

---

major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.154

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic,

---

and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.”

Flood

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such

---

as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. 156

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural health and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, anger, sadness and grief. 157 Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms. These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

Landslides

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied

buildings which makes it a function of structural vulnerability and therefore, indirect. The
degree of vulnerability to landslides by an individual considered at high risk, or even the
general populations, also depends on human behavior, including many of the traditional
social factors that are difficult to measure such as situational awareness, prior knowledge
of hazards, and decision-making capabilities.158

Landslides can result in primary lifeline failures through the loss of roads or power and
communication lines. Transportation routes are often expensive to clean up, and
prolonged obstruction can disrupt the movement of people and goods. Risk from
landslide relates to earthen and infrastructural losses. The degree of vulnerability to these
events and their impacts depends on human behavior and the traditional social factors
such as situational awareness, prior knowledge of hazards, social capital and decision-
making capabilities, as well as increased vulnerability due to social factors, such as racial
and economic disparities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events,
such as those experienced throughout the state over the recent years. Many businesses
close, including gas stations, grocery stores, and local retail establishments. These
impacts may deeply impact students dependent on support jobs, as well impacting family
members of campus staff and faculty. PSPS increases risks to the public due to inability
to use medical devices, spoilage of food and medicines, and disruption to infrastructure,
such as supply of clean water and electricity used to run home medical equipment, such
as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest,
but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk.
Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And,
in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent
wildfires have demonstrated that some demographics are disproportionately affected.
Native Americans are six times more likely to be affected than white people. Blacks and
Hispanic people are 50 percent more vulnerable. These values take into account the
likelihood of a community being affected and the greater difficulty of that community to
recover. These statistics reflect the lack of access to resources to pay for insurance, to
rebuild and recover, to implement fire safety measures, and to access other resources.
Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs

---

29, 2021.
Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be

envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.
Section 24

California State University, San Marcos

24.1 University Profile

University History

Since its founding in September of 1989, California State University San Marcos has focused on preparing future leaders, building great communities and solving critical issues. Located on a 306-acre hillside overlooking the city of San Marcos, CSUSM is the only public four-year comprehensive university serving North San Diego, Southwest Riverside and South Orange counties. CSU San Marcos opened in August of 1990 in rented office spaces with 448 juniors and seniors, a dozen faculty members and nine majors. In 1991, seven students were awarded the first Bachelor of Arts degrees in campus history. And, in fall 1992, the permanent campus opened following the completion of Craven Hall, Academic Hall and Science Hall I. CSU San Marcos has substantially grown since 2003 adding a building every year for the following decade.

CSU San Marcos offers 62 bachelor’s degrees, 15 master’s degrees, an Ed.D. program, and 13 teaching credentials. The university has four colleges: the College of Business Administration; the College of Science and Mathematics; the College of Humanities, Arts, Behavioral and Social Sciences; and the College of Education, Health and Human Services.

University Governance

The campus president is the chief executive officer of the university and maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the system-wide Executive Council. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty.

University Mission

“California State University San Marcos focuses on the student as an active participant in the learning process. As a Carnegie classified "community engaged" university, CSUSM students work closely with a faculty whose commitment to sustained excellence in teaching, research, and community partnership enhances student learning. The university offers rigorous undergraduate and graduate programs distinguished by exemplary teaching, innovative curricula, and the application of new technologies. CSUSM provides a range of services that respond to the needs of a student body with diverse backgrounds, expanding student access to an excellent and affordable education. As a public university, CSUSM grounds its mission in the public trust, alignment with regional needs, and sustained enrichment of the intellectual, civic, economic, and cultural life of our region and state.”
CSU San Marcos is dedicated to intellectual engagement, community, integrity, innovation and inclusiveness and focuses on these priorities to reach its strategic planning goals and mission.

University Location

CSU San Marcos is conveniently located in North San Diego County - only a short drive from the City of San Diego, Riverside County and Orange County.

University Population

CSU San Marcos exceeds a population of 16,000 students. Latino students make up 49% of the student population. White students are second in population at 27% In 2020, 47% of students received Pell Grants.

24.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate ..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the
community so that mitigation options can be considered in future land use decisions.

**Requirement §201.6(c)(2)(iii):** For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

### 24.3 Hazard Identification and Risk Assessment

**Overview of California State University, San Marcos History of Hazards**

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

**Hazard Identification**

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 24-1 (following).

### Future Occurrence Probability

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- Highly Likely - 76%-100% that the hazard would occur annually.
- Likely - 50%-75% that the hazard would occur annually.
- Possible - 11%-49% that the hazard would occur each annually.
- Unlikely - 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent.¹ They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions.² The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.³

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)⁴

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 24-2 below.)

**Descriptions of Identified Communicable Disease Hazards at CSU San Marcos**

CSU San Marcos has identified one (1) communicable disease hazard that has had the greatest impact on campus – COVID-19. The following is a brief description of the communicable disease hazard at CSU San Marcos.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.
The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It’s not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.  

Location of the Hazard

Communicable diseases have the potential to affect the entire CSU San Marcos (CSUSM) planning area equally. As a result, the communicable disease hazard can be found both at the main CSUSM campus is located San Marcos, CA (San Diego County), and at the CSUSM satellite campus in Temecula, CA (Riverside County). Because of the ubiquitous nature of many communicable diseases students, faculty, staff at (and visitors to) both CSUSM locations are at risk of exposure to the communicable disease hazard.  

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. Table 24-4 shows the number of students that were living in CSU-campus-owned housing in Fall,

---

7 California State University. About CSU. Retrieved 4.29.2021 from: https://www2.calstate.edu/csu-system/about-the-csu
2019, prior to the CVID-19 pandemic. For CSU San Marcos, approximately 11% of its 14,519 enrolled students (or 1,597 students) reside in student housing.  

**Extent of the Hazard**

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 24-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

The Extent of CSU San Marcos Communicable Disease Hazards Except COVID-19:

Besides COVID-19, there was no information provided on other communicable disease hazards on campus.

The Extent of CSU San Marcos COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3. 11

CSU-campus-specific COVID-19 case data for CSU San Marcos can be found in the History of the Hazard section below.

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 113 cases of COVID-19 at CSU San Marcos. Most communicable disease data are maintained by at the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a

result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 24-5- and 24-6 show campus-level and County-level COVID-19 Case data for CSU San Marcos. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the CSU San Marcos campus. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if

those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU San Marcos students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic, and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU San Marcos) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 24-6: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not</td>
</tr>
</tbody>
</table>

usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)

Table 24-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall into these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 24-7: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<tbody>
<tr>
<td>These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.</td>
<td></td>
</tr>
</tbody>
</table>

**Probability of Future Occurrence of the Hazard**

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency. Table 5-12 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:
Table 24-8: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the CSU San Marcos campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. As of Fall 2019, the CSU -San Marcos System had 14,519 students and additional faculty and staff. Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree in the current COVID-19 pandemic on the San Marcos campus. 17,18

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU San Marcos) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities. 19 The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system.

17 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx
18 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
(Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

Economic Impact of COVID-19 Pandemic on CSU Financial Health

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 24-2 below for the economic impact to the CSU – San Marcos campus). Several CSU campuses saw refund losses surpass $10 million. (See Figure 24-2.)

Figure 24-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs

During Spring Semester, 2020, campus shutdowns, the shift to remote learning, shrinking revenue from sources like dorm fees and student bookstores, and changes in enrollment patterns across the system unrelated to COVID-19 all hit the California State University system simultaneously with well over a $300 million loss from reduced revenues and from new costs.

---

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 24-11.) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. *If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time.* This scenario would likely overwhelm available on-campus medical services and could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 24-12 below for the “10% outbreak scenario” projections for the CSU – San Marcos campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system, including CSU - San...
Marcos. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).
**Dam and Levee Failure**

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtopping to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

---

Location of the Hazard

San Diego County is home to a variety of flood control facilities and levee systems mostly along the base of the various mountains and hills throughout the county. Levees have been constructed along flood control channels in the County but not in proximity to CSU San Marcos. The CSU San Marcos campus is in proximity to one relatively small dam a mile south of the campus. The campus is not in proximity to rivers or flood control channels lined with levees.

Figure 24-3: Dams and Levees near San Marcos

There are a number of dam facilities scattered throughout the hills east and south of San Marcos. These facilities do not have a direct impact on the campus but may provide hazards to transportation routes in and out of the campus and may affect areas in which members of the campus community reside. The CSU San Marcos campus lies outside of dam inundation zones for these facilities.
Figure 24-4: San Marcos Dam Breach Inundation Map

[Map of San Marcos Dam Breach Inundation with CSU: San Marcos Inundation highlighted.]

27 California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.
• High hazard potential dams may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
• Significant hazard potential dams are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
• Low hazard potential dams are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

</thead>
<tbody>
<tr>
<td>San Marcos</td>
<td>San Marcos</td>
<td>4,818af</td>
<td>High Hazard</td>
</tr>
</tbody>
</table>

The CSU San Marcos campus lies outside of the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the CSU San Marcos campus is expected to remain out of an area affected by water inundation. The inundation area is expected to spread water to the west towards Lake San Marcos. There are multiple secondary transportation corridors and residential neighborhoods that lie within the dam inundation zones that could compromise transportation routes and areas the campus community reside or work. Based on these factors, the planning committee ranks the extent of the hazard as Low.

**Extent – Levee Failure**

Levees are used along numerous flood control channels and other waterways including portions of the San Marcos Creek. The CSU San Marcos campus lies outside of the levee flood protected area. Transportation routes accessing the campus cross into levee protected zones. In the event any of these channels were flowing at elevated levels and a failure of a levee were to occur, the community surrounding the campus would likely experience flood related damages. While the campus would not experience direct impacts, this specific hazard could alter the ability of the campus to maintain operations as damages would be extensive. Depending on the location of a breach, the campus community could be heavily affected with the loss of life and homes, access to campus would be limited, and student financial capacity to support ongoing education being diminished. However, it should be noted that levees undergo regulated monitoring, maintenance and inspections. Based on these factors, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

There are no records of dam or levee failures in areas that present a threat to the CSU San Marcos campus. San Diego County has experienced the following dam failures:

Potential Impacts of the Hazard

**Dam Failure Impacts**

Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Potential impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

**Levee Failure Impacts**

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would
vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering

Probability of Future Occurrence of the Hazard

San Diego County is determined to be at risk from dam and levee failure in many parts of the county. The location of the CSU San Marcos campus is one mile to the north and lower in elevation to the San Marcos Dam / South Reservoir demonstrating that the potential exists for future dam or levee related issues. However, the dam inundation zone for the South Reservoir turns to the north east and away from the campus. The campus is ¾ of a mile from the boundary of the dam inundation zone. There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on historical experience and occurrences, the likelihood of this hazard is low.

The CSU San Marcos, Temecula campus is ¼ mile away from the dam inundation zone for the Diamond Valley Lake that is 13 miles northeast of the campus and 2 miles from the dam inundation zone for the Skinner Reservoir. The campus is 1/8 of a mile from the Vail Lake Dam inundation zone. There are no identified levees in proximity to the Temecula campus and thus the campus is outside of any levee protected zone.

The probability of future occurrence for both dam and levee failures is Unlikely. 

Vulnerability to the Hazard

Given high priority monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. As such, vulnerability is tied to the consistency of these practices, and, therefore, is not considered to be truly vulnerable on a daily basis. However, in the unlikely event of a catastrophic failure, the effects of flooding from compromised dams and levees would not directly impact the campus but would most likely affect members of the campus community only in terms of disruption to regional
transportation networks and services and the amount of time to respond to the needs of the campus community prior to inundation will be limited.

Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in the vulnerability of numerous displaced individuals and households. The lack of flood insurance will cause additional extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the CSU San Marcos campus will vary depending on when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to dam or levee failure are $217,777,651. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU San Marcos.
Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the CSU San Marcos campus, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences would be catastrophic to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.
**Drought**

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
• **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU –San Marcos) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified throughout San Diego County where the campus is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to the campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously in the state, with 80-100% of the state impacted for 12 of the last 20 years. 29

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout San Diego County (including the planning area) and across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire planning equally, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. In addition, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. These effects though rare, are issues of concern for the campus over the long term.[1]

---

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

30 United States Drought Monitor. *Drought Classification*. Retrieved 05.04.2021 from: [https://droughtmonitor.unl.edu/About/AbouttheData/DroughtClassification.aspx](https://droughtmonitor.unl.edu/About/AbouttheData/DroughtClassification.aspx)
Fire season lasts year-round; fires occur in typically wet parts of state; burn bans are implemented

Ski and rafting business is low, mountain communities suffer

Orchard removal and well drilling company business increase; panning for gold increases

Low river levels impede fish migration and cause lower survival rates

Wildlife encroach on developed areas; little native food and water is available for bears, which hibernate less

Water sanitation is a concern, reservoir levels drop significantly, surface water is nearly dry, flows are very low; water theft occurs

Wells and aquifer levels decrease; homeowners drill new wells

Water conservation rebate programs increase; water use restrictions are implemented; water transfers increase

Water is inadequate for agriculture, wildlife, and urban needs; reservoirs are extremely low; hydropower is restricted

Fields are left fallow; orchards are removed; vegetable yields are low; honey harvest is small

Fire season is very costly; number of fires and area burned are extensive

Many recreational activities are affected

Fish rescue and relocation begins; pine beetle infestation occurs; forest mortality is high; wetlands dry up; survival of native plants and animals is low; fewer wildflowers bloom; wildlife death is widespread; algae blooms appear

Policy change; agriculture unemployment is high, food aid is needed

Poor air quality affects health; greenhouse gas emissions increase as hydropower production decreases; West Nile Virus outbreaks rise

Water shortages are widespread; surface water is depleted; federal irrigation water deliveries are extremely low; junior water rights are curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor;

History of the Hazard

Although previous occurrence of drought is not identified specifically for the campus, drought has been so prevalent in California that its presence is almost ubiquitous and continuous, including the CSU - San Marcos footprint.
According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential. 31

Best available data does not identify a timeline of historical occurrences specific to the campus, but the water table at the campus farm is receding, indicating the recent occurrence of drought on campus.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 32

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017. 33

Figure 24-6: Periods of Drought in State of California, 2001 – 2021 34

---

Given the ubiquitous nature of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the CSU - San Marcos campus planning area:

**2012 – 2017** – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state's agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.  

### Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant impact associated with drought across the CSU - San Marcos campus planning area is the historic and potential reduction in water availability for the municipal area tied to each campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - San Marcos to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of agricultural research crops and field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. However, the wildfire hazard is analyzed separately in this plan. (See wildfire hazard).

---

35 National Oceanic and Atmospheric Administration National Centers for Environmental Information. *State Climate Summaries: California.* Retrieved 05.04.2021 from: [https://statesummaries.ncics.org/chapter/ca/](https://statesummaries.ncics.org/chapter/ca/)

In reviewing the occurrences of drought for CSU - San Marcos and San Marcos, CA, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2014-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - San Marcos, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data are currently available for tree mortality on campus; however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.

At present, drought related damage to campus buildings and infrastructure at CSU - San Marcos has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - San Marcos is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability.

for all usage contexts, including CSU - San Marcos. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Probability of Future Occurrence of the Hazard

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that CSU - San Marcos lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

---

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - San Marcos campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - San Marcos planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2 million acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

Vulnerability of Populations

The historical and potential impacts of drought on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat,
negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerability measures apply to the students, faculty and staff of the CSU – San Marcos campus.

**Property Vulnerability**

The historical and potential impacts of drought on property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerability measures apply to the properties of the CSU - San Marcos campus.

**Natural Environment Vulnerability**

The historical and potential impacts of drought on the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping the impact of drought throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought impacts to state and CSU - San Marcos’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However. drought related losses to the City of San Marcos and the surrounding region such as crop loss and cost increases for water resources have
re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

Vulnerability Assessment Conclusions

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

Identified Data Limitations

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

Fault Rupture – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

Liquefaction – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

Subsidence - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local
environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

Location of the Hazard

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU San Marcos is located in northern San Diego County bordering Escondido. In general, fault systems surround and traverse through San Diego County including the area of CSU San Marcos. Throughout the valleys the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 80-85 miles east of the CSU San Marcos campus. In addition to the San Andreas Fault, San Diego County is home to or near additional fault systems with the potential to generate strong ground shaking. The Elsinore Fault extends across the northern portions of the county in a southeast to northwest direction. The Newport-Inglewood Fault is another southeast to northwest fault 13 miles west of the campus paralleling the coastline. The San Jacinto Fault extends from the Salton Sea to the Cajon Pass approximately 40-45 miles northeast of the campus. There are numerous additional faults in the area on all sides of the campus.
The CSU San Marcos campus does not reside within areas designated to be liquefaction zones. However, substantial areas of the community surrounding the campus reside within the liquefaction zones including access routes into and out of the campus. These zones mostly follow the creek channels. This includes Interstate 15, State Route 78, and South Twin Oaks Valley Road. The liquefaction zone generally follows the path of the San Marcos Creek.

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity, and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and
evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Although earthquake history, damages and shaking potential in the San Diego County area are fairly extensive, the campus does not reside in a liquefaction zone. Nevertheless, the impacts of a major earthquake would be felt beyond the campus and have long reaching effects. The risk of casualties and damages would likely extend to the homes and workplaces of members of the campus community including students, staff, and faculty. As such, the planning committee ranks the extent of the earthquake hazard as Moderate.

History of the Hazard

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. San Diego County also has a long history of earthquake activity. The entire area of San Diego County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The May 18, 1940 Imperial Valley Earthquake became the largest seismic event in the Imperial Valley at the time. The Imperial Valley Earthquake resulted in 8 people being killed, multiple injuries, and $6 million in damages. The earthquake caused extensive damage to structures, the transportation infrastructure, utility systems, irrigation systems, and critical facilities. The Imperial Fault displayed a surface rupture extending of at least 25 miles. The earthquake was felt as far away as Los Angeles and Tucson.

43 San Diego County Mulit-Jurisdictional Hazard Mitigation Plan, October, 2017
The April 8, 1968 Borrego Mountain Earthquake shook a large part of southern California. The earthquake caused extensive damage across southern California. The earthquake resulted in extensive infrastructure damages, power lines being severed, roadway damages, and structural damages. Ground displacement was found along the Superstition Hills Fault miles from the epicenter. The earthquake was felt as far away as Yosemite Valley, Fresno, and Las Vegas.

**Potential Impacts of the Hazard**

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils to the north of the campus along San Marcos Creek presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the San Diego area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near San Marcos could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near San Marcos could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader San Diego County region limiting immediate assistance that the campus may normally expect.

Local impacts to CSU San Marcos campus caused by an earthquake could include:

- Damage and secondary fires to industrial buildings to the west of campus
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway system
- Structural damage to bridges
- Landslides to hills surrounding San Marcos
- Potential liquefaction damage to areas near the San Marcos Creek and Twin Oaks Valley Channel
- Potential isolation among on-campus residents
- Structural damage to flood control and drainage systems
- Damage to the South Lake Reservoir Dam
- Structural damage to campus academic and support buildings
- Structural damage to parking structure
- Structural damage to residence halls resulting in displaced student populations
- Potential isolation among on-campus residents
- Structural damage to nearby residences and apartment complexes
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the San Diego County fault systems surrounding San Marcos is included in the following table.

Based on the earthquake shaking potential in the San Diego County region, the proximity to the above listed fault systems, the probability of seismic ground shaking generating damage is considered Possible.

44 San Diego County Multi-Jurisdictional Hazard Mitigation Plan, October 2017
45 Southern California Earthquake Center, Earthquake Information, [https://scedc.caltech.edu/earthquake/faults.html](https://scedc.caltech.edu/earthquake/faults.html)
Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of CSU San Marcos places the campus in a suburban community near residential, commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to San Marcos generally surround the city but do not cross into the city including near the CSU San Marcos campus. However, the proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the CSU San Marcos campus will vary depending on when the earthquake were to strike. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In
earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $217,777,651.

**Vulnerability Assessment Conclusions**

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater San Diego County region and the CSU San Marcos campus. Each of the earthquake generated effects will vary widely based
on the intensity of the earthquake, location of the epicenter, proximity to people and
development, time of day and year, the soil composition under the impacted structures,
building construction, among others. In any case, the potential for a major earthquake
exists affecting the campus and causing extensive challenges to the CSU San Marcos
campus and community.

In the event that a major earthquake were to strike along the many fault systems
surrounding San Marcos, the effects could be significant to the campus community and
campus operations. The widespread impacts generated by a major earthquake would
extend the effects of casualties, damages, and other impacts to the broader San Diego
County region creating large-scale regionwide needs for critical assistance and a heavy
demand on limited emergency resources. The threat and impacts presented to the campus
will be shared with the campus community from their homes and places of work. The
campus will likely be required to address critical needs independently during early phases
of the disaster.

The campus population is additionally vulnerable to the effects of major ground shaking
that are far reaching. The psychological and social impacts a major earthquake will give
rise to will potentially harm individuals and cause tremendous fear. The willingness to
return indoors may be hampered especially as after-shocks continue. These effects are
magnified for populations having specific vulnerabilities or access limitations.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of a
complete inventory of building construction types to include status of earthquake
retrofitting. HAZUS generated analysis is focused on the broader community level versus
fine-tuning the analysis to the micro-level for facilities such as a university campus.

Erosion

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of
the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from
one place to another.” Erosion may occur in areas of streams and rivers, along bluffs,
around immovable objects (such as buildings or bridge abutments), or as a cascading
result of other natural hazards, such as earthquakes or wildfires. When erosion occurs
along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually
and can be difficult to recognize. In contrast, the impacts of short-term events, such as

storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. As such, for the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the CSU San Marcos campus with erosion-prone characteristics. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area. Areas on campus with little to no vegetation have been identified which resulted from a 2014 fire in the area. These areas are susceptible to erosion.

Extent of the Hazard

While there is no published scale of severity or extent for this geologic hazard on the CSU San Marcos campus, erosion is likely to occur if conditions are favorable. Such conditions are favorable in areas on campus with little to no vegetation, and are being monitored. As such, the planning committee ranks the extent of the hazard as Moderate.

History of the Hazard

After a 2014 fire in the area, there was concern regarding erosion hazards due to the lack of vegetation. However, there are no recorded incidents of erosion on the CSU San Marcos campus.

Potential Impacts of the Hazard

Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the Salida current and potential extent of erosion on campus, the probability of at least a limited degree of erosion in the future is High.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU San Marcos infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. In addition to areas
on campus with little vegetation, CSU leadership would consider performing an analysis to identify such at-risk buildings, infrastructure, slopes and soil types in the future.

In the wider San Marcos community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

Vulnerability Assessment Conclusions

While the ability to predict future erosion on the CSU San Marcos campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

Heat

Description of the Hazard

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.48

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.49 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the

temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.\textsuperscript{50} In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.\textsuperscript{51}

Location of the Hazard

Extreme heat events are a non-spatial hazard and may occur throughout the CSU San Marcos campus.

Extent of the Hazard

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the high 70s to the high 80s in San Marcos. That said, multiple extreme heat events have occurred with 12 events in just the last two years. In addition, the 2006 heat wave with temperatures reaching 119 degrees stands as a marker for how severe the hazard may become in the future. Based on these factors, the planning committee ranks the extent of the hazard for the campus as Moderate to High.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria.\textsuperscript{52} In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 24-9 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

\textsuperscript{52} National Weather Service. \textit{Heat}. Retrieved 01.22.21 from: https://www.weather.gov/bgm/heat
Figure 24-9: Methodology for Determining Heat Index

As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.

</tr>
</tbody>
</table>

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been multiple excessive heat events in the City of San Marcos and in San Diego County, with a dozen events occurring just in 2019 and 2020. The extended period of excessive heat across Southern California in the summer of 2006 is particularly notable. Heat index values in the region reached as high as 119° F. This heat wave led to the development and adoption of San Diego County’s Excessive Heat Preparedness and Response Plan, which was just recently updated and reissued in a consumer version in August 2020. 54

Potential Impacts of the Hazard

CSU San Marcos may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather. In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

There have been multiple extreme heat events in San Diego County that have affected the City of San Marcos, including three in the past year. It is Highly Likely that the hazard will occur annually.

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more

likely to suffer illness or death as a result.\textsuperscript{55} This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Given the frequency of heat waves and excessive heat events, CSU San Marco is aware of the potential for heat-related illnesses and other negative impacts. However, the campus’s Emergency Procedures Plan does not address specific responses or operations during a heat event. Emergency procedures for power outages, which can occur as a result of a heat wave or excessive heat event – are included in the plan.

Because this is a hazard that the campus experiences with regularity – and will continue to experience – CSU San Marcos may wish to make resources, plans, and procedures for heat events clearer in its Emergency Procedures Plan in order to better address the risks and vulnerabilities of heat-related illnesses and other impacts.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the CSU San Marcos campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.\textsuperscript{56}

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

\textsuperscript{55} Centers for Disease Control and Prevention. \textit{Heat and People with Chronic Medical Conditions}. Retrieved 03.13.21 from https://www.cdc.gov/disasters/extremeheat/medical.html

Flood

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.
- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric Rivers**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Location of the Hazard

San Marcos lies within the San Marcos Creek Valley in northern San Diego County. Along the southern edges of San Marcos are low rising hills that form the backdrop to the CSU San Marcos campus. These include the San Elijo Hills which provide a potential for developing water run-off during heavy precipitation events. There are a number of flood retention basins and flood control channels along the base of these hills to protect these San Diego County communities including San Marcos. The area surrounding the campus is a combination of developed suburban environment predominately consisting of residential and commercial land uses and open hillsides.

57 National Oceanic and Atmospheric Administration, “What are atmospheric rivers?”, https://www.noaa.gov/stories/what-are-atmospheric-rivers
The CSU San Marcos campus is located ½ mile south of the San Marcos Creek that flows from Escondido through San Marcos towards the ocean. The San Marcos Creek receives the majority of its water from precipitation during the winter months. The San Marcos Creek does not contribute to a direct flood hazard to the campus but may compromise access routes to the campus. The South Lake drainage extends to the northwest of the campus towards Discovery Lake. The South Lake drainage does not contribute to a direct flood hazard to the campus but may compromise access routes to the campus. The entire CSU San Marcos campus sits within a Special Flood Hazard Area (SFHA) Zone X: Area of Minimal Flood Risk designation on the Flood Insurance Rate Map. Extending down the San Marcos Creek are areas that reside in a Zone AE: 1% Annual Chance Flood Hazard.

Extent of the Hazard

The CSU San Marcos campus is entirely located in a designated Zone X: Area of Minimal Flood Hazard. The access routes into and out of the campus servicing locations in all directions are also found in areas primarily designated as Zone X: Area of Minimal Flood Hazard. Access routes to the north at the point of crossing the San Marcos Creek are
located in designated Zone AE: 1% Annual Chance Flood Hazard. Due to the location of the campus, the extent of the hazard is limited on campus, though flooding in the community at large could disrupt nearby transportation routes. As such, the planning committee ranks the extent of the hazard as **Low**.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBMs), Flood Insurance Rate Maps (FIRMs), and Flood Boundary and Floodway Maps (FBFMs). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

**Table 24-21: Flood Zone Designations and Descriptions**

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised map in place of Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, BFEs derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
</tbody>
</table>
Zone AH 1% Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.

Zone AO 1% Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.

Zone X (shaded) 0.2% Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.

Zone X (unshaded) Undetermined Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.

History of the Hazard

Flooding in San Marcos and the broader San Diego County regions have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the CSU San Marcos campus.

58 San Diego County Multi-Jurisdictional Hazard Mitigation Plan, October 2017
Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source.

Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.
Probability of Future Occurrence of the Hazard

San Diego County is determined have considerable portions of the county to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common in the San Diego area with winter storms that are saturated with subtropical moisture. The area surrounding the CSU San Marcos campus does not generally promote conditions for flood waters to accumulate. The majority of the campus is elevated on a hillside above the San Marcos Creek and urban core of the City of San Marcos. However, access to the campus from the valley floor may become compromised in flooding events along the San Marcos Creek. The campus is located within a Zone X (Area of Minimal Flood Hazard). The San Marcos Creek is located ½ mile north of the campus and is located within the Zone AE Special Flood Hazard Area (Area Inundated by 1% Annual Chance of Flooding). There are specific buildings and areas of the campus that have a greater risk for isolated flooding. However, the area is subject to isolated urban or street flood events providing a demonstration of potential flood activity.

The probability of future occurrence for flooding on the CSU San Marcos campus is **Unlikely**.

Vulnerability to the Hazard

The CSU San Marcos campus is subject to the effects of localized flooding resulting primarily from excessive precipitation and isolated strong storms. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of San Marcos due to overflow or damage to flood control systems. The flood control channels and drainage systems that surround the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the CSU San Marcos campus will vary depending on when the flood were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community may become trapped on campus depending on the level of flooding occurring on surface streets. However, in rare, region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

CSU San Marcos is in proximity to a variety of industrial and commercial facilities in the surrounding communities. When these facilities are inundated with flood water, the potential for chemical release exists presenting possible exposures to individuals from the campus community. These facilities additionally line many of the primary access routes in and out of the campus.

During low probability, severe flood events, campus buildings and infrastructure may be vulnerable to localized flooding reaching the university. Campus utilities and
communication capabilities might be impacted by flood waters rendering them disabled. A flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. Flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings in the areas of localized or isolated flooding.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $217,777,651. However, it is unlikely for flood to cause destructive losses to the entire campus.

**Vulnerability Assessment Conclusions**

While the campus is removed from designated flood zones, the primary vulnerabilities to flood on campus are people and assets exposed to localized flooding from overflow of campus creeks or large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods.

The potential for rare, but severe flooding on the campus and the surrounding area generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.
**Hazardous Materials**

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”\(^5^9\) Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health.\(^6^0\) Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards:** fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)

---

\(^{60}\) California Department of Industrial Relations. *Worker Safety and Health During Fire Cleanup.* Retrieved 04.18.2021 from: [https://www.dir.ca.gov/dosh/wildfire/Worker-Health-and-Safety-During-Fire-Cleanup.html](https://www.dir.ca.gov/dosh/wildfire/Worker-Health-and-Safety-During-Fire-Cleanup.html)
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness

**Natural-Technological Incidents (Natechs)**: During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. The planning committee indicates that chemicals are located in the science lab on campus, Mapping indicates two hazardous waste sites very near campus, and a chemical site, a rail line and a gas pipeline grouped about ½ mile from campus. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city of San Jose and Santa Clara County, and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

For the CSU – San Marcos planning committee, chemicals are managed in the campus science lab, and no chemical spills have taken place. Based on these factors, along with the close proximity of hazardous waste sites and the other hazmat infrastructure within ½ mile, the extent of the hazard for the CSU – San Marcos campus is Low to Moderate. That said, it is prudent to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the

---

Loma Prieta Earthquake alone. 64 That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located. 65

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

For more details on specific hazmat events, please refer to the local, county and/or multi-jurisdictional hazard mitigation plans where CSU campuses are located at: https://www.caloes.ca.gov/cal-oes-divisions/hazard-mitigation/hazard-mitigation-planning/local-hazard-mitigation-program

According to the campus planning committee, no hazmat events have taken place on the CSU San Marcos on campus.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also to some degree apply to the students, staff and environment on the CSU – San Marcos campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – San Marcos) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

---

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the CSU – San Marcos campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low - the campus has experienced no chemical spills in the science lab. In addition, hazardous materials are in close proximity which may increase vulnerability and the probability of a campus-related event. Moreover, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of material or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the CSU – San Marcos campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus chemicals are located in the science lab on campus, Mapping indicates two hazardous waste sites very near campus, and a chemical site, a rail line and a gas pipeline grouped about ½ mile from campus. Due to their somewhat close proximity, gases and chemicals or hazardous waste, if spilled or released, could impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – San Marcos leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.
Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – San Marcos) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the San Diego County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – San Marcos campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – San Marcos planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure.\(^{67}\) These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow.\(^{68}\) These landslides may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high

---

earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 24-13. Based on the Figure below, the CSU-San Marcos campus is connected to areas with low to moderate susceptibility to landslide.

Figure 24-12: Deep-Seated Landslide Susceptibility Surrounding CSU-San Marcos

![Deep Seated Landslide Susceptibility Surrounding CSU San Marcos](https://maps.conservation.ca.gov/cgs/lsi/app/)

Extent of the Hazard

Landslide risk in San Diego is concentrated along canyons near the coastal areas with steep slopes. Landslides also occur throughout the western portion of the County and in the mountains to the east. Mitigation measures have stabilized many but not all landslides in urban areas. The indirect impacts of landslides in the region may cover a larger geographical extent than that of direct impacts. Based on the campus’ close proximity to the landslide hazard zone, and the history of significant impacts in the San Diego county, the planning committee ranks the extent of the landslide hazard for the campus as Moderate.

History of the Hazard

FEMA has declared twelve major disasters involving landslides, mudslides, mud flows, or debris flows since 1978 in San Diego County. NOAA recorded twenty-nine debris flow events from 2003 to 2019. No landslides have occurred on or immediately adjacent to the campus.

Potential Impacts of the Hazard

CSU San Marcos may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually. Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in San Diego County and therefore are highly likely to occur in the future. Given the location of the campus adjacent to the landslide zone, and the occasional occurrence of severe landslides in the county, the planning committee ranks the probability of the landslide hazard in some way impacting the campus as Possible.
Vulnerability to the Hazard

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. Based on the map provided, the campus might exhibit building and infrastructure vulnerabilities to some degree. Transportation routes surrounding the campus are vulnerable. See the landslide location map in relation to the campus along with landslide severity zones identified.

Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU San Marcos.

Vulnerability Assessment Conclusions

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the CSU San Marcos campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.

Power Outage

Description of the Hazard

San Marcos, CA is located in northern San Diego County, and spans across approximately 24 square miles.

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or
distribution of these commodities can leave populated areas like San Marcos, without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires, and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the CSU San Marcos campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of CSU San Marcos student residents in on-campus housing would also be affected by a power outage on campus and in the area.

Additionally, a severe outage to San Marcos would also directly affect the campus and the community. Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of **intentional** disruptions are:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.
Location of the Hazard

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of “stage alerts” to the media based on system conditions. The alerts are as follows:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard

Cal State San Marcos State has reported experiencing power outage events. PSPS outages impacted student housing interrupting everyday operations at resident halls and the use of electricity for scholastic and everyday needs while at the dorms. Two years ago, a west coast power outage prompted a campus shutdown, and, in the same year, a power pole car incident caused a small power outage.

Potential Impacts of the Hazard

Instructors, campus residents, staff and administration rely on electricity to maintain ongoing operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, enabling students with disabilities to enter, navigate and leave University buildings and long-term outages can potentially put students, faculty and staff safety at risk. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions and losing power can potentially lead to tragic results.

Climate Change and Energy Shortage
Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. San Marcos and San Diego County experience such outages. As such, the probability ranking for the San Marcos area is **Likely**. Since CSU San Marcos campus has also recorded power outage events, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the probability of future occurrences prompting intentional outages and creating unintentional power outages the hazard is high for the county in different areas but not specifically influencing the CSU San Marcos. Nonetheless, as discussed, campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate and cope with an interruption to electrical power.
Estimate of Potential Losses

Although the economic impact of power outage damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU-San Marcos.

Vulnerability Assessment Conclusions

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at CSU San Marcos. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

CSU San Marcos did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.

Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely

abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU San Marcos or San Diego County is within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While CSU San Marcos does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU San Marcos is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy.

---

enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU San Marcos.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

**Probability of Future Occurrence of the Hazard**

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked as **Unlikely**.

**Vulnerability to the Hazard**

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU San Marcos, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

**Estimate of Potential Losses**

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

**Vulnerability Assessment Conclusions**

CSU San Marcos is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

**Identified Data Limitations**
Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.
**Wildfire**

**Description of the Hazard**

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire

---

72 *State of California Hazard Mitigation Plan*, September 2018
behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests, and other lands with high susceptibility to fire occurring throughout the state. CSU San Marcos is located at the base of the San Elijo and San Marcos Hills. Areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur to the east and south of the campus. Additionally, these fire hazard zones exist in other areas throughout San Diego County. These areas of higher fire hazards occur extensively in suburban and rural areas of the northern and eastern areas of the county. Each of these hazard zones include moderate to heavy vegetation and are bordered by residential development.

The CSU San Marcos campus is located in northern San Diego County west of Escondido. The area immediately to the south and east of the campus is open hillsides with light to moderate vegetation. These areas of higher fire hazard border the campus in closest proximity to the Children’s Center, University Services Building, Social and Behavioral Sciences Building, the Arts Building, and Markstein Hall. The areas to the west are residential neighborhoods and areas to the north include commercial land uses. Fire Hazard Severity Zones are found on the western portions of the campus and throughout the hillsides surrounding the campus to include Very High Fire Hazard Severity Zones (VHFHSZ).
Fire Hazards Zones surrounding San Diego County and in proximity to the campus demonstrate the broader community threat that wildfires present to the population. Fire hazard severity zones are found surrounding the populated areas of the county. This presents the potential for fire related damages and smoke inundation to occur in many areas that members of the campus community reside at, are employed in, or where they recreate. Transportation routes are equally impacted causing potential added challenges for the campus community to get to areas if safety, get resources, or gain access to the campus.

Extent of the Hazard

The area immediately surrounding the CSU San Marcos campus is in direct proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does have a history of wildfire activity occurring within direct proximity to the campus. Additionally, the campus has experienced the effects of large wildfires occurring elsewhere in San Diego County. The campus closed due to fires in 2007, 2014, and 2017. Given the above factors, the planning committee ranks the extent of the hazard as **High**.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily
understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 24-24: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel -- especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 4: Very High Danger (VH)</td>
<td>Fires start very easily and spread at a very fast rate</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is</td>
</tr>
<tr>
<td>COLOR CODE: Orange</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Classification:

CLASS 5: Extreme (E)
COLOR CODE: Red

Fire situation is explosive and can result in extensive property damage.

Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. San Diego County also has a long history of wildfire activity primarily in the foothills and mountains. Wildfires occurring in the San Diego County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damages.

The area immediately surrounding the CSU San Marcos campus is in direct proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does have a history of wildfire activity occurring within direct proximity to the campus. Additionally, the campus has experienced the effects of large wildfires occurring elsewhere in San Diego County. The campus closed due to fires in 2007, 2014, and 2017. The County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The San Diego campus has experienced days of poor air quality due to fires burning in parts of the county, although infrequent.

Potential Impacts of the Hazard

The location of the CSU San Marcos campus surrounded by areas designated as High or Very High Fire Hazard Severity Zones places a threat of flame, ember, and smoke exposure from wildfire to the campus. There is potential for fire to occur on two sides of the campus and in the surrounding hillsides composed of light to moderate fuels. The threat of these neighboring hillsides to campus structures is substantial.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction of damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Threat to Central Plant
- Damaged or disrupted transportation, lifelines, and supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Potential for community wide evacuation
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Threat to Children’s Center
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations

77 San Diego County Multi-Jurisdictional Hazard Mitigation Plan, October 2017
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor staff work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of San Diego County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the wildfire threat potential in the area surrounding the CSU San Marcos campus the hillsides east and south of the campus, including the immediate proximity to Local Fire Hazard Severity Zones listed as “Very High”, the density of residential and commercial development, and the historic occurrences of fires, the probability of wildfire related damage is considered Possible.

Based on the wildfire threat potential in the area surrounding Southern California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered Possible.

Vulnerability to the Hazard

The CSU San Marcos campus is subject to direct impact from wildfire due to the campus location within a wildland-urban interface zone. The campus is identified to reside near a designated local High Fire Hazard Severity Zone. The campus is surrounded on by hillsides and open lands containing combustible vegetation combined with residential development. Additionally, vulnerabilities to the effects of wildfire would lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people.
These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillsides and extending onto the campus or localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have significant impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures. Structures with vegetation and other combustibles near the structure increases the ability of fire to spread to buildings.

Access to the south using Twin Oaks Valley Road servicing access to San Elijo and Carlsbad could become cutoff during fire incidents. Routes to the west and north are primary roadways servicing the greater community that would unlikely be impacted by fire. Access for supplies, equipment, and emergency services in addition to evacuation away from the campus would likely be forced to use northern routes into San Marcos or west to the coast. The campus community residing in areas to the east and south may find difficulty in gaining access to the campus or returning home from the campus in fire incidents in these areas.

Additional concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the northern San Diego County area even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU San Marcos students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU San Marcos campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human
vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $217,777,651. However due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in San Diego County, including wildfire incidents that have threatened or caused damages near the CSU Channel Islands campus. The location of the CSU San Marcos campus surrounded by open hillsides with light to moderate vegetative fuels along the entire eastern and southern edges presents a threat of fire to the campus community and campus assets. The foothills and mountains surrounding San Diego County host environments that are ideal for the development of wildfire activity. The consequences of fires in these areas would present primary and secondary consequences to the CSU San Marcos campus and expose vulnerabilities on the campus and to the campus community.
The topography of the valley surrounded by mountains allows for smoke filled air to linger in the valleys of Ventura County area with the potential for unhealthy air quality depending on wind conditions. Fires in the watersheds of the San Diego County Mountain ranges and tributaries may damage vegetation stabilizing hillsides and result in increased sediments to be discharged into the river system and reservoirs reducing their capacity and effectiveness. Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs and lack of a complete inventory of building construction types to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, Lightning)**

**Description of the Hazard**

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail,
lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both

the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU San Marcos.

**Regional Climate Influences on Severe Weather across California**

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.85

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU San Marcos), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.86

**Types of Storms in California**

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.87 The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.88 These storms affect (in varying degrees) all CSU campuses, including CSU San Marcos.

86 Retrieved on 07.17.2021 from [https://wrcc.dri.edu/Climate/narrative_ca.php](https://wrcc.dri.edu/Climate/narrative_ca.php)
- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\(^{89}\) Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.\(^{90}\) Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\(^{91}\) **Severe thunderstorms** are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\(^{92} \)\(^{93}\)

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.\(^{94}\)

- **Wind storm**: marked by high wind with little or no precipitation.\(^{95}\)

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\(^{96}\)

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.\(^{97}\)

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick

to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.98

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.99

### Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning

This hazard profile concentrates on the following types of severe weather hazards: **wind hazards (including tornadoes)**, **hail**, and **lightning**. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

#### Wind Hazards

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.100 Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” 101

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU San Marcos).

#### High Winds, Strong Winds, and Thunderstorm Winds

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

---

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.102

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.103

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.104

Please note: Straight-line wind is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.105 However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

Tornadoes

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.106 This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.107 On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.108

Santa Ana Winds. A type of wind hazard that is peculiar to Southern California is called a Santa Ana Wind. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern

---

106 Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/
108 Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions
Baja California (Mexico). They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape. (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.\(^{112}\)

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and

---

\(^{111}\) Retrieved on 07.14.2021 from [https://twitter.com/nwslosangeles/status/933049473034579968](https://twitter.com/nwslosangeles/status/933049473034579968)

\(^{112}\) Retrieved on 07.13.2021 from [https://www.fireweather.org/diablo-winds](https://www.fireweather.org/diablo-winds)
coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force (39-54 miles per hour) or higher, and can even reach hurricane force (≥74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.113 114 115

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.116 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.117

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.118

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.119 Lightning that is produced

---

from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including either at the CSU San Marcos main campus or at satellite campus facilities owned by the school. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all CSU San Marcos campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU San Marcos campuses reflect those of the surrounding community and County. As a result, all assets and people at CSU San Marcos campuses are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the San Marcos (San Diego County) and Temecula (Riverside County) areas, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MEDIUM**.
**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{123}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 24-28: Fujita Tornado Scale (Pre-February 2007)\(^{124}\)

F4  | Devastating tornado  | 207-260 mph  | Well-constructed houses leveled; structures with weak foundations blown off some distance; cars thrown and large missiles generated.  
F5  | Incredible tornado   | 261-318 mph  | Strong frame houses lifted off foundations and carried considerable distances to disintegrate; automobile sized missiles fly through the air in excess of 100 meters; trees debarked; steel reinforced concrete structures badly damaged.  
F6  | Inconceivable tornado| 319-379 mph  | These winds are very unlikely. The small area of damage they might produce would probably not be recognizable along with the mess produced by F4 and F5 wind that would surround the F6 winds. Missiles, such as cars and refrigerators would do serious secondary damage that could not be directly identified as F6 damage. If this level is ever achieved, evidence for it might only be found in some manner of ground swirl pattern, for it may never be identifiable through engineering studies.

Table below illustrates the Enhanced Fujita (EF) Scale, currently in use. Tornadoes that have occurred since February, 2007 are classified using the Enhanced Fujita Scale.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms. That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light, medium, or heavy* according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;
- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;
- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

**History of the Hazard**

Severe weather hazards have been an annual occurrence in San Diego County and on the CSU San Marcos main campus. Severe weather hazards have also been an annual

---

129 Retrieved on 07.15.2021 from [https://www.weather.gov/safety/thunderstorm](https://www.weather.gov/safety/thunderstorm)

occurrence in Riverside County and on the CSU San Marcos – Palm Desert campus. Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type. For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events. To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**San Diego County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in San Diego County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind:** at least 434 events, or approximately 17.13 events per year

---

139 National Climatic Data Center. Storm Events Database. Retrieved 07.30.2021 from [https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yy=1996&endDate_mm=04&endDate_dd=30&endDate_yy=2021&county=SAN%2BDIEGO%3A73&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA](https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yy=1996&endDate_mm=04&endDate_dd=30&endDate_yy=2021&county=SAN%2BDIEGO%3A73&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA)
- **Strong Wind**: at least 61 events, or 2.41 events per year\(^\text{140}\)
- **Thunderstorm Wind**: at least 88 events, or approximately 3.47 events per year\(^\text{141}\)
- **All Wind Hazard events** (excluding Tornadoes): at least 577 events, or approximately 22.78 events per year.\(^\text{142} \, 143\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in San Diego County, there have been at least 577 wind hazard events since 1996, excluding tornadoes.\(^\text{144} \, 145\) That translates to an approximate average historical frequency of **22.78** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 583 events) and simultaneous Database searches of all severe weather hazard events (i.e., 577 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as "Thunderstorm Wind" or "Hail" that are reported for San Diego County have actually taken place hundreds of times.

miles away, but are erroneously recorded as events that have occurred in the County. When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 577 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for San Diego County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that San Diego County has experienced since 1996 have been costly. There have been 7 deaths and 29 injuries, and property and crop damage estimates have totaled approximately $44,415,000 and $36,745,000, respectively.

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 13 reported events of tornadoes in San Diego County, which translates to approximately 0.51 tornado events per year.

The vast majority of tornado reports in San Diego County since 1996 have been of tornadoes with a severity rating of F0/EF0. Only two (2) of the tornadoes reported have been rated F1/EF1 or higher; both have been F1/EF1 tornadoes. That means that approximately 0.08 F1/EF1 tornado hazard events have occurred per year in San Diego County.

24-124
- **Thunderstorm Wind**: at least 114 events, or approximately 4.50 events per year\(^{166}\)

- **All Wind Hazard events** (excluding Tornadoes): at least 638 events, or approximately 25.18 events per year.\(^{167,168}\)

(Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Riverside County, there have been at least 638 wind hazard events since 1996, excluding tornadoes.\(^{169,170}\) That translates to an approximate average historical frequency of occurrence of 25.18 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 644 events) and simultaneous Database searches of all severe weather hazard events (i.e., 638 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Riverside County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{171}\)

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 638 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical Wind Hazard Losses for Riverside County since 1996

According to the NCEI Storm Events Database, the wind hazard events that Riverside County has experienced since 1996 have been costly. There have been three (3) deaths and 40 injuries, and property and crop damage estimates have totaled approximately $62,933,000 and $65,000, respectively.172 173

Tornado Wind Hazards

Information from the NCEI Storm Events Database indicates that since 1996, there have been 18 reported events of tornadoes in Riverside County, which translates to approximately 0.71 tornado events per year.174 While the vast majority of tornado reports in Riverside County since 1996 have been of tornadoes with a severity rating of F0/EF0, there have been (3) F1/EF1 tornadoes and one (1) EF2 tornado also reported.175

Historical Tornado Hazard Losses for Riverside County since 1996

According to the NCEI Storm Events Database, the tornado hazard events that Riverside County has experienced since 1996 have been costly. While there have been no deaths or crop damages reported, there have been three (3) injuries, and property damage estimates have totaled approximately $21,486,000.176

Hail

County severe weather hazard events recorded on the Storm Events Database, 75% of all deaths, 78.4% of all injuries, 74.9% of all estimated property damages, and 86.6% of all estimated crop damages have been attributed to wind hazard events alone.

Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April. From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

**Diablo Winds**

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.¹⁹¹

---

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{192}

Figure 24-18: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\textsuperscript{193}

\textit{Sundowner Winds}

Strong sundowner wind events occur approximately \textit{2-3 times per year}. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\textsuperscript{194}

\textbf{Historical Frequency of All Severe Weather Hazards}

Table below shows the average historical frequency of severe weather hazard events for San Diego County since 1996.

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within CSU San Marcos main campus and satellite campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU San Marcos campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

**CSU San Marcos Main Campus, San Marcos (San Diego County)**

The 2017 San Diego County Multi-Jurisdictional Hazard Mitigation Plan profiles only one severe weather-related hazard – coastal storm/coastal erosion/tsunami hazard. High winds are a component of this hazard. Damage from high wind speeds by themselves is considered to be minor, although they contribute to storm surge and erosion. As a result, wind hazards (including tornadoes) are considered to be of low to moderate significance, and therefore to have a minimal to moderate potential impact on the County and on the CSU San Marcos main campus. Tornadoes are not profiled at all by the Plan. As a result,
tornado hazards are considered to be of low significance, and therefore to have minimal potential impact on the County and on the CSU San Marcos main campus.195

**CSU San Marcos – Temecula Campus, (Riverside County)**

According to the 2018 County of Riverside Multi-Jurisdictional Local Hazard Mitigation Plan, wind hazards (excluding tornadoes) are considered to have a moderate to high potential impact, and tornadoes are considered to have a moderate potential impact, on Riverside County and (by extension) the CSU San Marcos – Temecula campus.196

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

**CSU San Marcos Main Campus, San Marcos (San Diego County)**

The 2017 San Diego County Multi-Jurisdictional Hazard Mitigation Plan profiles only one severe weather-related hazard – coastal storm/coastal erosion/tsunami hazard. Hail hazards are not profiled in the Plan. As a result, hail hazards are considered to be of low significance, and therefore to have a minimal potential impact on the County and on the CSU San Marcos main campus.197

**CSU San Marcos – Temecula Campus, (Riverside County)**

The 2018 County of Riverside Multi-Jurisdictional Local Hazard Mitigation Plan does not include the hail hazard as significant enough to profile; as a result, the hail hazard is considered to have a minimal potential impact on Riverside County and (by extension) the CSU San Marcos – Temecula campus.198

**Lightning**

Lightning strikes the United States about 20-25 million times a year.199 Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and

hundreds more have been injured.\textsuperscript{200} Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.\textsuperscript{201} (Commercial claim payouts for lightning losses for the U.S. were not available.)

**CSU San Marcos Main Campus, San Marcos (San Diego County)**

The 2017 San Diego County Multi-Jurisdictional Hazard Mitigation Plan profiles only one severe weather-related hazard – coastal storm/coastal erosion/tsunami hazard. Lightning hazards are not profiled in the Plan. As a result, lightning hazards are considered to be of low significance, and therefore to have a minimal potential impact on the County and on the CSU San Marcos main campus.\textsuperscript{202}

**CSU San Marcos – Temecula Campus, (Riverside County)**

The 2018 County of Riverside Multi-Jurisdictional Local Hazard Mitigation Plan does not include the lightning hazard as significant enough to profile; as a result, the lightning hazard is considered to have a minimal potential impact on Riverside County and (by extension) the CSU San Marcos – Temecula campus.\textsuperscript{203}

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year. Future occurrences of such events are projected to increase in both their frequency and intensity.

**CSU San Marcos Main Campus, San Marcos (San Diego County)**

The 2017 San Diego County Multi-Jurisdictional Hazard Mitigation Plan states that damage from high wind speeds by themselves is considered to be minor, although they do contribute to storm surge and erosion.\textsuperscript{204} However, according to the NCEI Storm Events Database, wind, hail, and lightning events occur on average far more than once per year, with wind hazard events occurring on average 22.78 per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU San Marcos main campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level.

\textsuperscript{201} Retrieved on 07.21.2021 from https://www.iii.org/table-archive/20504
level, it is assumed that the severe weather probabilities for the CSU San Marcos main campus reflect those of the surrounding community and County.

Based on the data available from both 2017 San Diego County Multi-Jurisdictional Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU San Marcos main campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU San Marcos is HIGHLY LIKELY.

**CSU San Marcos – Temecula Campus, (Riverside County)**

The 2018 County of Riverside Multi-Jurisdictional Local Hazard Mitigation Plan states that there is a moderate possibility that high wind hazard events will occur in the County occasionally (i.e., once every 5 years) in the future. However, according to the NCEI Storm Events Database, severe weather wind hazards have occurred in Riverside County far more than once annually – at an average of 25.18 events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU San Marcos – Temecula campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for CSU San Marcos – Temecula reflect those of the surrounding community and County identified in the Table below.

Taking into account the data available from both 2018 County of Riverside Multi-Jurisdictional Local Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU San Marcos – Temecula campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for the CSU San Marcos – Temecula campus is HIGHLY LIKELY.

**CSU San Marcos – All Campus Areas**

The probability of future occurrence of the severe weather hazard for all CSU San Marcos campus areas is HIGHLY LIKELY.

The following tables show the probabilities of future occurrence for component severe weather hazards for CSU San Marcos campuses in San Diego County and Riverside County.

---

Vulnerability to the Hazard

People, structures, and assets on the CSU San Marcos campuses are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. CSU San Marcos also has vehicles that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the both CSU San Marcos campuses. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within all CSU San Marcos campus areas are at risk from severe weather. There are approximately 35 buildings that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $217,777,651 for 25 buildings, and are unknown for the remaining 10
buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at CSU San Marcos varies throughout the day. As of Fall, 2019, CSU San Marcos had 14,519 students and 1,687 faculty and staff. All are at risk from severe weather events, with 16,206 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to all CSU San Marcos campus areas. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU San Marcos.

It is evident that CSU San Marcos has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.

24.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU San Marcos campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more
detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”

Table 24-36: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
</table>
| Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning? | ▪ Disabled students  
▪ Students in out-of-service areas  
▪ Students in or ageing out of foster care  
▪ Students from migrant worker families  
▪ Other small groups |
| Which population groups are most difficult to reach in an event?          | None                                                  |
| Which population groups have little/limited support networks if impacted by an event? | International students |
Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Meet with LGBTQI groups annually to review processes, emergency procedures, and discuss their vulnerabilities. Look at the issues of them being targeted in their spaces and what to do if there if there is a locked down.
- In addition to the university food pantry, a church near campus has food pantry and there are lots of north county food banks.
- Have an annex in EOP for health, and the dept has safety talks about how they would assist in an event.
- Using GEOFENCING for communications so if someone comes on campus will get messaging – good for visitors.
- Actively working with the international program and students. The risk managers work hand in hand with international program students for protocols, blackboard, etc., and are providing presentations on emergency management and giving them informational kits.
- Work with student support center and policies for immigrants and give the same talk to DACA and dreamers as give to the international students. The center directors give emergency managers an invitation, so they go to dept, give presentations and supply emergency management kits.
- They have a sprinter transportation station, if evacuation is needed, and have contracts with bus companies to request buses to get commuters where they need to go. It was used in the 2014 fire. They have specific areas identified on campus for commuter pickups – refer to the area to come in and get picked up.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced
social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.
Table 27-38: CSU San Marcos *Highly Likely, Likely and Possible* Hazards

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.208 Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states. 209 Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering

---

community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.\textsuperscript{210}

\textit{Erosion}

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

\textit{Extreme Temps}

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical

care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme cases, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses,
and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 211

**Landslides**

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied buildings which makes it a function of structural vulnerability and therefore, indirect. The degree of vulnerability to landslides by an individual considered at high risk, or even the general populations, also depends on human behavior, including many of the traditional social factors that are difficult to measure such as situational awareness, prior knowledge of hazards, and decision-making capabilities.212

Landslides can result in primary lifeline failures through the loss of roads or power and communication lines. Transportation routes are often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods. Risk from landslide relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure,
such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity.\(^\text{213}\) Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.\(^\text{214}\)

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following:\(^\text{215}\) particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.\(^\text{216}\)

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, 

---

adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.217

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

25.1 University Profile

University History

Sonoma State College was established by the California State Legislature in 1960 to be part of the California State College system, with significant involvement of the faculty from San Francisco State University. Sonoma State later became part of the California State University system. In 1978, Sonoma State College became Sonoma State University when the school officially gained university status.

Sonoma State is designated as a Hispanic-Serving Institution (HSI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The president is supported by multiple committees; Structure and Functions, the Executive Committee, the Senate Diversity Subcommittee, and the Senate Standing Committee (Academic Planning, Educational Policies, Faculty Standards and Affairs and Student Affairs; along with their respective subcommittees). The Academic Senate and Senate Standing Committees operate in an advisory capacity.

University Mission

“Sonoma State is a regionally serving public university committed to educational access and excellence. Guided by our core values and driven by a commitment to the liberal arts and sciences, Sonoma State delivers high-quality education through innovative programs that leverage the economic, cultural, and natural resources of the North Bay.”

Sonoma State University outlines four strategic priorities in support of their goals. The priorities are directed towards students’ success, academic excellence, leadership cultivation and transformative impact.

University Location

Sonoma State occupies approximately 269 acres (109 ha) on the east side of the main suburban area of Rohnert Park. Directly adjacent to the main campus is Wolf’s Den Plaza, a frequent hangout and eating area for SSU students.

In addition to the main campus, the university also owns and operates two off-campus study sites for students of the natural sciences. The first site is the 411-acre
The second site is the 3,200-acre (1,300 ha) Galbreath Wildlands Preserve in Mendocino County.[26] Both offer opportunities for research and hands-on education to students of the university. Sonoma State also offers students the opportunity to obtain their bachelor’s degree in liberal arts partly through classes offered at Napa Valley College and the Vallejo Satellite Campus of Solano Community College.

University Population

In the fall of 2019, the enrollment of graduate and undergraduate students exceeded 8,600 students. White students make up 45.6% of the student population with Latino students making up 35% of the population. A majority of undergraduate students are first generation and full-time, and many are Pell Grant eligible.

25.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate.
Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

25.3 Hazard Identification and Risk Assessment

Overview of Sonoma State University History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 25-1 (following).

Table 25-1: Hazard Identification Determinations

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely** - 76%-100% that the hazard would occur annually.
- **Likely** - 50%-75% that the hazard would occur annually.
- **Possible** - 11%-49% that the hazard would occur each annually.
- **Unlikely** - 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent.¹ They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions.² The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.³

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)⁴

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table CD.1 below.)

**Descriptions of Identified Communicable Disease Hazards at Sonoma State University**

Sonoma State University (SSU) has identified three (3) communicable disease hazards that have had the greatest impact on campus – COVID, H1N1, Norovirus. The following are brief descriptions of the communicable disease hazards at SSU.

**COVID-19 (SARS-CoV-2)** Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.\(^5\)

**Influenza (Including sub-type H1N1/Swine Flu)**

Influenza is a viral infection that attacks the respiratory system (i.e., nose, throat, and lungs). Influenza viruses travel through the air in droplets when someone with the infection coughs, sneezes or talks. Influenza is transmitted either by inhaling virus-laden droplets directly, or by coming into physical contact with an object (e.g., telephone or computer keyboard) and then transferring the virus to the eyes, nose or mouth. People with the virus are likely contagious from about a day before symptoms appear until about five days after symptoms begin.

Common signs and symptoms of the flu include: fever, aching muscles, hills and sweats, headache, dry and persistent cough, shortness of breath, tiredness and weakness, runny or stuffy nose, sore throat, and eye pain. (Vomiting and diarrhea are also influenza signs and symptoms, but these are more common in children than in adults.)

Influenza viruses are constantly changing, with new strains appearing regularly. As a result, antibodies against influenza viruses that have been encountered in the past

may not offer protection from new influenza strains, as the new strains can be very
different viruses from previous strains.⁶

**H1N1 Flu (Swine Flu)**

The H1N1 flu, commonly known as swine flu, is a type of influenza A virus and is one
of several flu viruses strains that can cause the seasonal flu. It is primarily caused by
the H1N1 strain of the flu (influenza) virus. Symptoms of the H1N1 flu are the same as
those of the seasonal flu.

The H1N1 virus is a combination of viruses from pigs, birds and humans that causes
disease in humans. The virus enters your body when you inhale contaminated
droplets or transfer live virus from a contaminated surface to your eyes, nose or
mouth. It then infects the cells that line your nose, throat and lungs.⁷

**Norovirus**

Norovirus is a highly contagious virus commonly spread through food or water that is
contaminated by fecal material during food preparation or by contaminated surfaces.
Specifically, this virus can be transmitted through: consuming contaminated food,
drinking contaminated water, and touching one’s hand to one’s mouth after the hand
has been in contact with a contaminated surface or object.

Norovirus can also be transmitted through close contact with an infected person.

Norovirus infections occur most frequently in closed and crowded environments such
as hospitals, nursing homes, child care centers, schools and cruise ships. Noroviruses
are difficult to kill off because they can withstand hot and cold temperatures and most
disinfectants.

Symptoms such as diarrhea, stomach pain and vomiting typically begin 12 to 48 hours
after exposure, and usually last one to three days. Most people recover from
norovirus completely without treatment. However, for some people — especially
infants, older adults and people with underlying disease — vomiting and diarrhea can
be severely dehydrating and require medical attention.⁸

**Location of the Hazard**

Communicable diseases have the potential to affect the entire Sonoma State
University (SSU) planning area equally. As a result, the communicable disease hazard
can be found at the SSU main campus located in Rohnert Park, CA (Sonoma County).
Because of the ubiquitous nature of many communicable diseases, students, faculty,
staff at (and visitors to) SSU are at risk of exposure to the communicable disease

---

hazard.\(^9\) (Please note: SSU also offers upper-division BA degree completion programs in Liberal Studies at Mendocino College in Ukiah, CA (Mendocino County), Napa Valley College in Napa, CA (Napa County), and Solano Community College in Vallejo, CA (Solano County). However, SSU does not appear have ownership of any buildings on these campuses.)

**CSU Student Housing Locations and Populations**

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. Table 25-4 shows the number of students that were living in CSU-campus-owned housing in Fall, 2019, prior to the COVID-19 pandemic. For Sonoma State, approximately 37% of its 8,649 enrolled students (or 3,200 students) reside in student housing.\(^{10,11}\)

**Extent of the Hazard**

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 25-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

\(^9\) California State University. About CSU. Retrieved 04.30.2021 from: [https://www2.calstate.edu/csu-system/about-the-csu](https://www2.calstate.edu/csu-system/about-the-csu);

The Extent of Sonoma State University (SSU) Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of measles at CSU Channel Islands. Measles would be classified at the BSL-2 containment level.\textsuperscript{13}

The Extent of Sonoma State University (SSU) COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.\textsuperscript{14}

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 137 cases of COVID-19 at SSU. Most communicable disease data are maintained by at the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the

jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

The following tables (25-5 and 25-6) show both campus- and County-level COVID-19 Case data for Sonoma State (SSU). These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics have (and will continue to have) direct impact on life, health, and safety across the CSU system including the SSU campus. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of CSU campus populations contract communicable diseases at the same time and are therefore unable to perform

maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of SSU students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including SSU) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 25-6: WHO Risk Group Characterization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies</td>
</tr>
</tbody>
</table>

are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)

Table 25-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall into these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases that fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.
Table 25-7: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

| RG 3 | Anthrax  
West Nile Virus  
SARS Virus  
(Including COVID-19)  
Tuberculosis  
Typhus  
Yellow Fever  
Hantaviruses  
Avian Flu | These bacteria and viruses cause severe to fatal disease in humans, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone. |
|---|---|
| RG 4 | H5N1 (Bird Flu)  
Dengue Hemorrhagic Fever  
Marburg Virus  
Ebola Virus  
Smallpox  
Lassa Fever  
Crimean-Congo Hemorrhagic Fever  
Other Hemorrhagic Diseases | These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are *not* available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release. |
Probability of Future Occurrence of the Hazard

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency. Table 25-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 25-8: Likelihood of Future Hazard Occurrence

<table>

</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

**Vulnerability to the Hazard**

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the SSU campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, CSU – Sonoma had 8,649 students and additional faculty and
Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic on the SSU campus.

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU – Channel Islands) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

Economic Impact of COVID-19 Pandemic on CSU Financial Health

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 25-2 below for the economic impact to Sonoma State.) Several CSU campuses saw refund losses surpass $10 million. (See Figure 25-2.)

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 25-11) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

### Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. *If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time.* This scenario would likely overwhelm available on-campus medical services and could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 25-12 below for the “10% outbreak scenario” projections for the SSU campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system, including Sonoma State. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
Data regarding projected population changes;
Data regarding absenteeism; and
Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Dam and Levee Failure**

**Description of the Hazard**

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtopping to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

---

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

Sonoma County is home to flood control facilities and levee systems. The dam facilities are mostly along the base of the various mountains and hills throughout the county. Levees have been constructed along the San Francisco Bay and flood control channels providing community protection. The Sonoma State University campus is not in proximity to dams presenting a threat to the campus.

However, the Warm Springs Dam holding Lake Sonoma demonstrates an inundation area that extends from the lake through Santa Rosa and reaching the northern boundaries of Rohnert Park. The campus is shown to remain out of the inundation zone for Lake Sonoma. Lake Sonoma is located 32 miles north of the Sonoma State University campus west of Geyserville. There are a number of small dams in the eastern portion of Santa Rosa but these dams do not show an inundation extending beyond the City of Santa Rosa.
Lake Sonoma releases water into Dry Creek and later into the Russian River before reaching the Pacific Ocean. The Russian River travels in a south bound direction before turning to the west just north of Santa Rosa. The Sonoma State University campus is separated from the turn of the Russian River by 15 miles. The river is not lined with levees and the campus is not within a levee protected zone.
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- High hazard potential dams may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- Significant hazard potential dams are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
• Low hazard potential dams are not expected to result in loss of like, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

<td>Dry Creek</td>
<td>Warm Springs</td>
<td>449,000af</td>
<td>High Hazard</td>
</tr>
</tbody>
</table>

The Sonoma State University campus lies outside of the inundation zone of the dams listed above. In the unlikely event of a catastrophic failure of the identified dams, the Sonoma State University campus is expected to remain out of the inundation area. The inundation area is expected to spread water in areas to the north and west of the campus. The inundation zone extends to the northwest corner of Rohnert Park but does enter the city. Additionally, there are multiple transportation corridors that lie within the dam inundation zones that could compromise access, evacuation, and supply routes. The inundation areas have the potential to threaten areas in which the campus community resides or works. However, based on these conditions, the planning committee ranks the extent of the dam failure hazard as **Low**.

Extent – Levee Failure

There are no identified levees in proximity to the campus and thus the campus is not located within an area subject to flooding from levee failure. Based on no levee failure risk to the campus and no historical occurrences elsewhere in the larger community, the planning committee ranks the extent of this hazard is **Low**.

History of the Hazard

There are no records of dam or levee failures in areas that present a threat to the Sonoma State University campus. Sonoma County has no record of dam failures:

31 Sonoma County Hazard Mitigation Plan Update, April 2017
Potential Impacts of the Hazard

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

**Probability of Future Occurrence of the Hazard**

Sonoma County remains at risk from dam and levee failure. The facility most likely to impact campus operations is the Warm Springs Dam containing Lake Sonoma. The facility is located 32 miles north of the campus. However, the location of the Sonoma State University campus is located outside of identified dam inundation zone 2 miles to the east opposite of US Highway 101. There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on historical experience and occurrences, the likelihood of this hazard is low, and the probability of future occurrence for both dam and levee failures is **Unlikely**.

**Vulnerability to the Hazard**

Given high priority monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. As such, the campus’ vulnerability is tied to the consistency of these practices, and, therefore, is not considered to be truly vulnerable on a daily basis. However, in the unlikely event of a catastrophic failure, the effects of flooding from compromised dams and levees would likely mostly affect members of the campus community in terms of disruption to regional transportation networks and services and the amount of time to respond to the needs of the campus community prior to inundation would be limited.

Any breach along a dam is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in the vulnerability of numerous displaced individuals and households. The lack of flood insurance will cause extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the Sonoma State University campus will vary depending on when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are
at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs are $289,079,090. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at Sonoma State.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the Sonoma State University campus, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences would be catastrophic to downstream communities The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.
Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.
**Drought**

Hazard Description

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
Socioeconomic drought refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for SSU) versus water usage for wildfire abatement or natural resource protection.

Location of the Hazard

Drought conditions have been identified in Rohnert Park and Sonoma County, where SSU is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years. 32

Extent of the Hazard

Given the historical occurrence of drought impacts throughout the county and city surrounding the planning area, and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire CSU system-wide planning area equally, the extent of the hazard is variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. That said, the extent of the hazard on campus is reported to be Moderate due to a combination of prolonged drought periods and competition for water resources tied to an increase in development in the Sonoma region.

In addition, drought related land subsidence has occurred statewide and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Though these effects have not been

reported on campus, they remain issues of concern for the campus over the long term.

Although the campus planning team identifies the extent of the hazard as Moderate (qualitatively) which corresponds to D1 – D2 on the Extent scale (below), Sonoma County has experienced more severe drought conditions, including D4 levels during the statewide event from 2012-2017. As such, the campus planning team recognizes that while historic impacts shaping the extent of drought on campus have been minimal, the potential impacts are tied to trends across larger geographic areas, and, therefore, the committee recognizes that the extent of drought on campus has the potential to increase in the future.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

Table 25-14: Impacts of Drought Levels as Determined by US Drought Monitor

</tbody>
</table>

| Wine country tourism increases; lake- and river-based tourism declines; boat ramps close |
| Trees are stressed; plants increase reproductive mechanisms; wildlife diseases increase |
| Water temperature increases; programs to divert water to protect fish begin |
| River flows decrease; reservoir levels are low and banks are exposed |

| Livestock need expensive supplemental feed, cattle and horses are sold; little pasture remains, producers find it difficult to maintain organic meat requirements |
| Fruit trees bud early; producers begin irrigating in the winter |
| Federal water is not adequate to meet irrigation contracts; extracting supplemental groundwater is expensive |
| Dairy operations close |
| Marijuana growers illegally tap water out of rivers |
| Fire season lasts year-round; fires occur in typically wet parts of state; burn bans are implemented |
| Ski and rafting business is low, mountain communities suffer |
| Orchard removal and well drilling company business increase; panning for gold increases |
| Low river levels impede fish migration and cause lower survival rates |
| Wildlife encroach on developed areas; little native food and water is available for bears, which hibernate less |
| Water sanitation is a concern, reservoir levels drop significantly, surface water is nearly dry, flows are very low; water theft occurs |
| Wells and aquifer levels decrease; homeowners drill new wells |
| Water conservation rebate programs increase; water use restrictions are implemented; water transfers increase |
| Water is inadequate for agriculture, wildlife, and urban needs; reservoirs are extremely low; hydropower is restricted |

| Fields are left fallow; orchards are removed; vegetable yields are low; honey harvest is small |
| Fire season is very costly; number of fires and area burned are extensive |
| Many recreational activities are affected |
| Fish rescue and relocation begins; pine beetle infestation occurs; forest mortality is high; wetlands dry up; survival of native plants and |
animals is low; fewer wildflowers bloom; wildlife death is widespread; algae blooms appear

Policy change; agriculture unemployment is high, food aid is needed

Poor air quality affects health; greenhouse gas emissions increase as hydropower production decreases; West Nile Virus outbreaks rise

Water shortages are widespread; surface water is depleted; federal irrigation water deliveries are extremely low; junior water rights are curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor;

History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous. According to the US Drought Monitor, Time Series data, Sonoma County (including the CSU – Sonoma footprint) has experienced 6 periods of drought covering 10 of the last 21 years (2000 – 2021), including the statewide event from 2012-2017.

Figure 25-5: Periods of Drought in Sonoma County, California, 2000 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as

separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.  

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the CSU – Sonoma campus planning area:

Note: On campus, drought impacts to flora and landscaping have been reported by the campus planning committee.

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring

food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent. 37

Potential Impacts of the Hazard

On campus, drought impacts to flora and landscaping have been reported by the campus planning committee. Drought impacts statewide are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic impacts of drought throughout the city and county surrounding the planning area are a sub-set of larger and inter-connected regional droughts, and provide a sound basis for understanding potential (future) impacts on campus.

The most significant potential impact associated with drought across the campus planning area is a potential reduction in water availability for the municipal area tied to the campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of SSU to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of any agricultural research crops and/or field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. 38 However, the wildfire hazard is analyzed separately in this plan. See section below for coverage of the wildfire hazard.

In reviewing the occurrences of drought for Sonoma County, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to campus, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted

within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.39

At present, drought related damage to campus buildings and infrastructure at Sonoma State has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for SSU is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Probability of Future Occurrence of the Hazard

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that SSU lies within a drought impacted region, it is

---

prudent to extend the Highly Likely probability of occurrence to the planning area
even though past occurrences and impacts on campus have been minimal.

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest
elevation at which snow falls, reducing water storage in the snowpack, particularly at
those lower mountain elevations which are now on the margins of reliable snowpack
accumulation. Higher spring temperatures will also result in earlier melting of the
snowpack. The shift in snow melt to earlier in the season is critical for California’s
water supply because flood control rules require that water be allowed to flow
downstream and that water cannot be stored in reservoirs for use in the dry season.
As such, state-level drought risk factors that have led to drought’s state-wide severity
and extent, and potential impacts also create drought vulnerabilities at the level of the
CSU – Sonoma campus. Specifically, the campus planning committee reports that
although their source water wells are healthy currently, an increase in development in
the Sonoma region has created competition for water resources. In response, the
campus is seeking funding to connect to city water to create a source redundancy to
reduce its vulnerability.

Moreover, climate change will likely adversely impact the vulnerability of watersheds
and ecosystems in their ability to deliver important ecosystem services. These
changes may limit the natural capacity of healthy forests to capture water and
regulate stream flows. Sierra Nevada mountain winters and springs are warming, and
on average, precipitation as snowfall relative to rain is decreasing. A warming climate
with reduced snowpack will result in earlier snowmelt and will subsequently reduce
downstream water availability during summer and early fall.

As such, the state and the SSU planning area’s stakeholders potentially have less
capacity to address future drought risks due to projected temperature increases and
shortages in water; ground-water withdrawals have been occurring at a deficit rate of
1 – 2-million-acre feet per year, where the impacts of drought include decreased
availability of water for agriculture and environmental uses. 41 In forested and other
vegetated areas, prolonged drought decreases the moisture content of forest fuels
and increases the risk of high severity wildfires.

California is the single most productive agricultural state and its agricultural industry
relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly
variations in snowpack depths have implications for water availability as snowmelt
from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner
Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1

05.04.2021 from: https://frap.fire.ca.gov/data/assessment2010/pdfs/3.1water.pdf
snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir. 42

Vulnerability of Populations

The historical and potential impacts of drought on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the SSU campus over the long term.

Property Vulnerability

The historical and potential impacts of drought on property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the SSU campus over the long term.

Natural Environment Vulnerability

The core issue shaping drought vulnerability on campus and throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

Critical Facilities Vulnerabilities

Drought vulnerabilities for CSU – Sonoma’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence over the long term.

Estimate of Potential Losses

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City and county of Sonoma, and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

Vulnerability Assessment Conclusions

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

Identified Data Limitations

Data are limited concerning campus-related agricultural assets as well as data on campus tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

Fault Rupture – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

Liquefaction – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.
**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. Sonoma State University is located in the northern area of the San Francisco Bay region. In general, fault systems surround and traverse throughout the Bay Area and Sonoma County including the area of Sonoma State University. Throughout the populated areas of Sonoma County and surrounding cities, the ground is saturated with sediment eroded from the hills by means of multiple stream channels. Liquefaction zones rated at moderate susceptibility exist on all sides of the campus.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 19 miles west of the Sonoma State University campus. In addition to the San Andreas Fault, Sonoma County is home to or near additional fault systems with the potential to generate strong ground shaking. The campus is additionally in close proximity to two fault systems. The Rodgers Creek Fault traverses south to north along the eastern side of the Santa Rosa Valley less than 3 miles east of the Sonoma State University campus. The Bennett Valley Fault extends south to north 20 miles in length from Sonoma Valley to Santa Rosa 5 miles east of the Sonoma State University campus. The 27-mile long West Napa Fault connects Vallejo to St Helena 16 miles east of the campus. The entire San Francisco Bay Area is saturated with numerous additional faults mostly paralleling the San Andreas Fault to the northwest. These fault systems are located on each side of the campus.
The Sonoma State University campus resides on areas designated to be in liquefaction zones. All campus facilities are potentially located within a moderate liquefaction zone. The liquefaction zones generally appear along the western and eastern edges of Rohnert Park. Liquefaction zones additionally appear throughout much of the County along valley floors.

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude and intensity. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.
The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

Table 25-17: Modified Mercalli Intensity Scale

substantial buildings, with partial collapse. Buildings shifted off foundations.

Extreme

Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations. Rails bent.

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.
Based on the earthquake shaking potential in the Sonoma County area, the campus residing within a liquefaction zone, its proximity to eight fault systems and the extensive history of occurrence and severe impacts in the area, the extent of the earthquake risk is considered **Moderate to High**.

### History of the Hazard

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Likewise, Sonoma County also has a long history of earthquake activity. The entire area of Sonoma County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The April 18, 1906 San Francisco Earthquake became one of the most well-known earthquakes in California history. The earthquake caused extensive damage to buildings, bridges, water systems, and critical facilities. Damage was experienced well beyond San Francisco including areas such as Monterey and Santa Cruz. 3,000 people were killed and thousands more injured. The San Francisco Earthquake was found to shift the course of northern California rivers. The shaking was felt from Oregon to Los Angeles.

The October 17, 1989 Loma Prieta Earthquake shook a large part of northern California, especially the San Francisco Bay Area. The earthquake caused $5.9 billion in damages, most extensively in San Francisco, the East Bay, and South Bay areas. The earthquake resulted in extensive infrastructure damages, 12,000 displaced, 3,757 injuries, and 63 fatalities. The earthquake was provided a federal disaster declaration (DR-845).

**Potential Impacts of the Hazard**

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils on the campus and surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in Sonoma County area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Rohnert Park and Santa Rosa could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Sonoma County could result in extensive casualties, expansive
structure damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader northern San Francisco Bay region limiting immediate assistance that the campus may normally expect.

Local impacts to the Sonoma State University campus caused by an earthquake could include:

- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway and roadway system
- Compromised transportation routes for access, supplies, services, and evacuation
- Structural damage to bridges
- Damage to flood control and drainage system
- Environmental damage to waterways and streams
- Structural damage to levees
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Damage to on-campus utility infrastructure
- Damage to campus reclaimed water system and capability to support fire suppression system
- Release of airborne asbestos from damaged older buildings
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby apartment complexes and residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Sonoma County fault systems surrounding the North Bay region is included in the following table.

Table 25-19: Major Potentially Active Faults in Proximity to Sonoma State University

---

46 Sonoma County Hazard Mitigation Plan Update, April 2017
The Sonoma County Hazard Mitigation Plan Update describes the probability of an earthquake Magnitude of 6.7 or greater in the San Francisco Bay Area over the next 30 years is 72%. The Plan further demonstrates that these estimations are being updated continuously to address updated analyses. There is a 76% probability of one or more magnitude 7.0 earthquakes striking Northern California within 30 years beginning in 2014.48

Based on the earthquake shaking potential in the Sonoma County area, the proximity to the fault systems illustrated above, the probability of seismic ground shaking that would generate damage is considered **Possible**.

**Vulnerability to the Hazard**

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of Sonoma State University places the campus in a suburban community near residential, commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to the San Francisco Bay region generally surround the area and some cross near the Sonoma State University

---

48 California Earthquake Authority, California Earthquake Risk Map & Faults By County, [https://www.earthquakeauthority.com/California-Earthquake-Risk/Faults-By-County](https://www.earthquakeauthority.com/California-Earthquake-Risk/Faults-By-County)
campus. The campus resides in a region that is exposed to fault systems on all sides. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected.

Elements of the vulnerability to a major earthquake on the Sonoma State University campus will vary depending on when the earthquake were to strike. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. This may be heightened in the southwestern portions of the campus as this area has been identified as being within a liquefaction zone. As the Sonoma State University campus is downstream from dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

The San Francisco Bay Area and Rohnert Park in particular are moderately populated and attract commuter employees to the commercial cores. The road and freeway network becomes easily congested in normal situations. Sonoma County relies on US Highway 101 as a primary overland transportation route with minimal state highway alternatives. A major earthquake has the potential for rendering these critical lifelines and supply routes inoperable and forcing the campus community to be self-reliant for a period of time.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services,
require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $289,079,090.

**Vulnerability Assessment Conclusions**

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater San Francisco Bay region, the North Bay, and the Sonoma State University campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In
any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the Sonoma State University campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding Rohnert Park and Santa Rosa, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader San Francisco Bay region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population is additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.
Erosion

Description of the Hazard
The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another”. 49 Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable.

Location of the Hazard
Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. As such, for the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the Sonoma State University (SSU) campus with erosion-prone characteristics. That said, no specific sites on campus have been identified as at risk. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area.

Extent of the Hazard
There is no published scale of severity or extent for this geologic hazard. If conditions are favorable, erosion is likely to occur. Given no historical occurrence of erosion on campus nor any data identifying specific sites on campus at risk, the planning committee ranks the extent of this hazard as Low.

History of the Hazard
Copeland Creek has been monitored for erosion since 2011, and SSU has conducted and maintained several erosion mitigation projects along the length of the creek. However, no erosion has been identified on campus.

Potential Impacts of the Hazard
Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

Erosion of soil also results in the loss of fertile land, increased pollution and sedimentation in water ways, and can worsen flooding. At Sonoma State’s Fairfield Osborn Center, soil erosion can create concerns for research and natural resource management.

**Probability of Future Occurrence of the Hazard**

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, the probability of future occurrence is high. That said, with regard to the SSU campus, given the lack of historical events or existing conditions favorable to erosion, the probability of future occurrence is Low. However, conditions could emerge in the future which increase the probability, precipitated by climate change, changes in land-use or other factors.

**Vulnerability to the Hazard**

Topography, soil structure, land use, and precipitation are all factors of erosion. Sonoma State’s infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. CSU leadership should consider performing an analysis to identify such at-risk buildings, infrastructure, slopes and soil types in the future.

In the wider Sonoma community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

**Vulnerability Assessment Conclusion**

While the ability to predict future erosion on the SSU campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
Extreme Temperatures (Includes Extreme Cold and Extreme Heat)

Heat

Description of the Hazard

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.50

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.51 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperature “feels” hotter. The combination of temperature and humidity is known as the heat index.52

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.53 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.54

Location of the Hazard

Extreme heat events are a non-spatial hazard and may occur throughout the Sonoma State campus.

Extent of the Hazard

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the high 70s to the low 80s in the City of Rohnert Park. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded in Sonoma County was 112° F on June 14, 2000. This temperature was

52 Ibid.
reached during a historic heat wave that affected much of the state of California, causing record-high temperatures.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria.\textsuperscript{55} In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 25-9 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

Figure 25-9: Methodology for Determining Heat Index

As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.

\textsuperscript{55} National Weather Service. Heat. Retrieved 01.29.21 from: https://www.weather.gov/bgm/heat

History of the Hazard

Data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database show that there have only been four heat events that have affected Sonoma County since 1950, and that there have been no excessive heat events.

Potential Impacts of the Hazard

During an excessive heat event, Sonoma State may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

As the City of Rohnert Park (where the main Sonoma State campus is located) has had no excessive heat events in the past 70 years, it is unlikely that the hazard will occur

---

annually. The City of Rohnert Park, excluded excessive heat as a profiled hazard in its 2018 Local Hazard Mitigation Plan, but concluded that it might be a risk in the future.57

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.58 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. All that said, due to the infrequency of extreme heat and the mild average daily temperatures from June to October ranging from the 70’s to the 80’s, the campus’ vulnerability to this hazard is minimal.

Similar to the City of Rohnert Park, Sonoma State excludes the hazard of extreme heat in its Emergency Plan, instead choosing to address other forms of extreme weather such as floods, high winds, and severe winter storms.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

It is difficult to predict the likelihood of future heat events at the Sonoma State campus, however, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Northern California has warmed about 1 – 1.5 degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.59

Cold

Description of the Hazard

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.60

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.61 This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underlying tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes.62 It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases.63 The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6° F. Hypothermia occurs when your body temperature falls below 95° F.64 As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

63 Ibid.
Location of the Hazard

Extreme cold events are a non-spatial hazard, and may occur throughout the Sonoma State campus.

Extent of the Hazard

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in the City of Rohnert Park typically range from the high 30s to low 40s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in Sonoma County was 13° F on December 22, 1990.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30° F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.65

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure 25-10 (following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow). Given the historical and potential occurrence of freezing temperatures, but a low probability of extreme cold, the planning committee ranks the extent of the hazard as Low to Moderate.

In 2011, the National Weather Service introduced an experimental program that issued warnings for extreme cold events, independent of other severe weather warnings. The test areas included North and South Dakota and Minnesota. However, in 2012, after a single season of use, the program was abandoned, based on reports of confusion among test audiences.66

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, Sonoma County has had six frost/freeze events, as well as two extreme cold/wind events on January 16, 2013 and April 8, 2017. [Records for this hazard were first recorded in 1996].

Potential Impacts of the Hazard

Should an extreme cold event occur, Sonoma State might experience impacts due to cancelled classes.

---

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

Probability of Future Occurrence of the Hazard

Sonoma County has experienced 6 freeze/frost events as well as 2 extreme cold/wind events since 1996, or approximately one event every three years. It is therefore possible that this hazard may occur annually.

Vulnerability to the Hazard

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more likely to suffer illness or death as a result. Sonoma State addresses the potential for frost/freeze and high wind events in its campus Emergency Plan. The most likely cause of cold weather for the campus would be a severe winter storm with high winds and rain, which can cause flooding, extended power outages, and road closures. The campus regularly monitors weather conditions in order to prepare before a storm hits. If conditions are dangerous, the campus will close and cancel classes.

Power outages are also a concern for the university. The university is on the main power grid and power is supplied by Pacific Gas & Electric (PG&E). A number of facilities are equipped with back-up generators that can allow for partial function.

68 Sonoma State University Emergency Plan. 11.7 Severe Weather and Environmental Flood. Retrieved 03.24.21 from http://emergency.sonoma.edu/planning-operations/emergency-plan#weather
during outages, but long-lasting outages may threaten the safety of well water for drinking as well as the use of telecommunication systems.\textsuperscript{69}

Although this may be a hazard that Sonoma State faces, the campus has plans in place to handle the risks and vulnerabilities.

**Estimate of Potential Losses**

Based on the previous historical occurrences of extreme heat events, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

**Vulnerability Assessment Conclusions**

While the ability to predict future extreme cold events at the Sonoma State campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), areas in Northern California have warmed approximately 1 – 1.5 degrees on average over the last century, with less rainfall. This may lead to fewer frost/freeze events in the future.\textsuperscript{70}

**Identified Data Limitations**

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

---

**Flood**

**Description of the Hazard**

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding represents one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater
amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric Rivers**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Location of the Hazard

Rohnert Park is located in Sonoma County on the north side of the San Francisco Bay area. Sonoma County can experience flooding from overflowing rivers and streams in addition to heavy precipitation events in low lying areas. These areas often experience shallow flooding impacting roadways and other areas where drainage is inadequate. The central portions of Sonoma County are within the Santa Rosa Plain where a series of creeks and rivers traverse in route to the Pacific Ocean. The communities in central Sonoma County are populated with extensive residential neighborhoods surrounded by open or agricultural fields. The campus is adjacent to both residential neighborhoods and agricultural fields.

71 National Oceanic and Atmospheric Administration, “What are atmospheric rivers?”, https://www.noaa.gov/stories/what-are-atmospheric-rivers
The Sonoma State University campus is located on the valley floor of the Santa Rosa Plain allowing for the flooding potential in low-lying areas. The campus has Copeland Creek traverse through the northern portions of the campus. There are a series of low rising hills 3 miles to the east of the campus providing drainage for precipitation events. The entire Sonoma State University campus sits within a Special Flood Hazard Area (SFHA) Zone X: Area of Minimal Flood Risk designation on the Flood Insurance Rate Map. The exception is the area that Copeland Creek traverses through the campus which is designated as Zone AE: 1% Annual Chance Flood Hazard.

Extent of the Hazard

The Sonoma State University campus is entirely located in a designated Zone X: Area of Minimal Flood Hazard. The access routes into and out of the campus servicing locations in all directions are also found in areas primarily designated as Zone X: Area of Minimal Flood Hazard. The campus has no history of flood events, though minor isolated ponding on campus has occurred during heavy rainfall events. Given that the area surrounding the Sonoma State University campus does not generally promote
conditions for flood waters to accumulate, the planning committee ranks the extent of the hazard on campus as **Low**. In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 25-21: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised maps in place on Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, base flood elevations derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
</tbody>
</table>
Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between one and three feet.

Areas with a 1% annual chance of flooding, where shallow flooding average depths are between one and three feet.

Represents areas between the limits of the 1% annual chance flooding and 0.2% annual chance flooding.

Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No Base Flood Elevation or depths are shown within this zone.

History of the Hazard
Flooding in Rohnert Park and the broader Sonoma County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and numerous fatalities. The following provides insight into information of past flooding events that are significant to the Sonoma State University campus.

Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source.

- Potential impacts resulting from flooding include:
  - Injuries or loss of life
  - Property destruction or damage
  - Loss of property contents
  - Infrastructure damage including roadways, bridges, other transportation means
  - Public health hazards resulting from mold, mildew, and disease due to flood water
  - Flooded or destroyed lifelines/supply routes including US Highway 101
  - Damaged or destroyed utilities, including on campus power generation
  - Loss of community economic base
  - Employment losses
  - Agricultural (crops and livestock) damages or destruction
  - Environmental damage
  - Prolonged periods of necessary dewatering
  - Flooding erosion may alter natural drainage channels
  - Threat, inundation, or damage to on campus childcare facilities and occupants
  - Societal and community impacts
  - Psychological impacts of impacted populations
  - Disruptions to education delivery to community

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped
by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

**Probability of Future Occurrence of the Hazard**

The area surrounding the Sonoma state University campus does not generally promote conditions for flood waters to accumulate. There are specific buildings and areas of the campus that have a greater risk for isolated flooding. The Sonoma State University campus is located within a Zone X Special Flood Hazard Area (Minimal Flood Hazard). The Copeland Creek runs along the northern border of the campus and is classified as Zone AE Special Flood Hazard Area (Area Inundated by 1% Annual Chance of Flooding) within the creek channel. However, there is a historic record of isolated urban or street flood events provides a demonstration of potential flood activity.

The probability of future occurrence for flooding is **Possible**.

**Vulnerability to the Hazard**

The Sonoma State University campus is subject to the effects of flooding primarily resulting from potential urban flooding due to heavy precipitation that overwhelms drainage systems on campus, based on excessive precipitation during isolated heavy storms, river/levee overflow, or a combination of these. The vulnerability to flood among the people and infrastructure is reduced as the campus is located in an area designated as having a minimal flood risk.

There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of the campus or Rohnert Park due to overflow or damage to drainage or flood control systems. The flood control channels and drainage systems that surround the campus have limited storage or volume capacities. Vulnerability to flooding on the Sonoma State University campus will vary depending on when the flood was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks.

It is unlikely, but should an urban flood occur, impacts may pertain to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Sonoma State University is in a location adjacent to surrounding residential communities that have the potential for flooding. When these areas are inundated with flood water, the potential for access barriers, contaminant release into flood waters, and creating physical isolation presenting vulnerabilities to individuals from the campus community regarding challenges to health and safety. The area surrounding the campus is filled with agricultural land uses, flooding of these areas may result in agricultural contaminants to be released into flood waters.
During low probability, severe flood events, all campus buildings and infrastructure would be vulnerable to large-scale flooding reaching the university. Campus utilities and communication capabilities would be impacted by flood waters rendering them disabled. A low probability flood covering a large portion of the city would likely affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. Flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Finally, certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $289,079,090. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

The primary vulnerabilities to flood are exposed people and campus assets (e.g., low-lying buildings, open building sites, and structures with exposed generators, HVAC, critical control systems, or other key components) mostly by localized flooding from isolated or large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. While the Sonoma campus is removed from designated flood zones, the campus remains vulnerable to localized floods due to heavy rains or overflow of campus creeks.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community.
level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.
Hazardous Materials

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”73 Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

Fixed Hazardous Materials Incident: A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

Transportation Hazardous Materials Incident: A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

Pipeline Incident: A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health.74 Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations

- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness

**Natural-Technological Incidents (Natechs)**: During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. The planning committee indicates that chemicals are located in the science lab on campus, and asbestos is located in various buildings. Mapping indicates two hazardous waste sites and a rail line are about one mile from the campus. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city and county of Sonoma, and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

For the Sonoma State planning committee, chemicals are managed in the campus science lab while asbestos in various buildings requires ongoing abatement. Chemical spills may have taken place, though not verified. Also, the rail line potentially imposes risk long-term, though currently it is used for passenger transport only. Based on

---

these factors, along with the close proximity of hazardous waste sites within 1/4 mile, the extent of the hazard for the CSU – Sonoma campus is Low to Moderate. That said, it is prudent to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

For more details on specific hazmat events, please refer to the local, county and/or multi-jurisdictional hazard mitigation plans where CSU campuses are located at: https://www.caloes.ca.gov/cal-oes-divisions/hazard-mitigation/hazard-mitigation-planning/local-hazard-mitigation-program

According to the campus planning committee, chemical spills may have taken place though not verified. Asbestos present in buildings requires abatement/removal, and while it poses risks does not constitute a hazmat incident.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly

lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also to some degree apply to the students, staff and environment on the CSU – Sonoma campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

Potential Impact of the Hazard (Natechs)

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Sonoma) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded

---

81 Source: 2018 California State Hazard Mitigation Plan, section 9.2.
underground tank sites (e.g., gas stations or chemical storage facilities), propane
tanks, manure or human waste handling facilities, fertilizer and pesticide storage,
agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which
destroyed approximately 6,000 residences) entire neighborhoods can be burned to the
ground. Hazardous material release creates public health concerns which can delay
the initial steps of fire recovery, including reopening burned areas to residents and
initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming
into contact with toxic substances due to the presence of synthetic and hazardous
materials. 82

Probability of Future Occurrence

The probability of occurrence for a hazmat event on the CSU – Sonoma campus can
be viewed in two different ways: the history of occurrence serves as a sound predictor
of future probability assuming current risk and vulnerability factors remain somewhat
constant. For the purposes of the current estimate, no current data clearly indicates
otherwise. As such, the probability of occurrence is Low - the campus has experienced
no verified chemical spills in the science lab, and asbestos abatement is being
addressed. In addition, hazardous waste sites are in fairly close proximity which may
increase vulnerability and the probability of a campus-related event. Hazmat
occurrences are largely based on human error, and any changes in risk and
vulnerability factors such as a decreased vigilance in materials oversight and handling
practices or changes in the amount of material or exposure will likely increase the
probability on campus.

Assessment of Vulnerability

Hazardous materials pose a risk to the CSU – Sonoma campus. As identified by the
campus planning committee and on the hazmat map, the following vulnerabilities are
present on campus: chemicals in the science lab, and asbestos in various buildings
pose health risks. Mapping indicates two hazardous waste sites and a rail line and a
gas pipeline grouped about ¼ mile and 1 mile from campus respectively. While the
rail is passenger only, that could change in the future. As such, due to their somewhat
close proximity, gases and chemicals or hazardous waste, if spilled or released, could
impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because
(unlike natural hazards) the probability of occurrence is dependent on human error,
which itself is variable based upon a fluctuating set of interrelated factors, some of
which lack prediction or control, given the complexity of how all natural and built
environments and hazmat risks factors interrelate at the local or campus level, it is

82 Source: 2018 California State Hazard Mitigation Plan, section 9.2.
prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Sonoma leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including Sonoma State) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Sonoma County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Sonoma campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste
Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The Sonoma State planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

Landslide

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow.11 These landslides may impact lives and properties within the deposition zone and can result in

downstream flooding. Post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 25-14. Based on the Figure below, the CSU-Sonoma campus is located close to areas susceptible to landslide.
**Extent of the Hazard**

In Sonoma County, landslides are more likely to occur in the steep slopes outside of the metropolitan area. The hills and canyons surrounding Rohnert Park contribute to widespread landslide hazard and the indirect impacts of landslides may cover a larger geographical exten, possibly including the campus. Based on the campus’ proximity to the landslide hazard zone, and the history of significant impacts in the Sonoma area, the planning committee ranks the extent of the landslide hazard for the campus as *Moderate.*

---

History of the Hazard
Sonoma County has a high number of historic debris flows recorded by NOAA, with sixty on record between 2006 and 2019. Most of these landslides have occurred north and west of Santa Rosa in the foothills, although two of these occurred just outside of Rohnert Park. FEMA has declared 10 major disasters since 1982 that include landslides or mudslides, all triggered by storms or flooding. No landslides have occurred on or immediately adjacent to the campus.

Potential Impacts of the Hazard
CSU Sonoma may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard
Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in Sonoma County and therefore are highly likely to occur in the future. Rohnert Park, however, is relatively flat and has little risk of future landslides. Impacts from landslides outside of city limits are expected to be indirect and minor. Given the location of the campus somewhat close to the landslide zone, the planning committee ranks the probability of the landslide hazard in some way affecting the campus as Possible.

Vulnerability to the Hazard
The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground
deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress.

Any population proximal to a landslide when it occurs is vulnerable to its impacts. The campus does not exhibit structural vulnerabilities, though transportation routes surrounding the campus remain vulnerable.

**Estimate of Potential Losses**

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Sonoma.

**Vulnerability Assessment Conclusions**

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**

The ability to predict future landslides at the CSU Sonoma campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.

---

**Power Outage**

**Description of the Hazard**

Rohnert Park, is a town in Sonoma County, California. It is the home of Sonoma State University.

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave populated areas like Rohnert Park without basic service, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.
A power outage event can interrupt day-to-day operations of the Sonoma State campus, like in-person classes, impede or limit digital, telephonic, or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of Sonoma State student residents in on-campus housing would also be affected by a power outage on campus and in the area. A severe outage to Sonoma County or the City of Rohnert Park would also directly affect the campus and the community.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions are:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

Extent of the Hazard
In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of “stage alerts” to the media based on system conditions. The alerts are as follows:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard

Sonoma State has experienced power outages due to wildfires created by high wind extreme heat events. In 2019, during the Kincaid fire PSPS was used to reduce the impact of the disaster to the area. Due to the challenges PSPS may bring in the future, developing a solar microgrid may prove to be highly necessary for campus resilience.

Potential Impacts of the Hazard

Instructors, campus residents, staff, and administration rely on electricity for basic operations. During a widespread power failure, it may take anywhere from several hours to days to restore operations if a significant event occurs. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.
Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. Sonoma county experiences such outages. As such, the probability ranking for the Sonoma area is **Likely**. Since the campus has also recorded power outage events, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the probability of future occurrences prompting intentional outages and creating unintentional power outages the hazard is high for the county in different areas but not specifically influencing Sonoma State. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

Although the campus has specific power outage protocols, an outage can impact the operations of the university depending on the severity of the outage. During daytime hours, the University may remain open and business and instructional operations will remain on-going at the maximum extent possible. It will be expected that the areas surrounding the campus, including streetlights, will have also experienced a blackout.
During dark hours staff, students and faculty are to remain on campus for fifteen minutes in the event that power returns. In the event that the power returns business and instructional operations will resume. If power is not restored, instruction will stop, and business operations will stop for the remainder of the evening. Classes and university operations and projects utilizing hazardous materials are required to immediately stop to avoid additional hazards.

Estimate of Potential Losses

The data provided by Sonoma State does not report any value for potential losses due to power outage.

Vulnerability Assessment Conclusions

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Sonoma State. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely. The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

Sonoma State did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.

**Volcano (Associated Air Quality)**

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked
storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location”. 85

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. 86 The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard
There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU Sonoma or Sonoma County is located within a volcano hazard zone.

Extent of the Hazard
Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While Sonoma State does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

The dashed lines in Figure 25-15 enclose areas where two inches or more of ashfall are possible. However, it should be noted that hazard maps are dynamic and updated periodically as research adds new information.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As Sonoma State is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be
widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Sonoma.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the planning committee ranks the annual probability of future occurrence as Unlikely.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For Sonoma State, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions
Sonoma State is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of

87 State of California Hazard Mitigation Plan, September 2018
combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. The Sonoma State University campus is located in a suburban setting in the Santa Rosa Plain. This plain is surrounded by hills largely covered in moderate to high fuel density areas. In general, areas considered to be within Local Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur east and west of the campus. These hills surrounding Sonoma County communities can be topographically diverse, contain heavier vegetative fuels, and often have residential development interspersed.

The Sonoma State University campus is located in the eastern portion of the City of Rohnert Park. The area immediately surrounding the campus is predominately developed with residential land uses. Residential neighborhoods exist to the south and west of the campus. The campus has open agricultural fields to the east and north of the campus. The area to the east of campus is designated as a Local High Fire
Hazard Severity Zone. To the north of the campus, are residential neighborhoods and a valley containing Ward Creek containing heavy fuels.

The CSU Easy Bay, Concord campus is located in the hills of Concord near the base of Mt. Diablo. The area immediately surrounding the campus is predominately developed with residential neighborhoods. The campus has open fields containing short grasses and moderate fuels to the south and west of the campus. The area to the south of campus is designated as a Local High Fire Hazard Severity Zone. To the north of campus are agricultural fields and residential neighborhoods across Rohnert Park Expressway, however dense vegetation and trees line Copeland Creek between the campus and the road.

Figure 25-15: Sonoma County Fire Hazard Severity Zones

Extent of the Hazard

While the threat to fire directly affecting the campus is considerable, the direct effect of fire generated smoke is also likely to occur. Fires are likely to occur in close
proximity to the campus generating smoke that could envelop the campus in the right atmospheric conditions. Fires that are large enough to generate volumes of smoke to cover great distances have the potential to affect the air quality of the Sonoma County area including the campus. This will especially be the case in weather conditions creating strong off-shore winds. The potential for this impact has been demonstrated during the summers of 2018, 2019, and 2020 as fires burned across the state and spread smoke over vast distances. Fires burning well outside of the Sonoma County region have the potential to distribute smoke onto the Sonoma State University campus.

Given the occurrence of 5 Federal Declarations in Sonoma County from 2003 to the present (with 4 of those declarations made since 2015), along with the fact that Fire Hazard Severity Zones are found throughout the hillsides surrounding the campus, the planning committee ranks the extent of the wildfire hazard for the campus as High. The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel -- especially draped fuel -- may burn hot. Short-distance spotting may occur but is not</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CLASS 3: High Danger (H)</th>
<th>Fires start easily and spread at a rapid rate</th>
<th>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>CLASS 4: Very High Danger (VH)</th>
<th>Fires start very easily and spread at a very fast rate</th>
<th>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>CLASS 5: Extreme (E)</th>
<th>Fire situation is explosive and can result in extensive property damage</th>
<th>Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</th>
</tr>
</thead>
</table>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke.
The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.

*Includes acreage across two counties (Sonoma and Napa)

Fire has contributed significantly to Sonoma County’s hazard and disaster history. Some particular fires that have shaped the way fire plays into preparedness, planning, response, recovery, and mitigation efforts are described in the following.

The October 2017 Tubbs Fire would become the most destructive wildfire in California history at the time. Strong winds, drought, low humidity, heavy fuels, and inadequate separations between fuels and structures allowed a fire to ignite and rapidly spread. The fire was one of multiple fires that was simultaneously burning in Northern California. This fire clearly demonstrated the challenges faced in a wildland urban interface environment. The loss of thousands of homes in northern Santa Rosa resulted as the fire developed into a fast-moving fire with extreme fire behaviors. The fire required a massive mutual aid effort forced the evacuation of tens of thousands of residents, burned 5,643 structures, killed 22 people, and resulted in $1.4 billion in damages.

Potential Impacts of the Hazard

The location of the Sonoma State University campus surrounded by areas designated as Very High Fire Hazard Severity Zones places a threat of flame, ember, and smoke exposure from wildfire to the campus. There is potential for fire to occur on three sides of the campus and in the surrounding hillsides composed of light to moderate fuels. The threat of these neighboring hillsides to campus structures is substantial.

Potential impacts to the campus community resulting from wildfires include:

---

90 Sonoma County Hazard Mitigation Plan Update, April 2017
- Injuries or loss of life
- Campus property destruction of damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Sonoma County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard
Based on the wildfire threat potential in the area on and surrounding the Sonoma State campus, including the immediate proximity to hillsides with extensive vegetative growth, including the immediate proximity to Fire Hazard Severity Zones listed as “Moderate” to “High”, and the historic occurrences of fires, the probability of wildfire related damage is considered **Likely**.

Based on the wildfire threat potential in the area surrounding the campus and the San Francisco East Bay region, including the volume of areas in elevated Fire Hazard Severity Zones throughout the Sonoma, Marin, and Napa Counties, the past occurrences of wildfire generated smoke from areas beyond Sonoma County, the probability of wildfire generated smoke impacts to air quality is considered **Possible**.

**Vulnerability to the Hazard**

The Sonoma State University campus is subject to direct impact from wildfire due to the campus location within a wildland-urban interface zone. The campus is identified to reside near a designated local High Fire Hazard Severity Zone. The campus is surrounded on by hillsides and open lands containing combustible vegetation combined with residential development. Additionally, vulnerabilities to the effects of wildfire would lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillsides and extending onto the campus or localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have significant impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures. Structures with vegetation and other combustibles near the structure increases the ability of fire to spread to buildings.

Access to the north and south using Petaluma Hill Road and US Highway 101 servicing access to Santa Rosa or San Francisco could become cutoff during fire incidents. Routes to the east are smaller roadways exiting the back of campus that would also likely be impacted by fire making them impassible. The university is limited by these routes for access to and from the campus. Access for supplies, equipment, and emergency services in addition to evacuation away from the campus would likely be forced to use alternative routes into Santa Rosa or south to the Bay Area.
Additional concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Bay Area even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. Sonoma State University students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the Sonoma State University campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $289,079,090. However due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Sonoma County, including wildfire incidents that have threatened or caused damages near the Sonoma State University campus. The location of the Sonoma State University campus surrounded by open hillsides with light to moderate vegetative fuels along the entire eastern edges presents a threat of fire to the campus community and campus assets. The foothills and mountains surrounding Sonoma County host environments that are ideal for the development of wildfire activity. The consequences of fires in these areas would present primary and secondary consequences to the Sonoma State University campus and expose vulnerabilities on the campus and to the campus community.

The topography of the valley surrounded by mountains allows for smoke filled air to linger in the valleys of Sonoma County area with the potential for unhealthy air quality depending on wind conditions. Fires in the watersheds of the surrounding mountains and tributaries may damage vegetation stabilizing hillsides and result in increased sediments to be discharged into the river system and reservoirs reducing their capacity and effectiveness.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.
Severe Weather (Wind, Tornado, Hail, and Lightning)

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific.

---

93 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat
lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.95

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California.96 On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions.97 This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including Sonoma State University.

**Regional Climate Influences on Severe Weather across California**

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.98

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including Sonoma State), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.99

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.\textsuperscript{100} The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.\textsuperscript{101} These storms affect (in varying degrees) all CSU campuses, including Sonoma State.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{102} Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.\textsuperscript{103} Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{104} *Severe thunderstorms* are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\textsuperscript{105,106}

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.\textsuperscript{107}

- **Wind storm**: marked by high wind with little or no precipitation.\textsuperscript{108}

\textsuperscript{102} Retrieved on 07.14.2021 from https://www.weather.gov/phi/ThunderstormDefinition
\textsuperscript{104} Retrieved on 07.14.2021 from https://www.noaa.gov/explainers/severe-storms
\textsuperscript{105} Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
\textsuperscript{106} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\textsuperscript{109}
- **Coastal storm**: Large wind-driven waves and/or storm surge that strike the coastal zone.\textsuperscript{110}
- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\textsuperscript{111}
- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\textsuperscript{112}

### Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

#### Wind Hazards

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a

force, pushing the high towards the low pressure.\textsuperscript{113} Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” \textsuperscript{114}

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including Sonoma State).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\textsuperscript{115}

**Strong Winds**

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\textsuperscript{116}

**Thunderstorm Winds**

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\textsuperscript{117}

Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\textsuperscript{118} However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

\textsuperscript{114} Retrieved on 07.15.2021 from https://forecast.weather.gov/glossary.php?word=wind%20gust
\textsuperscript{115} Retrieved on 07.17.2021 from https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf
\textsuperscript{118} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/
Tornadoes

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth. This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes. On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.

Santa Ana Winds. A type of wind hazard that is peculiar to Southern California is called a Santa Ana Wind. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico). They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape. (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

119 Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/
120 Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/syrwx101/tornadoes/faq/
121 Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions
**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.\(^\text{125}\)

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and

---

\(^{124}\) Retrieved on 07.14.2021 from [https://twitter.com/nwslosangeles/status/933049473034579968](https://twitter.com/nwslosangeles/status/933049473034579968)

\(^{125}\) Retrieved on 07.13.2021 from [https://www.fireweather.org/diablo-winds](https://www.fireweather.org/diablo-winds)
coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.\(^{126}\)\(^{127}\)\(^{128}\)

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.\(^{129}\) It is roughly round in shape and at least 0.2‘ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.\(^{130}\)

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\(^{131}\)

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\(^{132}\) Lightning that is produced

---

from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

Location of the Hazard

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the Sonoma State campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

Extent of the Hazard

Severe weather hazards are non-spatial hazards that potentially affect all Sonoma State campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to Sonoma State reflect those of the surrounding community and County. As a result, all assets and people at Sonoma State are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Rohnert Park area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as MODERATE. See each sub-hazard below for the planning committee’s sub-type extent ranking.

Wind Hazard: Non-Rotational

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.
Extent: Tornado

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.136

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 25-28: Fujita Tornado Scale (Pre-February 2007) 137

<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as **LOW**.

*Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events*

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no established, objective severity scale for thunderstorms.\(^{141}\) \(^{142}\) That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light, medium, or heavy* according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\(^ {143}\)

\(^{141}\) Retrieved on 07.15.2021 from [https://www.noaa.gov/explainers/severe-storms](https://www.noaa.gov/explainers/severe-storms)

\(^{142}\) Retrieved on 07.15.2021 from [https://www.weather.gov/safety/thunderstorm](https://www.weather.gov/safety/thunderstorm)

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass.\(^{144}\)

- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion.\(^{145}\)

- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\(^{146}\) \(^{147}\)

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

History of the Hazard

Severe weather hazards have been an annual occurrence in Sonoma and on the Sonoma State campus. Historical data for these hazards are presented below.

Historical Storm Data Collection: NCEI Storm Events Database

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\textsuperscript{148} For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\textsuperscript{149} To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Sonoma County since 1996.\textsuperscript{150} Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\textsuperscript{151}

- **High Wind**: at least 90 events, or approximately 3.55 events per year\textsuperscript{152}

\textsuperscript{150} National Climatic Data Center. Storm Events Database. Retrieved 07.19.2021 from https://www.ncdc.noaa.gov/stormevents/
\textsuperscript{151} National Climatic Data Center. Storm Events Database. Retrieved 07.19.2021 from https://www.ncdc.noaa.gov/stormevents/
\textsuperscript{152} National Climatic Data Center. Storm Events Database. Retrieved 07.31.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SONOMA%3A97&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA
- **Strong Wind:** at least 219 events, or 8.64 events per year\(^{153}\)
- **Thunderstorm Wind:** at least 7 events, or approximately 0.28 events per year\(^{154}\)
- **All Wind Hazard events** (excluding Tornadoes): at least 310 events, or approximately 12.24 events per year.\(^{155}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Sonoma County, there have been at least 310 wind hazard events since 1996, excluding tornadoes.\(^{156}\) That translates to an approximate average historical frequency of occurrence of **12.24** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 316 events) and simultaneous Database searches of all severe weather hazard events (i.e., 310 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Sonoma County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{157}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 310 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical Wind Hazard Losses for Sonoma County since 1996

According to the NCEI Storm Events Database, the wind hazard events that Sonoma County has experienced since 1996 have been costly. There have been 5 deaths and 5 injuries, and property damage estimates have totaled approximately $3,859,000; there have been no crop damages reported.158

Tornado Wind Hazards

Information from the NCEI Storm Events Database indicates that since 1996, there have been 6 reported events of tornadoes in Sonoma County, which translates to approximately 0.24 tornado events per year.159 The majority of tornadoes that have occurred in Sonoma County have been rated at the F1/EF1 severity level, with the remaining tornadoes rated at the F0/EF0 severity level.160

Historical Tornado Hazard Losses for Sonoma County since 1996

According to the NCEI Storm Events Database, the tornado hazard events that Sonoma County has experienced since 1996 have been costly. While there have been no tornado-related deaths, there has been 1 injury, and property damage estimates have totaled approximately $1,204,000; crop damage estimates have been minimal (i.e., $500).161

Hail

Information from the NCEI Storm Events Database indicates that since 1996, there have been 21 reported events of hail in Sonoma County, which translates to approximately 0.83 hail events per year.162 (Note: The NCEI Storm Event Database search results for hail

indicate that there has been a total of 22 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Sonoma County. The origin of this error is unknown at this time.

**Historical Hail Hazard Losses for Sonoma County since 1996**

According to the NCEI Storm Events Database, since 1996, there have been no deaths, injuries, property damage, or crop damage attributed to hail in Sonoma County.163 (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Sonoma County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been three (3) reported event(s) of lightning in Sonoma County, which translates to approximately 0.12 lightning events per year.164

**Historical Lightning Hazard Losses for Sonoma County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Sonoma County has experienced since 1996 have been costly. While there have been no deaths there has been 1 injury, and property damage estimates have totaled approximately $1,000,000; no crop damage has been reported.165

Information obtained from the NCEI Storm Events Database indicates that there have been 340 occurrences of the severe weather hazard in Sonoma County. This translates to **13.42** severe weather hazard occurrences per year.\footnote{166}

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 347 events) and simultaneous Database searches of all severe weather hazard events (i.e., 340 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;", and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Sonoma County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\footnote{167}

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 340 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Sonoma County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Sonoma County has experienced since 1996 have been costly. There have been 5 deaths and 7 injuries, and property and crop damage estimates have totaled approximately $6,062,000 and $500, respectively.\footnote{168} *It is important to note that for all Sonoma County severe weather hazard events recorded on the Storm Events Database, all deaths, most injuries, and almost two-thirds of all estimated property damages have been attributed to wind hazard events alone; tornadoes and lightning hazard events have comprised 19.9% and 16.5% of the remaining property damage estimates, respectively.*

**Wind Hazards Not Included in the NCEI Storm Events Database**

*Santa Ana Winds*

\footnote{166} National Climatic Data Center. Storm Events Database. Retrieved 07.31.2021 from \url{https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Hail&eventType=%28Z%29+High+Wind&eventType=%28C%29+Lightning&eventType=%28Z%29+Strong+Wind&eventType=%28C%29+Thunderstorm+Wind&eventType=%28C%29+Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SONOMA%3A97&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA}

Santa Ana wind events occur at least twice per month from October through April.\textsuperscript{169} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textit{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6 days accounting for 90\% of all occurrences. The remaining 10\% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{170, 171}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

**Diablo Winds**

Diablo wind events occur approximately *2.5 events per year*. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.¹⁷⁴

---

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\(^{175}\)

Figure 25-19: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\(^{176}\)

\[\text{Sundowner Winds}\]

Strong sundowner wind events occur approximately \textbf{2-3 times per year}. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\(^{177}\)

\[\text{Historical Frequency of All Severe Weather Hazards}\]

**Potential Impacts of the Hazard**

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within Sonoma State University campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the Sonoma State campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.
Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

According to the 2018 City of Rohnert Park Local Hazard Mitigation Plan, wind hazards (including tornadoes) are not considered to be hazards of concern for the city; this means that wind hazards and tornadoes are considered to have low significance and therefore minimal potential impact on the city. However, the Sonoma County Multijurisdictional Hazard Mitigation Plan Update 2021 rates the severe weather hazards of “damaging winds” and tornadoes as having a MEDIUM risk of impacting the Sonoma County planning area (i.e., a moderate potential impact rating). Although the Sonoma State University campus is located within the Rohnert Park planning area, the city is surrounded by the Sonoma County planning area. Therefore, to accommodate both jurisdictional hazard mitigation plans, wind hazards and tornadoes are considered to have a low to moderate potential impact on the Sonoma State campus and surrounding areas.

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

According to the 2018 City of Rohnert Park Local Hazard Mitigation Plan, hail is not considered to be a hazard of concern for the city; this means that the hail hazard is considered to have low significance and therefore minimal potential impact on the city. However, the Sonoma County Multijurisdictional Hazard Mitigation Plan Update 2021 rates the severe weather hazards of “thunderstorms, lightning, and hail” as having a medium risk of impacting the Sonoma County planning area (i.e., a moderate potential impact rating). Although the Sonoma State University campus is located within the Rohnert Park planning area, the city is surrounded by the Sonoma County planning area. Therefore, to accommodate both jurisdictional hazard mitigation plans, hail hazards are

---

considered to have a low to moderate potential impact on the Sonoma State campus and surrounding areas.

**Lightning**

Lightning strikes the United States about 20-25 million times a year.\(^{182}\) Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.\(^{183}\) Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.\(^{184}\) (Commercial claim payouts for lightning losses for the U.S. were not available.)

According to the 2018 City of Rohnert Park Local Hazard Mitigation Plan, the lightning hazard is not considered to be a hazard of concern for the city; this means that lightning hazards are considered to have LOW significance and therefore LOW potential impact on the city.\(^{185}\) However, the Sonoma County Multijurisdictional Hazard Mitigation Plan Update 2021 rates severe weather hazards of “thunderstorms, lightning, and hail” as having a medium risk of impacting the Sonoma County planning area (i.e., a moderate potential impact rating).\(^{186}\) Although the Sonoma State University campus is located within the Rohnert Park planning area, the city is surrounded by the Sonoma County planning area. Therefore, to accommodate both jurisdictional hazard mitigation plans, lightning hazards are considered to have a low to moderate potential impact on the Sonoma State campus and surrounding areas.

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The City of Rohnert Park Local Hazard Mitigation Plan does not consider severe weather hazards significant enough to

---

\(^{184}\) Retrieved on 07.21.2021 from https://www.iii.org/table-archive/20504

However, the Sonoma County Multijurisdictional Hazard Mitigation Plan Update 2021 states there have been over three (3) damaging severe weather events per year (on average) since 2000; as a result, the Plan rates the probability of a severe weather event impacting the planning area as “high.” Also, according to the NCEI Storm Events Database, severe weather wind hazard events have occurred in Sonoma County far more than once per year – at an average of 12.24 times per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the Sonoma State campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the Sonoma State campus reflect those of the surrounding community and County, identified in the Table below.

Based on the data available from the Rohnert Park and Sonoma County hazard mitigation plans, as well as the data from the NCEI Storm Events Database, the severe weather hazard (in the form of the wind hazard) is expected to occur on (or otherwise impact) the Sonoma State campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for Sonoma State is HIGHLY LIKELY. See Table below for probabilities of future occurrence for component severe weather hazards for the Sonoma County and the campus.

Table 25-33: Severe Weather Hazard Probabilities of Future Occurrence for Sonoma County and Sonoma State University.

Vulnerability to the Hazard

People, structures, and assets on the Sonoma State campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The Sonoma State campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire Sonoma State campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within the Sonoma State University campus are at risk from severe weather. There are approximately 45 buildings on the main campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $289,079,090 for 37 of the buildings, and are unknown for the remaining 8 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at the Sonoma State campus varies throughout the day. As of Fall, 2019, Sonoma State had 8,649 students and 1,338 faculty and staff. All are at risk from severe weather events, with 9,987 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

** Note: The Santa Ana and Sundowner wind hazards are not present in Sonoma County, and therefore are not rated for probability of future occurrence. They are included here for information purposes only.

---

| Santa Ana Wind** | 32 | Not Rated |
| Sundowner Wind** | 2 to 3 | Not Rated |
| Severe Weather Hazard | **Highly Likely** |

---

Severe weather presents a variety of hazards to the Sonoma State campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to Sonoma State.

It is evident that the Sonoma State campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
25.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Sonoma campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
Table 25-34: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>

</tr>
</tbody>
</table>

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**
In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Table 25-35: Campus-specific emergency management issues of concern and inclusion in emergency management plans and processes.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Has a good relationship with food banks in the area; limitation is no refrigeration in food pantry.
- Have counseling and psych services involved in the emergency management process; in the EOC; when anticipate events, the director of psych and counseling is part of the process.
- Digital equity will be part of the 2020 EOP update; under audit for accessibility on the webpage.
 Communications are in English, so vast amounts of details are more difficult for non-English-speaking families.
 LGBTQI are not part of the planning documents; cited housing vulnerabilities for former foster youth due to sexual orientation.
 Transportation dependency is a “big one”; don’t have buses but have vans and a relationship with the county.
 There are health vulnerabilities during the PSPS.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

Table 25-36: CSU Sonoma *Highly Likely, Likely and Possible* Hazards

</tbody>
</table>
**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods. Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states. Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young

and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.193

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Cold**

Research shows that excess morbidity and mortality occurs during cold weather periods. We critically reviewed evidence relating temperature variability, health outcomes, and adaptation strategies to cold weather. Health outcomes included cardiovascular-, respiratory-, cerebrovascular-, and all-cause morbidity and mortality. Individual and contextual risk factors were assessed to highlight associations between individual- and neighborhood- level characteristics that contribute to a person’s vulnerability to variability in cold weather events.

Skin exposure to cold weather may render one susceptible to adverse health outcomes.194 Respiratory tract infections are more likely to occur during periods of low temperatures and low humidity. Socioeconomic indicators related to morbidity and mortality do not appear to strongly contribute to a person’s susceptibility to cold weather. However, the role of socioeconomic status is not clear as some evidence implies that income disparities and fuel poverty contribute to cold-related mortality.195

---

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices. This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underlying tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes. It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases. The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6°F. Hypothermia occurs when your body temperature falls below 95°F. As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Heat

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitoes that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.
Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 196

**Flood**

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher

---

percentages of populations such as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. 197

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural health and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, anger, sadness and grief. 198 Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity.  

Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of

---

ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs. 202

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.203

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

26.1 University Profile

University History

Stanislaus State University was established in 1957. The university offers 45 Bachelor's degrees, 17 Master's degrees, one Doctoral degree (Doctor of Education), and 6 teaching credentials. The California State Legislature established what was then called Stanislaus State College as the 15th campus of the CSU system. Classes began on the Stanislaus County Fairgrounds in September of 1960, and the college moved to its current location five years later. The college was first accredited in 1964.

Stanislaus State University is designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

Governance at Stanislaus State University is guided by the concept of “shared governance.” Shared governance recognizes that the university president ultimately has authority and responsibility for decisions affecting the university. The university benefits from a process of joint decision-making and consultation, wherein mutual responsibility is essential. This collaborative work manifests primarily as shared governance informed by robust consultation. Consultation between the faculty and the administration within this context is defined as a mutual exchange of information, ideas, opinions, and recommendations from initial formulation to final determination of policy and procedures affecting the operations of those areas where primary responsibility rests with the faculty.

University Mission

“The faculty, staff, administrators, and students of California State University, Stanislaus are committed to creating an inclusive learning environment which encourages all members of the campus community to expand their intellectual, creative, and social horizons. We challenge one another to realize our potential, to appreciate and contribute to the enrichment of our diverse community, and to develop a passion for lifelong learning.”

To facilitate this mission, university promotes academic excellence in the teaching and scholarly activities of the university faculty, encourage personalized student learning,
foster interactions and partnerships with our surrounding communities, and provide opportunities for the intellectual, cultural, and artistic enrichment of the region.

University Location

California State University, Stanislaus is located in Turlock within Stanislaus County, California. Aside from the main campus in Turlock there are additional campuses in Lodi/Stockton, Ceres, Merced and a satellite campus in Turlock.

University Population

In the Fall of 2020, Stanislaus State University had 11,163 students enrolled. 54% of the student population were of Latino/Mexican-American/Chicano heritage. The second largest student population are White students making up 22.6%. A majority of undergraduate students are first generation and full-time, and many are Pell Grant eligible.

26.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph
Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction's risks where they vary from the risks facing the entire planning area.

26.3 Hazard Identification and Risk Assessment

Overview of California State University, Stanislaus History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 26-1 (following).
Table 26-1: Hazard Identification Determinations

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

Highly Likely- 76%-100% that the hazard would occur annually.
Likely- 50%-75% that the hazard would occur annually.
Possible- 11%-49% that the hazard would occur each annually.
Unlikely- 0%-10% that the hazard would occur each annually.
**Communicable Disease**

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products, and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague).

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff.

---

populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 26-2 below.)

**Descriptions of Identified Communicable Disease Hazards at Stanislaus State University**

Stanislaus State University identified one communicable disease hazard that had the greatest impact on campus – COVID-19. The following is a brief description of the communicable disease hazard at Stanislaus State University.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that...
originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data have shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It’s not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death. 5

---

Location of the Hazard

Communicable diseases have the potential to affect the entire Stanislaus State University (STANISLAUS STATE UNIVERSITY) planning area equally. As a result, this hazard can be found both at main campus of Stanislaus State University located in Turlock, CA (Stanislaus County), and at the Stanislaus State University satellite campus in Stockton, CA (San Joaquin County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) both Stanislaus State University locations are at risk of exposure.6

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. Table 26-4 shows the number of students that were living in CSU-campus-owned housing in Fall, 2019, prior to the CVID-19 pandemic. For Stanislaus State University, approximately 8% of its 10,614 enrolled students (or 849 students) reside in student housing7 8

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

8 California State University. CSU Campus Match. Retrieved 04.30.2021 from: https://www2.calstate.edu/attend/campuses/campus-match/Pages/campus-match.aspx
Figure 26-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall into these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

**Figure 26-1: Biosafety Levels (BSLs)**

---

**The Extent of Stanislaus State University COVID-19 Communicable Disease Hazard:**

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.10

CSU-campus-specific COVID-19 case data for Stanislaus State University can be found in the *History of the Hazard* section below.

**History of the Hazard**

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported **54** cases of COVID-19 at Stanislaus State University. Most communicable disease data are maintained by at the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-

---

19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 26-5 to 26-7 include confirmed COVID-19 cases since May 2020 involving STANISLAUS STATE UNIVERSITY students, faculty or staff who may have exposed others while working, visiting, attending in-person instruction, or living on campus (student housing) during the illness, as well as cases for Stanislaus and San Juaquin counties. (Note: Case numbers are reported on a weekly basis, and reflect numbers through the previous Saturday. The website is updated by the following Wednesday by close of work.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the Stanislaus State University campuses. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of CSU campus populations contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of Stanislaus State University students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic, and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU – Stanislaus) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g.,

---

a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).14

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 26-7: WHO Risk Group Categorization15

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 26.9 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level

for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 26-8: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG I</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

---

These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

### Probability of Future Occurrence of the Hazard

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency. Table 26-10 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:
Table 26-9: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at both Stanislaus State University campuses.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, the CSU System had 480,541 students and 53,763 faculty and staff. Stanislaus State University had 10,614 students and 1,276 faculty and staff.17 18 Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree in the current COVID-19 pandemic on the Stanislaus State University campuses.

Estimate of Potential Losses

The COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In

17 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

18 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including Stanislaus State University) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

Economic Impact of COVID-19 Pandemic on CSU Financial Health

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 26.2 below for the economic impact to Stanislaus State University). Several CSU campuses saw refund losses surpass $10 million. (See Figure 26-2)

Figure 26-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of

26-21
Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would
likely overwhelm available on-campus medical services and could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 26-13 below for the “10% outbreak scenario” projections for Stanislaus State University and for the entire CSU System.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*
While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system (including Stanislaus State University). In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

---

**Dam and Levee Failure**

**Description of the Hazard**

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water.
into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtoppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

Stanislaus County is home to a variety of flood control facilities and levee systems throughout the county. Turlock sits in the heart of the San Joaquin Valley surrounded by agricultural land and between the Sierra Nevada mountains and the Coastal Ranges.

There are dam facilities in Stanislaus County to the east of the city including Modesto Reservoir and Turlock Lake.

The county is additionally downstream of facilities located in other counties. There are dam facilities east of the city in Tuolumne and Mariposa Counties containing significant amounts of water. The Don Pedro Reservoir Dam regulates the Tuolumne River, and the New Exchequer Dam regulates the Merced River. Both eventually feeding into the San Joaquin River. Failures of these facilities are expected to produce inundations that cover sizable areas around Turlock. The Stanislaus State University campus is located within the Don Pedro Dam inundation area but not within the New Exchequer Dam inundation area.

27 California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- High hazard potential dams may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- Significant hazard potential dams are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- Low hazard potential dams are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and

---

28 California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

</table>

The Stanislaus State University campus lies within the inundation zone of the Don Pedro Dam listed above. In the event of a catastrophic failure of the identified dams, the Stanislaus State University campus is expected to be in the inundation area covering the entire campus along with the entire community surrounding the campus. The entirety of Turlock would experience the effects of water inundation damage as the water is expected to fan out across much of this portion of the San Joaquin Valley. Additionally, there are multiple transportation corridors, utilities, and other critical infrastructure that lie within the dam inundation zones that could compromise transportation routes, service options, and areas the campus community reside or work. Based on the above factors, the planning committee ranks the extent of the hazard as Moderate.

Extent – Levee Failure

Levees have been constructed to protect portions of Stanislaus County outside of Turlock. A series of levees have been constructed to protect lands alongside the San Joaquin River in eastern Stanislaus County. Additionally, levees line parts of the Tuolumne River north of Turlock. The Stanislaus State University campus is not located in a levee protected area. Based on the above factors, the planning committee ranks the extent of the hazard as Low.

History of the Hazard

There are no records of dam or levee failures in areas that present a threat to the Stanislaus State University campus. Stanislaus County has no record of dam failures:

Table 26-14: Stanislaus County Dam Failures

30 Stanislaus County Local Hazard Mitigation Plan Update, July 2017
Potential Impacts of the Hazard

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

**Probability of Future Occurrence of the Hazard**

Stanislaus County is determined to be at risk from dam and levee failure in many parts of the county. The location of the Stanislaus State University campus downstream from the Don Pedro and New Malones dams demonstrates that the potential exists for future dam related issues. The City of Turlock including the Stanislaus State University campus resides within the dam inundation zone for the Don Pedro Dam. The entire City of Turlock remains outside of levee protected zones. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on no historical dam or levee failure occurrences, the likelihood of this hazard is low – dams and levees are high priority infrastructure that undergo careful and consistent monitoring and maintenance.

The probability of future occurrence for both dam and levee failures is **Unlikely**.

**Vulnerability to the Hazard**

Given High Priority dam monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. In addition, the campus does not lie within an inundation zone. However, in the unlikely event of a catastrophic failure, the effects of flooding from compromised dams and levees on campus would most likely be limited to indirect or secondary effects in terms of disruption to regional transportation networks and services, and the amount of time to respond to the needs of the campus community prior to inundation will be limited.

Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational
intelligence provides adequate information as to compromised locations. These variables place all those working and living within dam inundation and flood protection zones in vulnerable locations in the event of a low probability, catastrophic event.

The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the Stanislaus State University campus areas are unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in the vulnerability of numerous displaced individuals and households. The lack of flood insurance will cause additional and extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the Stanislaus State University campus will vary depending on the degree of breach or structural failure and when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $162,376,793. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at Stanislaus State University.

**Vulnerability Assessment Conclusions**

While the occurrence of dam and levee failures have not been historically relevant near the Stanislaus State University campus, the potential for hazards related to the region’s levees and dams still exist. Additionally, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in
the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences would be catastrophic to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs (of available data) due to dam and levee failure are $162,376,793.
Drought

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water. The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - Stanislaus) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified throughout Stanislaus County and the City of Turlock where CSU - Stanislaus is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to the campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously in the state, with 80-100% of the state impacted for 12 of the last 20 years.  

**Extent of the Hazard**

Although the extent of drought on campus is identified as minimal, given the historical occurrence of drought impacts throughout the city and county surrounding the planning area, and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. Although drought affects the entire CSU system-wide planning area equally, the extent of the hazard is variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. That said, the extent of the hazard on campus is reported to be Low due to the use of award-winning water retention/conservation ponds and recycled water for mitigating prolonged drought impacts to campus grounds and the campus research garden.

In addition, drought related land subsidence has occurred statewide and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in

serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Though these effects have not been reported on campus, they remain issues of concern for the campus over the long term.

Although the campus planning team identifies the extent of the hazard as Low (qualitatively) which corresponds to D0 – D1 on the Extent scale (below), Sonoma County has experienced more severe drought conditions, including D4 levels during the statewide event from 2012-2017. As such, the campus planning team recognizes that while historic impacts shaping the extent of drought on campus have been minimal, the potential impacts are tied to trends across larger geographic areas, and, therefore, the committee recognizes that the extent of drought on campus has the potential to increase in the future.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

Water shortages are widespread; surface water is depleted; federal irrigation water deliveries are extremely low; junior water rights are curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor;

History of the Hazard

Although no occurrences of drought are reported specifically for the campus, historically, drought has been so prevalent in California that its presence is almost continuous. According to the US Drought Monitor, Time Series data, Stanislaus County (which encompasses the City of Turlock and the campus) has experienced 8 periods of drought covering 12 of the last 20 years, including the severe statewide event from 2012-2017.

Figure 26-5: Periods of Drought in Stanislaus County, CA, 2001 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.34

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 26-6: Periods of Drought in State of California, 2001 – 202135

![California Percent Area](image)

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the county and city surrounding the CSU - Stanislaus campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012 - 2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2

billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.36

**Potential Impacts of the Hazard**

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the city, county and region surrounding the planning area are a sub-set of larger and inter-connected regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the CSU - Stanislaus campus planning area is a potential reduction in water availability for the municipal area tied to the campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - Stanislaus to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of the campus’ agricultural and drought research garden. That said, the campus utilizes recycled water and developed a set of water retention/conservation ponds designed to reduce the potential impacts tied to water scarcity.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such.37 However, the wildfire hazard is analyzed separately in this plan.

In reviewing the occurrences of drought for Stanislaus County and the city of Turlock (which surround CSU - Stanislaus), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - Stanislaus, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campus. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.

At present, drought related damage to campus buildings and infrastructure at CSU - Stanislaus has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - Stanislaus is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Stanislaus. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Probability of Future Occurrence

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence in the state in any given year. Given that CSU – Stanislaus lies within a drought impacted region, with drought having occurred during 12 of the last 20 years, is prudent to extend the Highly

---

Likely probability of occurrence to the campus planning area, even though drought risk is ranked as Low by the campus planning committee.

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Stanislaus campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - Stanislaus planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

Vulnerability of Populations

Drought vulnerabilities on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities may apply to the students, faculty and staff of the CSU - Stanislaus campus over the long term.

**Property Vulnerability**

Drought vulnerabilities for property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities may apply to the properties of the CSU - Stanislaus campus over the long term.

**Natural Environment Vulnerability**

Drought vulnerabilities for the campus’ natural environment are primarily the flora/landscaping on campus grounds, and the agriculture and flora tied to the campus’ research garden. In response, the campus has tried to reduce the vulnerability by installing a series of water conservation ponds and by utilizing recycled water. On a broader scale, drought vulnerability is widespread throughout public and private lands within the state, including tree mortality, potential impacts to all flora and fauna, and potential destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping natural resource vulnerability on campus, in Turlock and Stanislaus County and throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**
Drought vulnerabilities for CSU - Stanislaus’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence over the long term.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought-related losses to the City of Turlock and county of Stanislaus, and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
**Earthquake**

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture**  – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction**  – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.
**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. Stanislaus State University is located in the northern San Joaquin Valley. In general, fault systems extend along the mountain ranges on the eastern and western edges of the valley a distance from Stanislaus State University. There are no known fault systems in the immediate area surrounding the campus.
The Stanislaus State University campus does not reside in areas designated to be liquefaction zones.

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The
The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 26-8: Earthquake Magnitude and Equivalent Energy Release

---

Based on the earthquake shaking potential in the Stanislaus County area, the campus’ proximity to five fault systems and history of occurrence, the extent of the earthquake risk is considered **Moderate**.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Stanislaus County also has history of earthquake activity especially on the western side. Stanislaus County has a limited history of significant earthquakes occurring in the central part of the County including where Stanislaus State University is located.

**Potential Impacts of the Hazard**

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. Earthquakes are unlikely to be centered in Stanislaus County. However, a major earthquake in Stanislaus County would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Turlock could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Turlock could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire.

---

44 Stanislaus County Local Hazard Mitigation Plan, July 2017
Local impacts to Stanislaus State University campus caused by an earthquake could include:

- Potential hazardous material releases on and off campus
- Infrastructure damage to State Route 99
- Damages to rail lines and rail cars 1 mile from campus
- Structural damage to bridges over waterways and flood control channels
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to flood control levees
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences and businesses
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the fault systems surrounding Stanislaus County and Turlock is included in the following table.

Table 26-20: Major Potentially Active Faults in Proximity to Stanislaus State University 45

45 Stanislaus Multi-Jurisdictional Hazard Mitigation Plan, 2017
While seismic activity is not common in Stanislaus County, counties to the west and east are at high risk for earthquakes. The fault systems described above each reside outside of the county but have the potential to effect Stanislaus County. The USGS indicates the likelihood of an earthquake of magnitude 5.0 occurring within 50km of the county in the next 50 years is 80.62%. Based on the earthquake shaking potential in the areas east and west of the Stanislaus County area, the proximity to the San Andreas, Calaveras, Greenville, Ortigalita, and the Sargent Fault Systems, the probability of seismic ground shaking generating damage is considered Possible.

**Vulnerability to the Hazard**

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region tend to remain to the west along the Coastal Ranges and to the east in the Sierra Nevada Mountains. Many of these cross major transportation routes potentially reducing the availability of access and the supply chain. However, Turlock is likely less vulnerable to the direct effects of earthquake as known fault systems are removed from the area. The geographic location of Turlock sits at the base of river systems that have deposited sediment from the surrounding mountains. In many cases, these sediment-based soils are loose and expose the potential for liquefaction. The soils of the area surrounding the campus are described by the Local Hazard Mitigation Plan as generally being not conducive to significant liquefaction due to a high clay content.

The known fault systems generating the threat to Turlock generally exist to the east and west of the city but do not cross into the city including the Stanislaus State University campus. The distance to these surrounding systems help mitigate significant vulnerabilities in the event a seismic event were to occur on those systems. In the event of an earthquake occurring in the region on an unknown system, the potential for earthquake damaged structures being left uninhabitable including campus residence halls

47 Stanislaus Multi-Jurisdictional Hazard Mitigation Plan, 2017, p.45
will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the Stanislaus State University campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the city. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with sheltering and care of those unable or unwilling to return to their homes. Damages to the homes of the members of the campus community may place greater demands on campus resources and capabilities in the short-term period following a seismic event.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**
Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions. Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $162,376,793.

*Buildings with no value defined are also included in the respective Zones they are found in.
Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the Turlock area and the Stanislaus State University campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the Stanislaus State University campus and community.

In the event that a major earthquake was to strike along the fault systems surrounding Turlock, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Stanislaus County region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.
Erosion

Description of the Hazard
The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.” Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard
Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. As such, for the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the Stanislaus State University campus with erosion-prone characteristics. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area.

Extent of the Hazard
There is no published scale of severity or extent for this geologic hazard. If conditions are favorable, erosion is likely to occur. Given no historical occurrence of erosion on campus, and no known areas of erosion, the planning committee ranks the extent of this hazard as Low.

History of the Hazard
There have been no recorded incidents of erosion on the Stanislaus State University campus.

Potential Impacts of the Hazard
Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

In agricultural areas, the erosion of soil degrades the quality of the soil, which can lead to reduced crop yields. At the Sustainable Garden, soil erosion can create significant concerns for agriculture and research. Eroded test plots can negatively impact experiments and tests, resulting in a loss of knowledge and data.

**Probability of Future Occurrence of the Hazard**

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, the probability of at least a limited degree of future occurrence is high over the long term.

**Vulnerability to the Hazard**

Topography, soil structure, land use, and precipitation are all factors of erosion. Stanislaus State University infrastructure, buildings, and agriculture located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. CSU leadership may consider performing an analysis to identify such at-risk buildings, infrastructure, slopes and soil types in the future.

In the wider Stanislaus community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

**Vulnerability Assessment Conclusions**

While the ability to predict future erosion on the Stanislaus State University campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

---

**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.50

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.51 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperature “feels” hotter. The combination of temperature and humidity is known as the heat index.52

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.53 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.54

**Location of the Hazard**

Extreme heat events are a non-spatial hazard, and may occur at the Stanislaus State campus.

**Extent of the Hazard**

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the high 80s to mid-90s in the City of Turlock, where the campus is located. According to data from the National Climatic Data Center (NCDC), the highest daily

52 Ibid.

temperature recorded in the City of Turlock was 111° F on two sequential days, July 23, 2006 and July 24, 2006. These high temperatures were part of an extended period of excessive heat that affected much of the state of California. Heat index values reached as high as 119° F. Given the historical occurrence of numerous extreme heat events, the planning committee ranks the extent of the hazard as Moderate.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria.55 In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 26-9 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

As the heat index rises, so does the potential danger to people and animals. Table 26-22 (following) shows the health hazards associated with extreme heat.

Table 26-21: Health Risks Associated with Heat Index

</tbody>
</table>

History of the Hazard

Data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database shows two excessive heat events that have impacted Stanislaus County since 2007:

**May 8, 2007; July 5, 2007:** 2007 was one of the driest years on record for most California counties, which fueled at least 9,000 separate wildfires.

In addition to these declared heat events, the NCEI has recorded nearly 400 separate dates between 1986 and 2019 when the air temperature in the City of Turlock was at or above 100° F.

Potential Impacts of the Hazard

Stanislaus State University may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact

research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

Given over 400 days with temperatures at or above 100 degrees from 1989 – 2019 (30 years), more than 10 such events will occur per year on average. As such, extreme heat is Highly Likely to occur annually.

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat and are more likely to suffer illness or death as a result.57 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Stanislaus State University is aware of the potential for extreme heat events. In addition to any warnings issued by the county, the campus will notify students and staff via the Stanislaus State University emergency notification system, StanAlert. The university advises students to find an air-conditioned space, stay hydrated, avoid high-energy activities, and check yourself and others for signs of heat-related illness. In the case of a power outage during an extreme heat event, the decision to close campus is made by the President or other Executive Designee.

While this is a hazard that the campus may experience regularly, the campus has ample familiarity with appropriate steps to take in order to handle the risks and vulnerabilities.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

__________________________

While the ability to predict future heat events at the Stanislaus State campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), North-Central California has warmed about 1.5 – 2 degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.58

**Identified Data Limitations**

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

### Flood

**Description of the Hazard**

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in

significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Floods can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected. **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.
Atmospheric Rivers

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.

Figure 26-10: Introduction to Atmospheric Rivers
Location of the Hazard

Turlock lies in the northern portions of the San Joaquin Valley at the base of the Sierra Nevada Mountains. The San Joaquin River, Merced River, Tuolumne River, and creeks between the rivers have been identified as the primary flood sources for Stanislaus County. The eastern portions of Stanislaus County are primarily mountainous terrain of the Sierra Nevada Mountains. The Merced River watershed encompasses 1,726 square miles of drainage above New Exchequer Dam. The watershed receives the majority of its water from snowfall generating 479,000 acre-feet of surface water run-off into the Merced River. The Tuolumne River watershed drains an area of 1,958 square miles into the Tuolumne River generating 1,850,000 acre-feet of water through northern Stanislaus County.

The Stanislaus State University campus is located 7 miles south of the Tuolumne River. The Merced River lies 10 miles to the south of the campus. The entire Stanislaus State University campus sits within a Zone X: Area of Minimal Flood Risk. There are no flood hazard zones located in Turlock or in proximity to the campus.
Extent of the Hazard

The Stanislaus State University campus is located entirely in a designated Zone X: Minimal Flood Hazard. The entire City of Turlock also is located within the Zone X: Minimal Flood Hazard. The access routes into and out of the campus servicing Stanislaus County locations are found in areas designated as Zone X: Minimal Flood Hazard.

The Stanislaus State University campus also lies outside of a levee flood protected area. Levees protect areas at the base of the foothills and lining flood control channels. This specific hazard does not substantially alter the ability of the campus to maintain operations as the distance to levee protected channels exceeds the protection zones. However, members of the campus community residing in these areas could be heavily affected with damages to their homes, and access to campus could be limited, as well as student financial capacity to support ongoing education being diminished. Based on the campus’ location within an area of minimal flooding and no history of flooding in or near the campus, the planning committee ranks the extent of the flood hazard on campus as Low.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBMs), Flood Insurance Rate Maps (FIRMs), and Flood Boundary and Floodway Maps (FBFMs). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 26-22: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>

<tr>
<td>Zone X (unshaded)</td>
<td>Undetermined</td>
<td>Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.</td>
</tr>
</tbody>
</table>

**History of the Hazard**

Flooding in Stanislaus County has typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. However, the documented flooding incidents in Stanislaus County have...
occurred along the San Joaquin, Tuolumne, and Merced Rivers and not specifically in Turlock or near the campus. Table 26-24: Historic Flooding Events in Turlock60

Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations

---------------------
60 Stanislaus County Local Hazard Mitigation Plan, July 2017
- Disruptions to education delivery to community
- Contamination and potential exposure from standing water with chemical, bacterial and other toxic substances

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

**Probability of Future Occurrence of the Hazard**

Stanislaus County is determined to be at high risk from flooding. The location of the Stanislaus State University campus and the entire City of Turlock resides outside of any Special Flood Hazard Area. The potential exists for urban flooding due to heavy precipitation and the remote chance for effects from dam, levee, or river flooding.

Based on the campus location outside the SFHA, and on no occurrences of flooding near the Stanislaus State University campus, the probability of future occurrence for flooding is **Unlikely** on an annual basis, but **Possible** over the long term.

**Vulnerability to the Hazard**

The Stanislaus State University campus is subject to the effects of flooding resulting primarily from excessive precipitation and isolated strong storms. Strong storms producing localized heavy accumulations of water on campus present the most likely scenario for flooding events to face the campus. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of Turlock due to overflow or damage to distant flood control systems. However, when these systems are inundated with flood water, the potential for displacement of people exists presenting possible impacts to individuals from the campus community.

Vulnerability to flooding on the Stanislaus State University campus will vary depending on when the flood were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks.

It is unlikely, but should an urban flood occur, impacts may pertain to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing
precipitation, the speed of the storms moving across the area, the level of snowpack in
the higher elevations, and amount of resulting snowmelt will produce varying effects on
damages produced and costs incurred. Losses will be generated by the physical
damages, the loss of revenue, loss of academic research, loss of building contents, and
community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the
maximum total replacement costs due to flood are $162,376,793. However, it is unlikely
for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

The potential for highly unlikely, severe flooding on the campus and surrounding area
generates the potential for a number of cascading effects such as disruptions to the local
economy, utility failures, disruptions to providing for the needs of the campus and the
community, and development of public health hazards. These effects would be
exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive
run-off from the watershed contributing to the river system. The potential for widespread
flooding and damage of structures due to the force of water, while unlikely, has
exponentially powerful impacts on particular segments of the campus community
including those with access or functional needs, international students, the homeless, and
students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete
inventory of both building construction features and mitigation efforts to lessen the impact
due to flood inundation. HAZUS generated analysis is focused on the broader community
level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Hazardous Materials**

**Description of the Hazard**

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”61 Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

---

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. The planning committee indicates that chemicals are located in the science lab. Mapping indicates two hazardous waste sites are about ½ mile from the campus, and a chemical site and gas pipeline that runs adjacent to the east side of campus. Also, Pacific Rail carrying toxic chemicals such as ethanol is about 1 mile away. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city and county of Stanislaus, and reflect different types, configurations and scales dispersed across these geographic areas.

Figure 26-12: National Pipeline Map Near Stanislaus

---

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

For the CSU – Stanislaus planning committee, chemicals are well managed in the campus science lab and only small quantities are stored. Chemical spills have not taken place. But the rail line adds to the extent of the risk – it carries toxic chemicals that if released during a derailment, could produce toxic gas impacting the campus directly downwind of the rail line. Based on these factors, along with the somewhat close proximity of hazardous waste sites within 1/2 mile, the extent of the hazard for the CSU – Stanislaus campus is **Low to Moderate**. That said, it is prudent to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. 66 That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and

---

recover from immediate disaster threats, and that responsible parties may have an
incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the California Governor’s Office of Emergency Services’ Hazardous
Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April
2021, a total of 2,096 spill events had occurred so far this year. Such events have occurred
in all the cities and/or counties where CSU campuses are located.67

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-
technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past
earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

For more details on specific hazmat events, please refer to the local, county and/or multi-
jurisdictional hazard mitigation plans where CSU campuses are located at:
https://www.caloes.ca.gov/cal-oes-divisions/hazard-mitigation/hazard-mitigation-
planning/local-hazard-mitigation-program

According to the campus planning committee, no hazmat events have occurred on

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under
certain conditions related to direction of air flow (air-based chemical release) and
population density or the contamination of a community’s main water supply. Either type
of release could necessitate large scale evacuation. By contrast, in the rural
unincorporated areas where population densities are low, even in the event of a large
release, the number of homes that may need to be evacuated would be significantly
lower than in an urban environment. The occurrence of a hazmat incident can also result
in the shut-down of transportation corridors which can last for hours at a time while the
impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if
absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources
become unsafe and unusable, depending on the amount of contaminant. Some
chemicals cause painful and damaging burns if they come in direct contact with skin.
Prolonged and concentrated exposure to such chemicals can produce severe long-term
impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also to some degree
apply to the students, staff and environment on the CSU – Stanislaus campus.

https://w3.calema.ca.gov/operational/malhaz.nsf/$defaultView?OpenView&Start=121&ExpandView
With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health.68 Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Stanislaus) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials. 69

**Probability of Future Occurrence**

69 Source: 2018 California State Hazard Mitigation Plan, section 9.2.
The probability of occurrence for a hazmat event on the CSU – Stanislaus campus can be
viewed in two different ways: the history of occurrence serves as a sound predictor of
future probability assuming current risk and vulnerability factors remain somewhat
constant. For the purposes of the current estimate, no current data clearly indicates
otherwise. As such, the probability of occurrence is **Low** - the campus has not
experienced a hazmat event and chemicals in the science lab are well managed. That
said, hazardous waste sites are in fairly close proximity and the rail line carrying
chemicals may increase vulnerability and the probability of a campus-related event.
Hazmat occurrences are largely based on human error, and any changes in risk and
vulnerability factors such as a decreased vigilance in materials oversight and handling
practices or changes in the amount of material or exposure will likely increase the
probability on campus.

Assessment of Vulnerability

Hazardous materials pose a risk to the CSU – Stanislaus campus. As identified by the
campus planning committee and on the hazmat map, the following vulnerabilities are
present on campus: chemicals are well managed in the campus science lab and only
small quantities are stored. The campus actively addresses this vulnerability and held a
full exercise in the lab in 2018. But the Pacific rail line adds to the extent of the risk –
though 1 mile away, it carries toxic chemicals that if released during a derailment, could
produce a toxic gas cloud impacting the campus directly downwind of the rail line. As
such, gases and chemicals or hazardous waste, if spilled or released, could impact human
health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because
(Unlike natural hazards) the probability of occurrence is dependent on human error, which
itself is variable based upon a fluctuating set of interrelated factors, some of which lack
prediction or control, given the complexity of how all natural and built environments and
hazmat risks factors interrelate at the local or campus level, it is prudent to assume for
planning purposes that the campus’ vulnerability is a sub-set of the larger community’s
vulnerability. As such, the CSU – Stanislaus leadership maintains vigilance to mitigate the
campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate
quantitative measure of vulnerability because of the variable nature of a hazardous
materials spill. For example, the release of a toxic airborne chemical in a populated area
has severe impact potential, whereas the impact potential of a small chemical spill in a
remote or rural area is most likely limited to remediation of soil. And, in both cases, the
probability of occurrence is dependent on human error, which itself is variable based
upon a fluctuating set of interrelated factors, some of which lack prediction or control. In
all cases, different types and amounts of hazardous materials interact with fluctuating
combinations of human error to produce different event outcomes with variable impact
costs.
Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Stanislaus) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Stanislaus County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Stanislaus campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – Stanislaus planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

Landslide

Description of the Hazard
A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within the deposition zone and can result in downstream flooding. Post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have

occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 26-12. Based on the Figure below, the Stanislaus State University campus is not connected to areas susceptible to landslide.

Figure 26-13: Deep-Seated Landslide Susceptibility Surrounding Stanislaus State University

Extent of the Hazard

Landslide hazards are limited to the foothills of Stanislaus County. However, the indirect impacts of landslides such as disruption of transportation routes in the region may cover a larger geographical extent. Based on the campus’ distance from the landslide hazard zone, the planning committee ranks the extent of the landslide hazard for the campus as Low.

History of the Hazard
FEMA has declared 4 disasters in Stanislaus County since 1983 that involve mud flows, mudslides, or landslides. No landslides have occurred on or immediately adjacent to the campus.

Potential Impacts of the Hazard
Stanislaus State University may be impacted by the disruption of services as a result of landslides in the region. Students, faculty, and staff who live in nearby communities may also be impacted. Landslides can result in physical damage to buildings and property and have the potential to significantly affect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard
Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred rarely in Stanislaus and therefore are not likely to occur in the future. Based on these factors, and the fact that the campus is not located anywhere near a landslide zone, the probability of future occurrence is Unlikely.

Vulnerability to the Hazard
The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and
transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. The campus does not exhibit any such vulnerabilities.

Estimate of Potential Losses
There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to Stanislaus State University.

Vulnerability Assessment Conclusions
Community exposure to landslides varies depending on their physical locations—whether in flat plains or on steep hillsides—and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations
The ability to predict future landslides at the Stanislaus State University campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.
**Power Outage**

**Description of the Hazard**

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave populated areas like Stanislaus County without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the Stanislaus State University campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, hundreds of Stanislaus State University student residents in on-campus housing would also be affected by a power outage on campus and in the area.

Additionally, a severe outage in Stanislaus County would also directly affect the campus and the community. Even though the power provider may be different, the disruption to the surrounding community impacts transportation for commuter staff, faculty, and students.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of **intentional** disruptions are:

- **Planned:** Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- **Unscheduled:** Some intentional disruptions must be done "on the spot" in response to an emergency.
- **Demand-Side Management:** Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- **Load Shedding:** When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- **Accident by the utility, utility contractor, or others.**
- **Malfunction or equipment failure.**
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

**Location of the Hazard**

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

**Extent of the Hazard**

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of “stage alerts” to the media based on system conditions. The alerts are as follows:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given also that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as **Moderate**.

**History of the Hazard**

Stanislaus State University reported experiencing power outages in recent years due to transformer explosions. Their electric utility provider, the Turlock Irrigation District has
experienced outages, which have affected the residents of Stanislaus over the years. Major power outages impacting the City of Turlock in recent years have affected a large number of residents, including the university community. Stanislaus State University did not report any power outages in the recent years at Stanislaus State University but did advise that the university is expanding their mitigation efforts through actions while enacting the business continuity plan and agility recovery strategies. Some of the recent power outage events on campus:

- January 2016: Elevator repairs necessary due to power outage.
- February 2017: Campus wide power outage.
- July 2017: Basement fire led to a power outage.
- March 2018: Appliance overload created a power outage in dining facilities.
- April 2018: Power outage at Warrior Grill. No determination was made for the cause of power loss.

Potential Impacts of the Hazard

Instructors, campus residents, staff and administration rely on electricity to maintain ongoing operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, enabling students with disabilities to enter, navigate and leave University buildings and long-term outages can potentially put students, faculty and staff safety at risk. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions and losing power can potentially lead to tragic results.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat
waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

Probability of Future Occurrence of the Hazard

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. Stanislaus County experiences such outages. As such, the probability ranking for Stanislaus County is Likely. Although the Stanislaus State University campus has recorded fewer events than the surrounding area, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

Vulnerability to the Hazard

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed, campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate and cope with an interruption to electrical power.

Estimate of Potential Losses

Although the economic impact of power outage damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to Stanislaus State University.

Vulnerability Assessment Conclusions

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Stanislaus State University. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and
utilize the campus and its structures safely. The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations
Stanislaus State University did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.

Volcano (Associated Air Quality)

Description of the Hazard
The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard
There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active.

volcanoes. No portion of Stanislaus State University or Stanislaus County is located within a volcano hazard zone.

**Extent of the Hazard**

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While Stanislaus State University does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard off the campus as **Low**.

**History of the Hazard**

Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away. No historical eruption events have affected the campus.

**Potential Impacts of the Hazard**

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As Stanislaus State University is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at Stanislaus State University.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.
Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as **Unlikely**.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For Stanislaus State University, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

Stanislaus State University is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.
Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property. Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another. The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire

75 State of California Hazard Mitigation Plan, September 2018
behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- Fuels – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

Location of the Hazard

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. Turlock is located in the center of the northern San Joaquin Valley between the southern Sierra Nevada Mountains and Coastal Ranges. In general, areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur 16 miles to the east and 18 miles to the west of Turlock. These areas surrounding the valley are topographically diverse, contain heavier vegetative fuels, and often have residential development interspersed. The land in the San Joaquin Valley where the Stanislaus State University campus is located, is largely agricultural, urban, or otherwise developed.

The Stanislaus State University campus is located in the northern portion of the City of Turlock. The area immediately surrounding the campus is predominately developed with residential and commercial land uses. Extensive agricultural fields exist surrounding the city. The campus is established in 2 miles from downtown Turlock. High Fire Hazard Severity Zones are found along the length of the foothills to the Sierra Nevada Mountains and Coastal Ranges. Agricultural areas with extensive crop and orchard production are located on all sides of the city separating areas with wildfire threat by significant distance. There are no areas in proximity to the campus that present direct threats to wildfire.

However, the Stanislaus State University campus is located in the Central Valley surrounded by the mountains and extensive areas of fire hazards. These mountain ranges host three national forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the valley in the right weather conditions. The geography of the Central Valley creates a topography that captures air pollutants including smoke within the surrounding mountains and the development of inversion layers. The Stanislaus State University
campus is located in a region in which is vulnerable to wildfire smoke that can saturate the air around the campus.

Figure 26-14: Fire Hazard Severity Zones near Stanislaus State University

Extent of the Hazard

The area immediately surrounding the Stanislaus State University campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones, and the campus does not have a history of wildfire activity occurring within proximity to the campus. Although the campus is not surrounded by High Fire Severity Zones, it is surrounded by areas that are considered to be of high fire threat and that would produce

76 California Department of Forestry and Fire Protection, Fire and Resource Assessment Program, Fire Hazard Severity Zone Viewer, https://egis.fire.ca.gov/FHSZ/
vast quantities of smoke and particulates into the air. As a result, the planning committee ranks the extent of the wildfire hazard for the Stanislaus State University campus as **Moderate**.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise. Figure 26-15: Air Quality Index for Ozone and Particulate Pollution
The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Stanislaus County also has a long history of wildfire activity primarily in the foothills and mountains of the Sierra Nevada and Coastal Range Mountains. Wildfires occurring in Stanislaus County have resulted in hundreds of thousands of acres burned and millions of dollars in damages. The area immediately surrounding the Stanislaus State University campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Turlock campus has experienced multiple days of poor air quality due to fires burning in the Sierra Nevada and Coastal Range Mountains. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Stanislaus County. Stanislaus State University personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

79 Stanislaus County Local Hazard Mitigation Plan Update, July 2017
Potential Impacts of the Hazard

The location of the Stanislaus State University campus surrounded by areas of urban development removed from areas with a fire hazard places a minimal direct threat from wildfire to the campus. The potential impacts to wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community
Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts on pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Stanislaus County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the wildfire threat potential in the areas surrounding the Stanislaus State University campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered Unlikely.

Based on the wildfire threat potential in the area surrounding the Turlock region, including the volume of areas in elevated Fire Hazard Severity Zones surrounding the San Joaquin Valley, the probability of wildfire generated smoke impacts to air quality is considered Possible.

Vulnerability to the Hazard

The Stanislaus State University campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban/suburban area of Turlock. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of Turlock. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.
Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

Some areas of particular vulnerability on the campus includes:

- Students and staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC will cause limitations in filtering of air during smoke filled days
- Air pollution effects to students housed on the campus
- Power outages or brownouts during days with high levels of smoke will limit shelter in place options during heat events in summer.

The greater concerns regarding vulnerabilities to wildfire on Stanislaus State University are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the San Joaquin Valley even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. Stanislaus State University students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.
Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $162,376,793. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher. However, the location of the campus in an suburban setting removed from hazard prone areas makes wildfire related damages unlikely.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in the mountains surrounding Stanislaus County; however, wildfire incidents do not pose a direct risk to the Stanislaus State University campus. The suburban location of the Stanislaus State University campus surrounded by densely developed residential and commercial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The students, faculty, and staff of Stanislaus State University who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the campus. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to
the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.

Additionally, the topography and weather patterns of Central California often creates conditions that allows for smoke filled air to linger in the Central Valley with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains and forests some distance away that generate tremendous quantities of smoke present tremendous health related vulnerabilities to members of the campus community. The campus community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, and Lightning)**

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding.80 According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”81

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany

severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including Stanislaus State University.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation

82 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat
84 Retrieved on 07.17.2021 from https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions
85 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.\(^{87}\)

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including Stanislaus State University), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.\(^{88}\)

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.\(^{89}\) The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.\(^{90}\) These storms affect (in varying degrees) all CSU campuses, including Stanislaus State University.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\(^{91}\) Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike

---

87 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php

88 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php

Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. **Severe thunderstorms** are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.93 94

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.95

- **Wind storm**: marked by high wind with little or no precipitation.96

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.97

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.98

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick

---

93 Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

94 Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm

to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.99

- **Snowstorm:** A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.100

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.101 Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” 102

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including Stanislaus State University).

**High Winds, Strong Winds, and Thunderstorm Winds**

---

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\(^\text{103}\)

**Strong Winds**

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\(^\text{104}\)

**Thunderstorm Winds**

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\(^\text{105}\)

Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\(^\text{106}\) However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

**Tornadoes**

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\(^\text{107}\) This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed

\(^{106}\) NOAA Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/

\(^{107}\) EarthWorks Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/
that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\textsuperscript{108}

On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{109}

\textbf{Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.}

\textbf{Santa Ana Winds.} A type of wind hazard that is peculiar to Southern California is called a \textit{Santa Ana Wind}. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{110} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{111} (Note: The Wildfire hazard is profiled elsewhere in this document.)

The following figure illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

\end{flushleft}
**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.113

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north.

from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.114 115 116

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.117 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.118

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.119

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.120 Lightning that is produced

---

from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

Location of the Hazard

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including either at the Stanislaus State University main campus or at satellite campus facilities owned by the school. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

Extent of the Hazard

Severe weather hazards are non-spatial hazards that potentially affect all Stanislaus State University campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to Stanislaus State University campuses reflect those of the surrounding community and County. As a result, all assets and people at Stanislaus State University campuses are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Turlock (Stanislaus County) and Stockton (San Joaquin County) areas, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as MODERATE. See each sub-hazard below for the planning committee’s sub-type extent ranking.

Wind Hazard: Non-Rotational

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.  

121 Retrieved on 07.15.2021 from https://www.rmets.org/resource/beaufort-scale

</table>
Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as MODERATE.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.124

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the **date** that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 26-27: Fujita Tornado Scale (Pre-February 2007) 125

<td>&gt;25</td>
<td>&gt;3</td>
</tr>
</tbody>
</table>
Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no established, objective severity scale for thunderstorms.\(^ {129} \)\(^ {130} \) That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light*, *medium*, or *heavy* according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and

\(^ {129} \) Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

\(^ {130} \) Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
- the effect upon surface temperature.\textsuperscript{131}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{132}
- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{133} or
- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\textsuperscript{134, 135}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

**History of the Hazard**

Severe weather hazards have been an annual occurrence in Stanislaus County and on the Stanislaus State University main campus. Severe weather hazards have also been an annual occurrence in San Joaquin County and on the Stanislaus State University – Stockton satellite campus. Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique

\begin{itemize}
\end{itemize}
periods of record available depending on the event type.\(^{136}\) For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\(^{137}\) To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**Stanislaus County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Stanislaus County since 1996.\(^{138}\) Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\(^{139}\)

- **High Wind:** at least 19 events, or approximately 0.75 events per year\(^ {140}\)
- **Strong Wind:** at least 6 events, or 0.24 events per year\(^ {141}\)

\(^{140}\) National Climatic Data Center. Storm Events Database. Retrieved 07.31.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=STANISLAUS%3A99&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA

\(^{141}\) National Climatic Data Center. Storm Events Database. Retrieved 07.31.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+Strong+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=STANISLAUS%3A99&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA
- **Thunderstorm Wind:** at least 7 events, or approximately 0.28 events per year\(^{142}\)

- **All Wind Hazard events** (excluding Tornadoes): at least 26 events, or approximately 1.03 events per year.\(^{143}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Stanislaus County, there have been at least 26 wind hazard events since 1996, excluding tornadoes.\(^{144}\) That translates to an approximate average historical frequency of occurrence of 1.03 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 32 events) and simultaneous Database searches of all severe weather hazard events (i.e., 26 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado;” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Stanislaus County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{145}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 26 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

### Historical Wind Hazard Losses for Stanislaus County since 1996

According to the NCEI Storm Events Database, the wind hazard events that Stanislaus County has experienced since 1996 have been costly. There have been 2 deaths and 5

injuries, and property damage estimates have totaled approximately $5,213,000; no crop damage has been reported.146

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 7 reported events of tornadoes in Stanislaus County, which translates to approximately 0.28 tornado events per year.147 Almost half of the tornadoes have had severity ratings of F1/EF1, while the remaining tornadoes have been rated F0/EF0.148

**Historical Tornado Hazard Losses for Stanislaus County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Stanislaus County has experienced since 1996 have been costly. While there have been no deaths or injuries, property and crop damage estimates have totaled approximately $1,046,000 and $200,000, respectively.149

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 4 reported events of hail in Stanislaus County, which translates to approximately 0.16 hail events per year.150 (Note: The NCEI Storm Event Database search results for hail

indicate that there has been a total of five (5) reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Stanislaus County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Stanislaus County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Stanislaus County has experienced since 1996 have been moderate. There have been no deaths, injuries, or crop damage, and property damage estimates have totaled approximately $5,110.151 (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Stanislaus County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been three (3) reported events of lightning in Stanislaus County, which translates to approximately 0.12 lightning events per year.152

**Historical Lightning Hazard Losses for Stanislaus County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Stanislaus County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop losses, property damage estimates have totaled approximately $220,000.153

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database (Stanislaus County)**

Information obtained from the NCEI Storm Events Database indicates that there have been 40 occurrences of the severe weather hazard in Stanislaus County. This translates to 1.58 severe weather hazard occurrences per year.\textsuperscript{154}

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 47 events) and simultaneous Database searches of all severe weather hazard events (i.e., 40 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Stanislaus County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{155}

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 40 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Stanislaus County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Stanislaus County has experienced since 1996 have been costly. There have been 2 deaths and 5 injuries, and property and crop damage estimates have totaled approximately $6,484,000 and $200,000, respectively.\textsuperscript{156} It is important to note that for all Stanislaus County severe weather hazard events recorded on the Storm Events Database, all deaths and injuries, as well as over 80% of all estimated property damages, have been attributed to wind hazard events alone. All reported crop damages have been attributed solely to lightning hazard events.

**San Joaquin County**

Overall, in San Joaquin County, there have been at least 51 wind hazard events since 1996, excluding tornadoes.¹⁶³ That translates to an approximate average historical frequency of occurrence of 2.01 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 57 events) and simultaneous Database searches of all severe weather hazard events (i.e., 51 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind“ or “Hail” that are reported for San Joaquin County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.¹⁶⁴ When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 51 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for San Joaquin County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that San Joaquin County has experienced since 1996 have been costly. There have been three (3) deaths and five (5) injuries, and property and crop damage estimates have totaled approximately $7,123,000 and $2,000, respectively.¹⁶⁵

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been eight (8) reported events of tornadoes in San Joaquin County, which translates to

approximately 0.32 tornado events per year.\textsuperscript{166} All tornadoes reported in San Joaquin County since 1996 have had severity ratings of F0/EF0.\textsuperscript{167}

**Historical Tornado Hazard Losses for San Joaquin County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that San Joaquin County has experienced since 1996 have been costly. While there have been no deaths or injuries, property and crop damage estimates have totaled approximately $41,000 and $80,000, respectively.\textsuperscript{168}

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been two (2) reported events of hail in San Joaquin County, which translates to approximately 0.08 hail events per year.\textsuperscript{169} (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of three (3) reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from San Joaquin County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for San Joaquin County since 1996**

According to the NCEI Storm Events Database, there have been no deaths, injuries, property damages, or crop damages since 1996 attributed to hail hazard events.\textsuperscript{170} (Note:

\end{itemize}
The San Diego County hail event that was included erroneously in the search results for hail hazard events in San Joaquin County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.

Lightning

Information from the NCEI Storm Events Database indicates that since 1996, there have been two (2) reported events of lightning in San Joaquin County, which translates to approximately 0.08 lightning events per year.\(^{171}\)

Historical Lightning Hazard Losses for San Joaquin County since 1996

According to the NCEI Storm Events Database, the lightning hazard events that San Joaquin County has experienced since 1996 have been costly. While there have been no lightning-related deaths, property damage, or crop damage reported, there have been four (4) injuries.\(^{172}\)

All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database (San Joaquin County)

Information obtained from the NCEI Storm Events Database indicates that there have been 63 occurrences of the severe weather hazard in San Joaquin County since 1996. This translates to 2.49 severe weather hazard occurrences per year.\(^{173}\)

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 70 events) and simultaneous Database searches of all severe weather hazard events (i.e., 63 events) may be due to the following factors: (1)
multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for San Joaquin County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County. When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 63 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical, Aggregated Severe Hazard Losses for San Joaquin County since 1996

According to the NCEI Storm Events Database, the severe weather events that San Joaquin County has experienced since 1996 have been costly. There have been three (3) deaths and nine (9) injuries, and property and crop damage estimates have totaled approximately $7,165,000 and $82,000, respectively. It is important to note that for all San Joaquin County severe weather hazard events recorded on the Storm Events Database, all deaths, five (5) out of nine (9) all injuries, and almost all (99.4%) of all property damage estimates have been attributed to wind hazard events alone. Lighting events have been associated with the remaining four (4) injuries, and almost all (i.e., 97.6%) of the reported crop damage estimates have been attributed to one (1) tornado event in 2005.

Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April. From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting

175 National Climatic Data Center. Storm Events Database. Retrieved on 08.05.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Hail&eventType=%28Z%29+High+Wind&eventType=%28C%29+Lightning&eventType=%28Z%29+Strong+Wind&eventType=%28C%29+Thunderstorm+Wind&eventType=%28C%29+Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SAN%2BJOAQUIN%3A77&hailfilter=0.00&tornfilter=0.0&windfilter=0.000&sort=DT&submitButton=Search&statefips=6%2CCALIFORNIA

up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.\footnote{177} \footnote{178}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

**Diablo Winds**

Diablo wind events occur approximately 2.5 events per year. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.  

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{182}

Figure 26-18: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\textsuperscript{183}

\textbf{Sundowner Winds}

Strong sundowner wind events occur approximately 2-3 times per year. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\textsuperscript{184}

\textbf{Historical Frequency of All Severe Weather Hazards}

Table below shows the average historical frequency of severe weather hazard events for Stanislaus County since 1996.)

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within Stanislaus State University campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the Stanislaus State University campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

**Stanislaus State University Main Campus, Turlock (Stanislaus County)**

The 2017 Stanislaus County Local Hazard Mitigation Plan does not profile wind hazards (including tornadoes), as they are not considered to be significant severe weather hazards for Stanislaus County. As a result, wind hazards are considered to be of low significance, and therefore to have a minimal potential impact on the County and (by extension) the Stanislaus State University main campus.  

**Stanislaus State University – Stockton Campus, Stockton (San Joaquin County)**

The 2018 San Joaquin County Local Hazard Mitigation Plan does not profile wind hazards (including tornadoes), as they are not considered to be significant severe weather hazards for San Joaquin County. As a result, wind hazards are considered to be of low significance, and therefore to have a minimal potential impact on the County and (by extension) the Stanislaus State University – Stockton campus.186

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

**Stanislaus State University Main Campus, Turlock (Stanislaus County)**

The 2017 Stanislaus County Local Hazard Mitigation Plan does not profile hail, as it is not considered to be a significant severe weather hazard for Stanislaus County. As a result, the hail hazard is considered to be of low significance, and therefore to have a minimal potential impact on the County and (by extension) the Stanislaus State University main campus.187

**Stanislaus State University – Stockton Campus, Stockton (San Joaquin County)**

The 2018 San Joaquin County Local Hazard Mitigation Plan does not profile hail, as it is not considered to be a significant severe weather hazard for San Joaquin County. As a result, the hail hazard is considered to be of low significance, and therefore to have a minimal potential impact on the County and (by extension) the Stanislaus State University – Stockton Campus.188

**Lightning**

Lightning strikes the United States about 20-25 million times a year.189 Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.190 Property losses due to lightning have been very

costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.\(^{191}\) (Commercial claim payouts for lightning losses for the U.S. were not available.)

**Stanislaus State University Main Campus, Turlock (Stanislaus County)**

The 2017 Stanislaus County Local Hazard Mitigation Plan does not profile lightning, as it is not considered to be a significant severe weather hazard for Stanislaus County. As a result, the lightning hazard is considered to be of low significance, and therefore to have a minimal potential impact on the County and (by extension) on the Stanislaus State University main campus.\(^{192}\)

**Stanislaus State University – Stockton Campus, Stockton (San Joaquin County)**

The 2018 San Joaquin County Local Hazard Mitigation Plan does not profile hail, as it is not considered to be a significant severe weather hazard for San Joaquin County. As a result, the hail hazard is considered to be of low significance, and therefore to have a minimal potential impact on the County and (by extension) the Stanislaus State University – Stockton campus.\(^{193}\)

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year. Future occurrences of such events are projected to increase in both their frequency and intensity.

**Stanislaus State University Main Campus, Turlock (Stanislaus County)**

The 2017 Stanislaus County Local Hazard Mitigation Plan does not address any severe weather hazards, as severe weather is not considered to be a hazard with significant potential to occur in the County.\(^{194}\) However, according to the NCEI Storm Events Database, some of these same severe weather hazards have occurred in Stanislaus County at least once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the Stanislaus State University main campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather

---

probabilities for the Stanislaus State University main campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2017 Stanislaus County Local Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the Stanislaus State University campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for the Stanislaus State University main campus is HIGHLY LIKELY.

**Stanislaus State University – Stockton Campus, Stockton (San Joaquin County)**

The 2018 San Joaquin County Local Hazard Mitigation Plan does not address any severe weather hazards, as severe weather is not considered to be a hazard with significant potential to occur in the County. However, during the hazard assessment stage of Plan development in 2017, the hazard mitigation planning team provided qualitative rankings of all known hazards in the County; both “High Winds” and “Tornadoes/Thunderstorms” hazards received overall rankings of “Occasional/Likely.” However, according to the NCEI Storm Events Database, wind hazards have occurred in San Joaquin County more than once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the Stanislaus State University – Stockton campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the Stanislaus State University – Stockton campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2018 San Joaquin County Local Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the Stanislaus State University – Stockton campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for Stanislaus State University – Stockton is HIGHLY LIKELY.

**Stanislaus State University – All Campus Areas**

The probability of future occurrence of the severe weather hazard for all Stanislaus State University campus areas is HIGHLY LIKELY.

---

The following tables show the probabilities of future occurrence for component severe weather hazards for Stanislaus State University campuses in Stanislaus County and San Joaquin County.

Table 33: Severe Weather Hazard Probabilities of Future Occurrence for Stanislaus County and Stanislaus State University.

Vulnerability to the Hazard

People, structures, and assets on both Stanislaus State University campuses are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. Stanislaus State University also has vehicles that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects both Stanislaus State University campuses. Each of the hazards associated with severe weather can result in losses throughout the planning area.
All structures at both Stanislaus State University campuses are at risk from severe weather. There are approximately 133 buildings that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $162,376,793 for 86 buildings, and are unknown for the remaining 47 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at Stanislaus State University varies throughout the day. As of Fall, 2019, Stanislaus State University had a total of 10,614 students and 1,276 faculty and staff. All are at risk from severe weather events, with 11,890 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to both Stanislaus State University campuses. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to Stanislaus State University.

It is evident that Stanislaus State University has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural

hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
26.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the Stanislaus State University campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”

Note: CSU Bakersfield was early interview, so interview process and question structure were not yet fully defined enough to include this section.
Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as *Very High, High, Medium, Low*
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as *Yes, No, In Progress, NA*

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.
Table 26-35: Graph of campus-specific emergency management issues of concern and inclusion in emergency management plans and processes.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- EOP has only one paragraph on AFN.
- Seeing a spike now in health and wellness issues. They have rep on the infectious response team and in EOC and talk all the time with county EOC.
- Counselors are available through Telehealth services.
- EAP is encouraged because the isolation is affecting people; can provide services. Student health center is small, and employees are in the high-risk category, but reached out to another health care provider and doing telehealth – so services are available.
- Trained with county for a Point of Distribution (POD).
- Support possible for first responders for isolation.
- Been asked by American Red Cross to be a shelter, if needed.
This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\(^{198}\) Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\(^{199}\) Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the

major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.200

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

---

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.  

**Flood**

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to

---

floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. 202

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural heath and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, anger, sadness and grief. 203 Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. 204 Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old. 205

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality

Indexes track the level of the following:²⁰⁶ particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs. ²⁰⁷

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.²⁰⁸

**Hazard Mitigation and Emergency Management Planning**

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

---

27.1 Chancellor’s Office Profile

University History

The individual California State Colleges were brought together as a system by the Donahoe Higher Education Act of 1960. In 1972, the system became The California State University and Colleges and in 1982, the system became The California State University. Today, the campuses of the CSU include comprehensive and polytechnic universities and, since July 1995, the California State University Maritime Academy, a specialized campus.

The oldest campus, San José State University, was founded in 1857 and became the first institution of public higher education in California. The newest campus, California State University, Channel Islands, opened in fall 2002, with freshmen arriving in fall 2003.

University Governance

In 1960, the Donahoe Higher Education Act brought the individual California State Colleges together as a system. Responsibility for the system is vested in a Board of Trustees, made up of ex officio members, alumni and faculty representatives, and members appointed by the Governor. The Chancellor acts as chief executive officer of the system while the Presidents act as chief executive officers of the respective campuses; both are appointed by the Trustees. Together, the Trustees, Chancellor, and Presidents develop systemwide policy.

University Mission

“The mission of the California State University is:

- To advance and extend knowledge, learning, and culture, especially throughout California.
- To provide opportunities for individuals to develop intellectually, personally, and professionally.
- To prepare significant numbers of educated, responsible people to contribute to California's schools, economy, culture, and future.
- To encourage and provide access to an excellent education to all who are prepared for and wish to participate in collegiate study.
- To offer undergraduate and graduate instruction leading to bachelor's and higher degrees in the liberal arts and sciences, the applied fields, and the professions, including the doctoral degree when authorized.
- To prepare students for international, multi-cultural society.
- To provide public services that enrich the university and its communities.”
To actualize the CSU system’s mission the CSU has committed to the following; quality instruction, value and support a lucrative and inspiring environment for education, help create responsible citizens within a democracy, inspires and educates graduate students to attain the acmes of their educational levels, create opportunity, serve communities throughout California, embrace all cultures and heritage, encourage free scholarly inquiry and curiosity, offer an array of degree programs to all academic and applied areas, and, finally, Offers or proposes to offer instruction at the doctoral level jointly with the University of California and with private institutions of postsecondary education, or independently in the fields of education, nursing, physical therapy, or audiology, where the need is clearly demonstrated.

University Location

The CSU Chancellor’s Office is located in Los Angeles County’s second largest city, Long Beach, California. The office is located along the bay of San Pedro and Long Beach. Long Beach is the southernmost point of Los Angeles County.

University Population

As of 2021, the CSU Chancellor’s Office as system has 481,200 students that attend the university. The CSU produces 62% of the bachelor’s degrees awarded in agriculture, 54% in business, 44% in health and medicine, 64% in hospitality and tourism, 45% in engineering, and 44% of those in media, culture and design. Over the last 10 years, the CSU has significantly enhanced programs towards the underserved. 56% of bachelor’s degrees granted to Latinos in the state are from the CSU, while 60% of bachelor’s awarded to Filipinos were from the CSU system.

27.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.
Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction's risks where they vary from the risks facing the entire planning area.

27.3 Hazard Identification and Risk Assessment

Overview of California State University, Chancellor’s Office History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the highest chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-
To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered XX hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 27-1 (following).

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely** - 76%-100% that the hazard would occur annually.
• **Likely**- 50%-75% that the hazard would occur annually.
• **Possible**- 11%-49% that the hazard would occur each annually.
• **Unlikely**- 0%-10% that the hazard would occur each annually.
**Communicable Disease**

**Description of the Hazard**

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See 27-2 below.)

**Descriptions of Identified Communicable Disease Hazards at CSU Office of the Chancellor**

The CSU Office of the Chancellor has identified one (1) communicable disease hazard that has had the greatest impact on its office – COVID-19. The following is a brief description of the communicable disease hazard at the CSU Office of the Chancellor.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.  

Location of the Hazard

Communicable diseases have the potential to affect the entire CSU Office of the Chancellor space equally. As a result, the communicable disease hazard can be found at the CSU Office of the Chancellor located in the City of Long Beach, CA (Los Angeles County). Because of the ubiquitous nature of many communicable diseases, staff at (and visitors to) the CSU Office of the Chancellor are at risk of exposure to the communicable disease hazard.

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescri...
(e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 27-2 describes the different BSLs, and provides examples of communicable diseases that would typically fall into these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

Figure 27-1: Biosafety Levels (BSLs)\(^6\)

---

The Extent of CSU Office of the Chancellor Communicable Disease Hazards Except COVID-19:

Besides COVID-19, there was no information provided on other communicable disease hazards at the CSU Office of the Chancellor.

The Extent of CSU Office of the Chancellor COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.\(^7\)

*No COVID-19 case data could be found for the CSU Office of the Chancellor.*

History of the Hazard

---

Most communicable disease data are maintained by at the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located. CSU COVID data can be accessed from a publicly available dashboard.

Tables 27-4 and 27-5 show the city- and County-level COVID-19 case data for the City of Long Beach and Los Angeles County, respectively. (The City of Long Beach, where the CSU Chancellor’s Office is located, has its own Health Department that governs public health regulations in that city.) Both the city and County case data are updated on at least a weekly basis.

(Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the CSU Chancellor’s Office. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and

infrastructure integrity may be affected if large numbers of Chancellor’s Office employees contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are essential personnel. Long-term outbreaks affecting large numbers of Chancellor’s Office employees could result in disruptions to the office workflow and, by extension, to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including at the CSU Chancellor’s Office) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

---

Table 27-6: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 27-7 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

---

Table 27-7: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG I</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

Anthrax
West Nile Virus
SARS Virus (Including COVID-19)
Tuberculosis
Typhus
Yellow Fever
Hantaviruses
Avian Flu

These bacteria and viruses cause severe to fatal disease in humans, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

H5N1 (Bird Flu)
Dengue Hemorrhagic Fever
Marburg Virus
Ebola Virus
Smallpox
Lassa Fever
Crimean-Congo Hemorrhagic Fever
Other Hemorrhagic Diseases

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

Probability of Future Occurrence of the Hazard

There have been cases of a variety of communicable disease throughout the CSU system, including COVID-19 (SARS-CoV-2), Meningitis, Measles, Influenza (Including H1N1/Swine Flu), Tuberculosis, Norovirus, Mumps, E. Coli, and Sexually Transmitted Diseases (STDs). However, there are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.
Table 27-8 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 27-8: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence. Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

### Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on staff and visitors at the CSU Chancellor’s Office.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, the CSU System had 480,541 students and 53,763 faculty and staff.) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists.

Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. Due to a lack of information on the COVID-19 statistics for the CSU Chancellor’s Office, it is unclear if this scenario has played out at that location in the current COVID-19 pandemic.

### Estimate of Potential Losses

**COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities**

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

---

13 The California State University. *Enrollment.* Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

14 The California State University. *Employee Head Count by Campus.* Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
At some point in the future, CSU campuses and the Chancellor’s Office will return to full capacity. Without adequate surveillance regarding building access and employee interaction, the Chancellor’s Office is at risk of developing an extreme incidence of COVID-19, and may become a “super-spreader” for adjacent communities.  

The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery at the Chancellor’s Office. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 27-2 below for the economic impact to the campus). Several CSU campuses saw refund losses surpass $10 million. (See Figure 27-2.)

Figure 27-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs.

---

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 27-10.) (Note: There is no information on federal assistance to the Chancellor’s Office.)

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems. Table 27-11 shows the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

</table>
While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational and business disruption, and economic harm to the CSU system, including to the CSU Chancellor’s Office. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Dam and Levee Failure**

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can
occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from over toppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

Los Angeles County is home to a variety of flood control facilities and levee systems mostly along the base of the various mountains and hills throughout the county. Levees have been constructed along numerous flood control channels providing community protection. The CSU Chancellor’s Office is in general proximity to dams upstream along the Los Angeles River and Rio Hondo systems in addition to flood control channels lined with levees.

Figure 27-3: Dams and Levees near CSU Chancellor’s Office
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

The CSU Chancellor’s Office lies outside of the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the CSU Chancellor’s Office is expected to remain out of the inundation area. The inundation area is expected to spread water in areas upstream from the campus and remain within the flood control channels in proximity to the campus. However, there are multiple transportation corridors that lie within the dam inundation zones that could compromise transportation routes and areas the campus community reside or work. Based on these conditions, the planning committee ranks the extent of the hazard on campus as **Low**.

**Extent – Levee Failure**

Levees are used along numerous flood control channels and other waterways including the Los Angeles River, San Gabriel River, and Los Cerritos Channel. The CSU Chancellor’s Office lies outside of the levee flood protected area. In the event any of these channels were flowing at elevated levels and a failure of a levee were to occur, while the campus would not experience direct impacts, the community surrounding the campus would likely experience flood related damages. This specific hazard could alter the ability of the campus to maintain operations as damages would be extensive. Depending on the location of a breach, the campus community would be heavily affected with the loss of life and homes, access to campus would be limited, and student financial capacity to support ongoing education being diminished. Based on these conditions, the planning committee ranks the extent of the levee failure hazard as **Low**.

**History of the Hazard**

There are no records of dam or levee failures in areas that present a threat to the CSU Chancellor’s Office. The City of Long Beach has not identified a history of dam or levee failures elsewhere in the city. Los Angeles County has experienced the following dam failures:

Potential Impacts of the Hazard

**Dam Failure Impacts**

While the campus is not within a dam inundation zone, transportation routes, critical infrastructure, and campus community members may reside within inundation zones. Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues
The area downstream from the San Gabriel, Morris, Santa Fe, and Whittier Narrows Dams includes the populated areas of Los Angeles County. Members of the campus community who reside or are employed in these areas would be most impacted. The campus may experience the same effects from a dam inundation event that would be experienced by the broader region. This would primarily be in the form of transportation routes and other community critical infrastructure being impacted by the inundation. This specific hazard would substantially alter the ability of the campus to maintain operations as damages would be extensive, the campus community in these areas would be heavily affected with the loss of life and homes, and student financial capacity to support ongoing education being diminished.

Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
Reductions in campus revenues

Probability of Future Occurrence of the Hazard

The location of the CSU Chancellor’s Office downstream from the Santa Fe Springs Dam and other flood control facilities along the San Gabriel River and Coyote Creek demonstrates that the potential exists for future dam or levee related secondary impacts. However, the distance from the river channel provides an additional mitigating factor, meaning that the City of Long Beach including the CSU Chancellor’s Office resides outside of known dam inundation zones. Los Angeles River 39 levee system resides immediately to the east of the campus; however, the campus is outside of the levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on historical experience and occurrences and based on consistent dam and levee monitoring and maintenance protocols, the probability of future occurrence for both dam and levee failures is Unlikely.

Vulnerability to the Hazard

The CSU Chancellor’s Office is not subject to the direct effects of flooding resulting from compromised dams and levees. The effects would rather be mostly indirect affecting members of the campus community and regional transportation networks and services. In the case of dam failure, the amount of time to respond to the needs of the campus community prior to inundation will be limited.

The most significant challenge regarding dam failures is they generally result in catastrophic outcomes. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the office community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of flood insurance will cause extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the CSU Chancellor’s Office will vary depending on when the failure was to occur. The risk to the office population will be lessened during periods outside of traditional work hours. Conversely, during the days and hours that personnel are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.
Certain office populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting office infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on site, the total replacement costs due to dam or levee failure are unknown. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU Chancellor’s Office.

**Vulnerability Assessment Conclusions**

While the occurrence of dam and levee failures have not been historically relevant near the CSU Chancellor’s Office, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. The consequences of a dam failure would generate catastrophic results to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the office community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.
**Drought**

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use, versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified throughout Los Angeles County and in the city of Long Beach, where the Chancellor’s Office is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to the campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously in the state, with 80-100% of the state impacted for 12 of the last 20 years. 23

**Extent of the Hazard**

Given the historical occurrence of drought impacts throughout Los Angeles County which surrounds the planning area and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies.

In addition, although drought affects the entire CSU system-wide planning area, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. As such, the planning committee reports the extent of drought to be low for the Chancellor’s Office. Likewise, the City of Long Beach Hazard Mitigation Plan reports a low extent ranking for drought.

In addition, land subsidence has occurred statewide and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural

damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Though these effects are not reported for the Chancellor’s Office, they remain potential issues of concern over the long term.

The CSU Planning Committee ranks the extent of drought as Low for the Chancellor’s Office (corresponding to D0-D1 in the table below), but recognizes that climate change and other factors affecting water supply and usage may increase the extent of the hazard in the future.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor;

History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous. According to the US Drought Monitor, Time Series data, Los Angeles County (which surrounds the planning area) has experienced 6 or more periods of drought covering 13 years from 2000-2021.

Figure 27-5: Periods of Drought in Los Angeles County, California, 2000 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-

________________________

34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 26

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions has been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 27-6: Periods of Drought in State of California, 2001 – 202127

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on Los Angeles County which surrounds the CSU Chancellor’s Office campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to homeowners with dry wells.

According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”’. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at

Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.  

**Potential Impacts of the Hazard**

Drought impacts statewide are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that although no drought impacts have occurred in the planning area, potential impacts exist based on impact risk being a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the state and for the CSU Chancellor’s Office planning area is a potential reduction in water availability for the municipal area tied to the campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU Chancellor’s Office to some extent includes these vulnerable resources based on the campus landscape (trees and flora).

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. However, the wildfire hazard is analyzed separately in this plan. (See wildfire hazard).

In reviewing the impacts of drought for Los Angeles County, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU Chancellor’s Office, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campus. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a

---

risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus; however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.  

At present, drought related damage to campus buildings and infrastructure at the CSU Chancellor’s Office has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU Chancellor’s Office is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including the CSU Chancellor’s Office. A reduction of electric power generation and water quality deterioration are also potential impact factors.

</table>

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence in the state in any given year. Given that CSU Chancellor’s Office lies within a consistently drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area even though drought impacts have not reached the campus up to this point.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream, and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU Chancellor’s Office campus.
Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU Chancellor’s Office planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2 million acre-feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

Vulnerability of Populations

Drought vulnerabilities on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the faculty and staff of the CSU - Chancellor’s Office campus over the long term.

Property Vulnerability

Drought vulnerabilities on property statewide include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting

---

from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities may apply to the properties of the CSU Chancellor's Office campus over the long term.

**Natural Environment Vulnerability**

Drought vulnerabilities on the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds. These same vulnerabilities may apply to the landscaping and flora of the CSU Chancellor's Office campus over the long term.

The core issue shaping the impact of drought throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.34

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for the CSU Chancellor’s Office’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence over the long term.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of Long Beach and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Conclusions**

34 USGS. Forest and Rangeland Ecosystem Science Center. Retrieved 4.29.2021 from: 
https://www.usgs.gov/centers/fresc
The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses (including the Chancellor’s Office) by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.

---

**Earthquake**

**Description of the Hazard**

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to
intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU Chancellor’s Office is located in the southern portion of the Los Angeles Basin. In general, fault systems surround and traverse through Los Angeles and Orange Counties including the area of CSU Chancellor’s Office. Throughout the basin the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 50-55 miles northeast of the CSU Chancellor’s Office. In addition to the San Andreas Fault, Los Angeles County is home to or near additional fault systems with the potential to generate strong ground shaking. The Newport-Inglewood Fault traverses south to north paralleling the Orange County coastline extending within ¾ mile of CSU Chancellor’s Office from the southwest corner of the office. The Palos Verdes Fault crosses the Palos Verdes Peninsula approximately 11 miles east of the campus. The 40-mile-long Compton Fault parallels the Palos Verdes Fault in a southeast to northwest
direction 9 miles east of the CSU Chancellor’s Office. The Whittier-Elsinore Fault extends from the eastern base of the Santa Ana Mountains and western base of the Puente Hills 15 miles to the northeast of the office. There are numerous additional faults in the area on all sides of the office.
The CSU Chancellor’s Office reside entirely within areas designated to be liquefaction zones. Additionally, substantial areas of the community surrounding the office to the north, east, and west also reside within the liquefaction zone. This includes major transportation corridors including Interstate 710, Interstate 405, State Route 1, Ocean Blvd., and Golden Shore Street. The liquefaction zone includes all office facilities.

Figure 27-8: Liquefaction Zones in Proximity to CSU Chancellor’s Office

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale (below) is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy
released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:
Table 27-17: Modified Mercalli Intensity Scale

<table>
<thead>
<tr>
<th>Intensity</th>
<th>Shaking</th>
<th>Description / Damage</th>

<td>Felt quite noticeably by persons indoors, especially on upper floors of buildings. Many people do not recognize it as an earthquake. Standing motor cars may rock slightly. Vibrations similar to the passing of a truck. Duration estimated.</td>
</tr>
<tr>
<td>IV</td>
<td>Light</td>
<td>Felt indoors by many, outdoors by few during the day. At night, some awakened. Dishes, windows, doors disturbed; walls make cracking sound. Sensation like heavy truck striking building. Standing motor cars rocked noticeably.</td>
</tr>
<tr>
<td>V</td>
<td>Moderate</td>
<td>Felt by nearly everyone; many awakened. Some dishes, windows broken. Unstable objects overturned. Pendulum clocks may stop.</td>
</tr>
<tr>
<td>VI</td>
<td>Strong</td>
<td>Felt by all, many frightened. Some heavy furniture moved; a few instances of fallen plaster. Damage slight.</td>
</tr>
<tr>
<td>VII</td>
<td>Very strong</td>
<td>Damage negligible in buildings of good design and construction; slight to moderate in well-built ordinary structures; considerable damage in poorly built or badly designed structures; some chimneys broken.</td>
</tr>
<tr>
<td>VIII</td>
<td>Severe</td>
<td>Damage slight in specially designed structures; considerable damage in ordinary substantial buildings with partial collapse. Damage great in poorly built structures. Fall of chimneys, factory stacks, columns, monuments, walls. Heavy furniture overturned.</td>
</tr>
</tbody>
</table>

Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb. Damage great in substantial buildings, with partial collapse. Buildings shifted off foundations.

Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations. Rails bent.

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

![Figure 27-9: Earthquake Magnitude and Equivalent Energy Release](https://www.usgs.gov/media/images/graph-showing-earthquake-magnitudes-and-equivalent-energy-release)

Based on the history of earthquake occurrences in Los Angeles County, including a near catastrophic event in Long Beach, and the presence of 9 fault systems throughout the

---

county, and ongoing predicted severe events statewide, the planning committee ranks the extent of the hazard as **Moderate**.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Los Angeles County also has a long history of earthquake activity. The entire area of Los Angeles County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The most recent significant earthquake to occur in immediate proximity to Long Beach was in July of 1933. The earthquake occurred on the Newport-Inglewood Fault off of the coast of Newport Beach. The earthquake was felt throughout Southern California and resulted in damages in multiple counties. Long Beach experienced multiple fires, 127 water main breaks, and liquefaction was experienced along the waterfront. Regionally, including Long Beach, 120 people were killed, 5,000 injured, 20,000 homes were damaged, and 75% of schools were destroyed.

---

38 City of Long Beach Hazard Mitigation Plan, February 28, 2017

39 2019 County of Los Angeles All-Hazards Mitigation Plan, 2019
Other earthquakes of significance include, the more recent January 17, 1994 Northridge Earthquake estimated a Magnitude 6.7 earthquake struck at 4:52 am. The earthquake occurred in the San Fernando Valley about 20 miles northwest of Los Angeles. There was widespread damage from buildings, collapsed freeways, and other infrastructure damage. Damages from the earthquake were more than $20B.

The October 1, 1987 Whittier Narrows Earthquake shook a large part of southern California. The earthquake caused $358 million in damages, especially in the Alhambra, Pasadena, and Whittier areas. The earthquake resulted in extensive infrastructure damages, multiple injuries, and 8 fatalities. The earthquake was provided a federal disaster declaration (DR-799).

The February 9, 1971, Magnitude 6.5 San Fernando Earthquake struck the San Fernando Valley in Los Angeles just after 6am. The intense shaking caused the collapse of freeway overpasses, hospitals, and other infrastructure. It damaged thousands of homes and businesses, a reservoir, and critical infrastructure. 65 people were killed and 2,000 more were injured. The shaking was felt for 300 miles including in Las Vegas, Nevada. The earthquake was provided a federal disaster declaration (DR-299).

The Fort Tejon Earthquake, a Magnitude 7.9 earthquake, struck in 1857 along the San Andreas fault just north of Los Angeles County. The earthquake was able to shift the Kern River upstream and run four feet over its banks. Structural damage was limited as the area was sparsely populated at the time. The Fort Tejon Earthquake remains one of the greatest earthquakes ever recorded in the United States producing a surface rupture extending over 220 miles.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the building presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Los Angeles area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Long Beach could cause injuries or fatalities to members of the campus community or support networks the office relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Long Beach could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly
affect the broader Los Angeles County and Orange County region limiting immediate assistance that the campus may normally expect.

Local impacts to the CSU Chancellor’s Office caused by an earthquake could include:

- Damage to nearby refineries and petrol-chemical plants
- Damage and secondary fires to industrial buildings to the west of the office
- Potential hazardous material releases on and off facility
- Potential liquefaction-based effects to most areas of the campus and large areas of the surrounding cities
- Infrastructure to freeway system
- Structural damage to bridges over waterways and flood control channels
- Structural damage to flood control systems
- Potential isolation of office from community
- Potential isolation among office employees and visitors at the time of the event
- Structural damage to San Gabriel River and Los Cerritos Channel levees
- Structural damage to office buildings
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to office operations

The impacts of a major earthquake would be felt beyond the campus and have long reaching effects. The risk of casualties and damages would likely extend to the homes and workplaces of members of the office community including staff and faculty. The effects on the regional economy may be negatively altered as commercial and industrial facilities may not be functional due to damaged goods and/or facilities. The cessation of businesses would result in job losses and greater needs among members of the community. The trauma associated with experiencing a large earthquake often requires mental health assistance to victims and may result in fears to return indoors while aftershocks continue.

**Probability of Future Occurrence of the Hazard**

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in
California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Los Angeles County fault systems surrounding Long Beach is included in the following table.

Based on the earthquake shaking potential in the Los Angeles Basin, the proximity to the above listed fault systems, the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of Long Beach places the office in a busy commercial and industrial areas that is heavily populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the facility. The entirety of the facility is designated as a liquefaction zone and may be impacted by the effects of tidal influences.

The known fault systems generating the threat to Long Beach generally surround the city and some cross into the city, including near to the CSU Chancellor’s Office. The proximity and potential for large earthquake development from these surrounding systems expose

---

40 2019 County of Los Angeles All-Hazards Mitigation Plan, 2019

significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Chancellor’s Office buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the CSU Chancellor’s Office will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the area. This would particularly be seen with greater damages to unreinforced masonry buildings.

Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the office community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a need to assist with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. As the CSU Chancellor’s Office is areas exposed to levee facilities, the decision to evacuate will need to verify whether flood control facilities are filled with water and the actual threat to the dam or levees.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks and find difficulty in accessing equipment or supplies to aid in a specific need.
Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community-wide economic reductions.

Based on estimated replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are unknown.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater Los Angeles region and the CSU Chancellor’s Office. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU Chancellor’s Office and community.

In the event that a major earthquake were to occur along the many fault systems surrounding Long Beach, the effects could be significant to the office community and facility operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Los Angeles...
region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The facility will likely be required to address critical needs independently during early phases of the disaster.

The office population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Erosion**

**Description of the Hazard**

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.”\(^{42}\) Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

**Location of the Hazard**

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil

---

characteristics, and vegetative cover. Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. As such, for the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the CSU Chancellor’s Office campus with erosion-prone characteristics.

Extent of the Hazard
Erosion is occurring on the Pacific coastline west of the Chancellor’s Office. While there is no published scale of severity or extent for this geologic hazard at the Chancellor’s Office location, erosion is likely to occur if conditions are favorable. Given no historical occurrence of erosion on campus, the planning committee ranks the extent of this hazard as Low.

History of the Hazard
There is no record of past incidents of erosion at the Chancellor’s Office.

Potential Impacts of the Hazard
Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. Coastal erosion can result in severe impacts to local infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. At the Chancellor’s Office, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

Probability of Future Occurrence of the Hazard
Erosion is an on-going and dynamic process that occurs regularly. As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, the probability of at least a limited degree of erosion in the future is likely over the long term, though Possible on an annual basis.

Vulnerability to the Hazard
Topography, soil structure, land use, and precipitation are all factors of erosion. Chancellor’s Office infrastructure and buildings are not located on steep slopes; however, areas with little vegetation, or in areas with conducive soil types will be vulnerable to erosion.
In the wider community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on the CSU Chancellor’s Office campus. Campus leadership may choose to conduct an assessment, should modeling improvements be made.

**Vulnerability Assessment Conclusions**

While the ability to predict future erosion at the Chancellor’s Office is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

---

**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.43

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.44 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the

---

44 National Weather Service. *Discussion on Humidity.* Retrieved 01.27.21 from: https://www.weather.gov/lmk/humidity
temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.45

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.46 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.47

Location of the Hazard

Extreme heat events are a non-spatial hazard and may occur throughout the CSU Chancellor’s Office planning area.

Extent of the Hazard

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the high 70s to mid-80s in Long Beach. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at the Long Beach Daugherty Airport was 111° F on September 27, 2010. Based on extreme heat’s historical (and potential) public health impacts and power outage disruptions, and more than 85 days over 100 degrees (1980 – 2018) as reported by the NCDC and NCEI, the planning committee ranks the extent of the hazard as Moderate.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach those criteria.48 In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

45 Ibid.
Figure 27-10 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.
As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.

</tr>
</tbody>
</table>

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been five excessive heat events in Los Angeles County since 2007. These events were grouped together as part of the same heat waves.

**August 30, 2007; September 1, 2007; September 3, 2007:** A combination of high temperatures and high humidity produced an extreme heat event across Southern California. Heat index values ranged from 105° to 112° F. There were eight deaths attributable to this excessive heat event.

**June 20-21, 2008:** During this large-scale heat wave that impacted much of the state, afternoon high temperatures climbed as high as 114° F. The heat resulted in several power outages due to excessive electrical use.

The NCDC database also lists 85 additional times that the recorded temperature at the Long Beach Daugherty Airport has reached 100° F or greater between 1980 and 2018.

Potential Impacts of the Hazard

The CSU Chancellor’s Office may experience impacts from extreme heat due the strain on the utility systems.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which, in turn, threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

Based on NCDC data, 85 days of 100-degree or more temperatures have occurred since 1980 for an annual average of 2.1 events. Using the scale provided, it is **Likely** that at least 100-degree temperatures will occur annually. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. It is reasonable to assume that such an index was reached during many of the 85 recorded events since 1980. 50

Vulnerability to the Hazard

50 Hazard Mitigation Plan, City of Long Beach. *Table of Contents.* Print. Retrieved 01.27.21 from: https://www.longbeach.gov › longbeach-hazard-mitigation-plan
When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result. This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the CSU Chancellor’s Office is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three degrees on average over the last century, with less rainfall. This may lead to stronger and longer-lasting heat events, drought, and an increased risk of wildfires.

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

**Flood**

**Description of the Hazard**

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that becomes hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding represents one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, and other features may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damage. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Floods can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash
flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the waterway exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric Rivers**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive in California, they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.
These events can produce heavy amounts of precipitation creating extensive damage. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.

Figure 27-11: The Science Behind Atmospheric Rivers

Location of the Hazard

Long Beach is at the south end of the South Bay communities and at the terminus is the Los Angeles and San Gabriel Rivers. The area around Long Beach is relatively flat and sits between the Palos Verdes Hills and hills further to the east. These include the Puente and Chino Hills which provide a potential for developing water run-off during heavy precipitation events. The rivers that drain into the Pacific Ocean serve as drainages for the watersheds of the Santa Monica and San Gabriel Mountains. There are several flood retention basins and flood control channels along the base of these hills that drain towards Long Beach to protect Los Angeles and Orange County communities. The area

surrounding the office is a developed urban environment immediately adjacent to a coastal waterfront predominately consisting of commercial land uses.
The CSU Chancellor’s Office sits within a Special Flood Hazard Area (SFHA) Zone X: Area with Reduced Flood Risk Due to Levee designation on the Flood Insurance Rate Map. The Office is located on the waterfront of the Pacific Ocean at the point where the Los Angeles River drains into the ocean. The office is 5 miles west of the San Gabriel River; however, this is not a flooding factor for the office. The Los Angeles River watershed receives the majority of its water from snowfall from the Santa Monica and San Gabriel Mountains. The Los Angeles River further collects water and precipitation runoff from urban areas in the San Fernando Valley and Los Angeles Basin.

Extent of the Hazard

Access routes and critical infrastructure to the west, east, and north are located in Zone X: Area with Reduced Flood Risk Due to Levee. Even though the CSU Chancellor’s Office resides in a minimally threatened flood zone, flood events are still possible and isolated heavy precipitation events and tidal influences can still pose localized flooding hazards. This specific hazard would substantially alter the ability of the office to maintain operations. In addition, 6 Federally Declared events have occurred in LA County during
the 25-year period from 1996-2021. Based on these facts, the planning committee ranks the extent of the hazard on campus as **Moderate**.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 27-22: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>

</tr>
</tbody>
</table>
Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.

Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.

Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.

History of the Hazard

Flooding in Long Beach and the broader Los Angeles County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the CSU Chancellor’s Office.

Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on several factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
● Agricultural (crops and livestock) damages or destruction
● Environmental damage
● Prolonged periods of necessary dewatering
● Flooding erosion may alter natural drainage channels
● Societal and community impacts
● Psychological impacts of impacted populations
● Disruptions to education delivery to community
● Damage or destruction of university materials, documents, and equipment contained within the office
● Damage or destruction of university computer systems and networks
● Damaged university infrastructure
● Inability for campus operations to resume
● Reduced capacity to support or coordinate system-wide academic and student programs
● Reductions in university revenues

Additionally, individuals who were unable to evacuate in time or refused to leave may need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and place greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

Floods can occur at any time but are most common in the Los Angeles area with winter storms saturated with subtropical moisture. Flooding occurs on average every 6.1 years from heavy precipitation that could generate potential 50- or 100-year floods in the area of the CSU Chancellor’s Office. The CSU Chancellor’s Office is located within a Zone X Special Flood Hazard Area (Area with Reduced Flood Risk Due to Levee) and adjacent to the confluence of the Los Angeles River with the Pacific Ocean.

As such, the planning committee ranks the probability of future occurrence for flooding as Possible.

Vulnerability to the Hazard

The CSU Chancellor’s Office is subject to the effects of flooding resulting primarily from excessive precipitation and isolated strong storms. A more remote potential exists for severe flooding and damage on campus and surrounding residential and commercial areas of Long Beach due to tidal influences or overflow or damage to flood control systems. The flood control channels and drainage systems that surround the Long Beach area have limited storage or volume capacities and may impact access or supply routes.
The office and the staff community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the CSU Chancellor’s Office will vary depending on the severity of flooding and when the flood was to occur. Members of the office community may become trapped on the facility depending on the level of flooding occurring on surface streets. However, in region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

The CSU Chancellor’s Office is in proximity to a variety of industrial and commercial facilities in the surrounding communities including the facilities at the Port of Long Beach. When these facilities are inundated with flood water, the potential exists for chemical release and exposure to individuals from the office community. These facilities line many of the primary access routes in and out of the campus.

The Chancellor’s Office buildings and infrastructure are vulnerable to low probability and large-scale flooding. Office utilities and communication capabilities could be impacted, rendering them disabled. A flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities which might require extensive restoration or demolishing. Flood waters may result in damage to office equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain office populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Staff remaining on the facility such as those unable to evacuate would be particularly vulnerable especially those without access to adequate transportation.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damage affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the day of week, and hour in which the flooding was to occur will influence the number of people in the office and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by physical damages, loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.
Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are unknown. However, it is unlikely for flooding to cause destructive losses to the entire facility.

Vulnerability Assessment Conclusions

The campus’ primary vulnerabilities are exposed mostly by localized flooding from isolated or large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. The consequences of a low probability, widespread flood could generate disaster effects to communities including Long Beach. The campus’ proximity to the Los Angeles River and the Pacific Ocean adds a minimal degree of vulnerability for the campus.

The potential for flooding generates the potential for several cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures, while unlikely, has exponentially powerful impacts on particular segments of the office community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.
Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Hazardous Materials

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

Fixed Hazardous Materials Incident: A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

Transportation Hazardous Materials Incident: A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway, or air transport. Populations, and built and natural environments are potentially impacted.

Pipeline Incident: A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.)
requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by the California Division of Safety and Health includes guidelines related to:

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel, chemicals, hazardous waste sites and gas pipelines are located on each campus. (Please refer to the hazardous materials map identifying the location of hazardous materials on the CSU – Chancellor’s Office campus). At larger scales (beyond the campus planning area) hazardous materials are

---

located throughout Long Beach and Los Angeles County, and reflect diverse types, configurations and scales dispersed across these geographic areas.

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard. However, for the CSU – Chancellor’s Office planning committee, based on the degree of hazardous materials near the campus (see hazmat mapping), the history of hazmat events in Long Beach and near the campus, and because the assessment of risk is so complex, it is prudent to rank the extent of the hazard for the CSU – Chancellor’s Office campus as Very High and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. 60

That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located. 61

Source:
https://w3.calema.ca.gov/operational/malhaz.nsf/$defaultView?OpenView&Start=121&ExpandView

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

https://pubs.usgs.gov/pp/pp1553/pp1553c/

https://w3.calema.ca.gov/operational/malhaz.nsf/$defaultView?OpenView&Start=121&ExpandView
With regard to hazmat incidents at the CSU – Chancellor’s Office, no events have originated on site. However, according to the planning committee, toxic gas releases occur 6 or more times per year originating from the Port of Long Beach. Oil refineries nearby also off-gas toxic chemicals 6 or 7 times per year. Also, in approximately 2010, the Port produced a toxic fire from a gas release that was so prevalent that it created a toxic cloud over the Port. As a result, the Chancellor’s Office had to close all air intakes.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

In addition to the historical event impacts, the potential impacts of chemicals and toxic gases discussed here also apply to the staff and environment on the CSU – Chancellor’s Office campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose
severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natecs)**

Natural disasters, including earthquakes, floods, and wildfire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

**Probability of Future Occurrence of the Hazard**

The probability of occurrence for a hazmat release on the CSU – Chancellor’s Office campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Highly Likely because the CSU – Chancellor’s Office experiences several recurring hazmat events annually which originate at the Port and from nearby oil refineries. That said, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

**Vulnerability to the Hazard**

Hazardous materials pose a risk to the CSU – Chancellor’s Office campus. As identified by the campus planning committee and on the hazmat map, the Chancellor’s office staff and

---

operations are regularly affected by toxic gas releases from the Port and from oil refineries. In some cases, the levels of toxic air require suspension of operations, building closure and/or evacuation of the staff.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Chancellor’s Office leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

**Estimate of Potential Losses**

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

**Vulnerability Assessment Conclusions**

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including the CSU – Chancellor’s Office) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the City of Long Beach and Los Angeles County hazard mitigation plans and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Chancellor’s Office campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements,
permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

**Identified Data Limitations**

The CSU – Chancellor’s Office planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 27-14. The Chancellor’s Office is not located in or near any landslide susceptibility zones.

**Figure 27-13: Deep-Seated Landslide Susceptibility Surrounding CSU Chancellor’s Office**

---

Extent of the Hazard

In Los Angeles County, landslides are more likely to occur in the steep slopes outside of the metropolitan area and along the coastline. The San Gabriel mountains, both steep and erosive, contain steeply walled canyons above areas with high population density. When heavy rain occurs, there is significant potential for floods and landslides throughout the County, and the indirect impacts of landslides may cover an even larger geographical extent. However, because the CSU Chancellor’s Office is a significant distance from any landslide hazard zone and there is no history of landslide events on or near campus, the planning committee ranks the extent of the landslide hazard for the campus as **Low**.

History of the Hazard

FEMA has declared thirteen major disasters involving landslides, mudslides, debris flows, or mud flows in Los Angeles County since 1978. NOAA has recorded five debris flow events in the County since 2004, most of which occurred in the areas directly surrounding metropolitan Los Angeles. The 2018 mudflows in Santa Barbara / Montecito damaged 40 to 45 homes in Sun Valley and caused a vehicle to strike a natural gas pipeline, which began to leak.
Potential Impacts of the Hazard

The Chancellor’s Office may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly affect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are also often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in the San Gabriel Mountains and therefore are highly likely to occur in the future. However, the CSU Chancellor’s Office is a significant distance from any landslide hazard zone and there is no history of landslide events on or near the campus; as a result, the probability of future occurrence of the landslide hazard is considered to be Unlikely.

Vulnerability to the Hazard

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Also, any population proximal to a landslide when it occurs is vulnerable to its impacts. The Chancellor’s office does not exhibit any of the vulnerabilities identified above.

Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to the Chancellor’s Office.
Vulnerability Assessment Conclusions

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may an employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the Chancellor's Office is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.13

Power Outage

Description of the Hazard

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly populated areas like San Luis Obispo without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines. Due to the City of Long Beach’s location and that of the Chancellor’s Office, Public Safety Power Shutoffs (PSPS) due to wildfires are not a factor the campus regularly experiences.

A power outage event can interrupt day-to-day operations of the CSU Chancellor’s Office campus, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, and close restaurants around campus and outside the campus.

Additionally, a severe outage to Los Angeles County or to the City of Long Beach would directly affect the campus and the community creating social, economic, and potential health and safety impacts.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions are:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
**Demand-Side Management:** Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.

**Load Shedding:** When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

**Location of the Hazard**

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally. (Note: If the Chancellor’s Office is experiencing a power outage, there is a high probability that the City of Long Beach is experiencing a power outage, as well.)

**Extent of the Hazard**

The California Independent System Operator (CAISO) is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities. CAISO is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and
will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, as well as a history recorded outages have taken place near campus (in the City of Long Beach), the planning committee ranks the extent of the power outage hazard for the CSU Chancellor’s Office as Moderate.

History of the Hazard

The California State University Chancellor’s Office did not report experiencing any power outages in recent years.

Historically, the most consistent reason that power outages occur in the City of Long Beach is falling trees. Extremely wet weather conditions can also present a threat due to saturated soils weakening tree foundations and allowing trees to fall in high-wind winter storms.

The City of Long Beach has experienced power outages over time. Their electric utility provider, Southern California Edison (SCE) has experienced outages, which have affected the residents of Long Beach over the years. Major power outages impacting the City of Long Beach in recent years have affected a large number of residents as seen below:

- **July 18, 2015:** The City of Long Beach experienced a power outage for three days, in what is known as the worst blackout since the 1950’s. Most residents and businesses experienced this large power outage. The power outage was due to an underground electrical fire. A maintenance hole cover flew into the air, with pressurized flames and smoke shooting into the air along with it. The fire led to 4,800 homes and businesses losing power.
- **February 20, 2021:** A loss of power occurred in South Long Beach due to arcing wires touching down on some parked vehicles. Southern California Edison crews repaired the issue over several hours to de-energize the power cables. The power outage affected approximately 3,000 Long Beach residents.

Potential Impacts of the Hazard

The California State University Chancellor’s Office and the entire university system infrastructure rely on electricity for basic business and educational operations. During a widespread power failure, it may take anywhere from several hours to days to restore operations if a significant event occurs. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.
During a power outage, the CSU Chancellor’s Office cannot continue regular functions at normal levels.

**Climate Change and Energy Shortage**

Climate change is expected to bring more frequent and intense natural disasters. Over the years, what was once a disaster uncharacteristic to landscape is now occurring outside of historical areas. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City of Long Beach and Los Angeles County experience such outages. As such, the probability ranking for the Long Beach area is **Likely**. Although the Chancellor’s Office campus has not recorded power outage events, it is connected to the power grid of the surrounding community; as a result, it is prudent to assign this same ranking to the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**
Based on the data available, and in consideration of the increasing effects of climate change, the CSU Chancellor’s Office remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Office leadership would be well-advised to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to mitigate an interruption to electrical power.

**Estimate of Potential Losses**

California’s energy infrastructure is designed to cope with the state’s highly variable conditions and frequent disruptions from wildfires, storms, and floods. Generally, power outages caused by these events are short-term and limited to regional impacts. Of more concern are system-wide outages or shortages caused by a major disruption in supply or transmission.

**Vulnerability Assessment Conclusions**

The primary concern for campus leadership is that a loss of power can lead to potential hazards to staff at the CSU Chancellor’s Office. Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The vulnerable population, especially employees with physical disabilities may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors and locks and lights may impede on a disabled employee’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, offices may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

**Identified Data Limitations**

The CSU Chancellor’s Office did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.

---

**Tsunami**

**Description of the Hazard**

A tsunami is a wave triggered by any form of land displacement along the edge or bottom of an ocean or lake. Land displacement can be in the form of submarine landslides or submarine dip-slip faults. These types of faults cause ruptures that result in seafloor uplift or down-drop. This mass movement translates to a tsunami or gravity wave within the overlying water at the surface.
Tsunamis travel radially outward from the area of initiation. The size of a tsunami is proportional to the mass that moved to generate the tsunami. As a tsunami approaches the shore and the depth of the water column decreases, the energy in the wave pushes the wave crest above the water surface resulting in a larger wave height. Wave runup is the elevation above mean sea level on dry land that a tsunami reaches. Run-up is what causes inundation of coastal areas that are below the run-up height.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing severe damage to coastal development. At the shoreline, tsunamis may take the form of a fast-rising tide, a cresting wave, or a bore (a large, turbulent wall-like wave). The bore phenomenon resembles a step-like change in the water level that advances rapidly (from 10 to 60 miles per hour). The first wave is usually followed by several larger and more destructive waves.

Location of the Hazard

The campus of the CSU - Chancellor’s Office (City of Long Beach) is located in the tsunami inundation zone. See tsunami map (below) with campus location identified within the zone. Also, see the tsunami inundation zone map for the City of Long Beach for the larger geographic range of the coastal inundation area.

Figure 27-14: Tsunami Line near Chancellor’s Office
Extent of the Hazard:

The factors shaping the extent or severity of the hazard are a combination of geophysical forces (the amount of vertical and horizontal motion of the sea floor, the area over which it occurs, and the efficiency with which energy is transferred from the earth’s crust to the ocean water) and the geographic range of coastal development to be impacted.

More specifically, as a tsunami approaches the shore, wave *run-up* is the elevation above mean sea level on dry land that a tsunami reaches. A tsunami’s potential severity can be forecasted as a function of the wave’s mass along with the difference between the wave’s run-up height and the ground elevation of the affected coastal location.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at
great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height. 66

Given the historical occurrence of tsunamis in Southern California (including Long Beach), and the catastrophic potential impact due to the Chancellor’s Office location within the tsunami inundation zone, with a maximum potential run-up height of 42 feet, the CDSU planning committee ranks the extent of the hazard as High.

History of the Hazard

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. That said, no tsunamis have impacted CSU campus locations.

According to the National Centers for Environmental Information (NCEI), have been eight tsunamis have caused damage to ports and harbors or coastal inundation in California since 1946. The most significant events are as follows:

- In 1964, a tsunami caused by a Magnitude 9.2 earthquake offshore from Alaska resulted in 13 deaths in California and destroyed portions of downtown Crescent City.
- A 2006 tsunami (originating in the Kuril Islands region north of Japan) caused approximately $20 million in damage to Crescent City harbor.
- A 2010 tsunami (originating offshore from Chile) caused millions of dollars in damage to ports and harbors in the state.
- A tsunami in 2011 (caused by a Magnitude 9.0 earthquake offshore of Japan) killed one person at the mouth of the Klamath River and caused up to $100 million of damage to 27 ports, harbors, and marinas throughout the State. The most damage occurred in Crescent City, Santa Cruz and Moss Landing harbors and a federal disaster was declared in Del Norte, Santa Cruz, and Monterey Counties. Both Crescent City and Santa Cruz harbors sustained damage to all docks, and oil spills and water/sediment contamination that resulted from sunk or damaged boats. Because recovery efforts in these two harbors took several years to complete, both harbors incurred business/economic losses that have been difficult to recapture.

In addition, the Worldwide Tsunami Database, www.ngdc.noaa.gov provides information on tsunami run-up levels and earthquake magnitude factors. Although data for the most recent events is not available, additional (earlier) tsunami events are recorded.

* The City of Long Beach has not been impacted by a tsunami previously, according to the 2016 City of Long Beach Hazard Mitigation Plan. That said, a tsunami event is recorded (above) in 1933, though the run-up height of 0.1 meters or 4 inches, so it is understandable that no event was observed on the ground.

### Potential Impacts of the Hazard

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing total devastation to coastal development.

The configuration of the coastline, the shape of the ocean floor, and the characteristics of advancing waves play important roles in the destructiveness of the waves. Bays, sounds, inlets, rivers, streams, offshore canyons, islands, and flood control channels may cause various effects that alter the level of damage. Offshore canyons can focus tsunami wave energy, and islands can filter the energy. It has been estimated that a tsunami wave entering a flood control channel could reach a mile or more inland, especially if it enters at high tide. The orientation of the coastline determines whether the waves strike head-on or are refracted from other parts of the coastline.
Potential impacts to the campus of the CSU – Chancellor’s Office in Long Beach include destruction of campus buildings and infrastructure, destruction of the natural environment, destruction of boats and coastal development, and loss of life in the area surrounding the campus. Tsunamis that impact both harbors and communities also can produce free-floating debris hazards and environmental contamination from chemical spills.

Probability of Future Occurrence of the Hazard:

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. If we consider historical occurrence as one data set for estimating future events, the average rate of occurrence over the past 150 years is 1 tsunami every 1.9 years statewide. Currently, no analysis is available which differentiates this statewide probability specifically for Long Beach, CA. Although 1 event is registered for Long Beach and 6 events for the Southern CA region, it is prudent to utilize the 1.9-year recurrence internal for planning purposes given extreme difficulties predicting tsunami points of origin. As such, the planning committee ranks the annual probability of a tsunami for the campus as Possible.

That said, the rate of future occurrence may change and may be able to make target estimates for specific locations in the future; the California State Tsunami Program is trying to refine the accuracy of the data. In doing so, the State Tsunami Program is completing a set of Probabilistic Tsunami Hazard Analysis (PTHA) maps representing risk levels from 100-year to 3000-year average return periods. Analysis using these probabilistically based products will allow for a more common platform for comparison to other seismic and flood probabilistic analyses. 67

Vulnerability to the Hazard

With regard to CSU campus locations, direct vulnerability of assets and people to tsunami only applies to Humboldt State University in Arcata CA, and the CSU Chancellor’s Office in Long Beach, CA, as these are the only 2 campuses located in a mapped tsunami zone.

Regarding the vulnerabilities for the Chancellor’s Office location, the greatest vulnerability are properties located near Oceanfront and the Port of Long Beach. Tsunami “maximum run-up” projections were modeled by the University of Southern California and distributed by the California Office of Emergency Services for the purposes of identifying tsunami hazards. The tsunami model was the result of a combination of inundation modeling and onsite surveys and determined the maximum projected inundation levels from tsunamis along the entire coast of Los Angeles County.

67 2018 State of California Hazard Mitigation Plan
The maximum run-up for is approximately 42 feet. This means that based on the worst-case scenario tsunami, the displaced water level would be approximately 42 feet above the normal tide for that day and time. As such, given that the Chancellor’s Office is located on the oceanfront, it is vulnerable to catastrophic loss, as are any staff or visitors unable to evacuate with proper lead-time.68

Population Vulnerability
The populations most vulnerable to the tsunami hazard are the elderly, disabled and very young who reside near beaches, low-lying coastal areas, tidal flats and river deltas that empty into ocean going waters. In the event of a local tsunami generated near the coast, little warning time would exist, so more of the population would be vulnerable, and to some extent, this vulnerability pertains to the Chancellor’s Office location in Long Beach. Though no data is currently available for Long Beach, it is densely populated which creates a high degree of vulnerability.

Property Vulnerability
The impact of tsunami waves and the scouring associated with debris that may be carried in the water could be damaging to all structures along beaches, low-lying coastal areas, tidal flats and river deltas. The most vulnerable structures are those in the front line of tsunami impact and those that are structurally unsound. According to the 2018 State of California Hazard Mitigation Plan, Long Beach exhibits among the state’s highest number of businesses located in the tsunami zone.

Critical Facilities and Infrastructure
The following infrastructure is vulnerable to damage in Long Beach, CA:

- Water Proximate Infrastructure—Breakwaters and piers collapse, sometimes because of scouring actions that sweep away their foundation material and sometimes because of the sheer impact of the tsunami waves.
- Flood Control Systems—Floodwaters can back up drainage systems, causing localized flooding. Culverts can be blocked by debris from tsunami events, also causing localized urban flooding.
- Utility Systems—Floodwaters can get into drinking water supplies, causing contamination. Sewer systems can be backed up, causing waste to spill into homes, neighborhoods, rivers and streams. Tsunami waves can knock down power lines and radio/cellular communication towers. Power generation facilities can be severely impacted by wave action and by inundation from floodwater.
- Fuels—Destruction of fueling infrastructure and related environmental and potable water contamination can occur.

68 2016 City of Long Beach Hazard Mitigation Plan.
Estimates of potential losses specific to CSU campuses have not been conducted yet. In addition, no estimated loss data is currently available for the City of Long Beach, although the local mitigation plan indicates concern for losses related to fires from damaged ships in ports or from ruptured coastal oil storage tanks and refinery facilities in the port area. That said, according to the State plan, technological improvements have been made in the ability to estimate losses from tsunami impacts which can be brought to bear on loss estimation for CSU campuses in the future.

Vulnerability Assessment Conclusions:

According to the 2018 State of California Hazard Mitigation Plan, community exposure to tsunamis in California varies considerably—some communities may experience great losses that reflect only a small part of their community and others may experience relatively small losses that devastate them. Among the 94 incorporated communities and 83 unincorporated areas of the 20 coastal counties, the communities of Alameda, Oakland, Long Beach, Los Angeles, Huntington Beach, and San Diego have the highest number of people and businesses in the tsunami inundation zone.

For improving assessments of vulnerability, FEMA has developed a new tsunami loss estimation module for HAZUS using existing numerical model results for tsunami inundation, flow depth, velocity, and force. This HAZUS module allows new capability for estimation of economic losses, and site-specific analysis of content losses, casualties, infrastructure damage, and evacuation time. The module calibrates losses based on safe zones and community preparedness levels. Such technological improvements in assessment capability can be utilized for tsunami hazard analysis and planning purposes for the CSU Chancellor’s Office.

Along with new probability-based tsunami maps, the HAZUS module will improve the ability to compare tsunami impacts to those of other hazards. Moreover, the probability mapping will be used for numerous applications including identifying potential tsunami hazard “zones of required investigation” under the Seismic Hazards Mapping Act and will assist state and local agencies in making land use planning decisions. They will also help regional and state planners understand the flood potential from tsunamis representing different risk levels. The improved analysis and data will be utilized by the SU Chancellor’s Office through its partnerships with key stakeholder organizations.69

**Note:** To download the Community Exposure to Tsunami Hazards in California report visit the USGS website: http://pubs.usgs.gov/sir/2012/5222/.

69 2018 State of California Hazard Mitigation Plan
Identified Data Limitations

As identified in the vulnerability conclusions (above), with regard to the current planning effort, the primary data limitations for assessing the tsunami hazard for CSU campuses (Chancellor’s Office and Humboldt State University) are comprehensive asset valuations lying within the tsunami inundation zone, and the need to apply FEMA’s new probability mapping techniques and tsunami loss estimation module to the footprint of each campus. That said, CSU leadership and planning teams intend to pursue such data in the future.

Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of Los Angeles County is located within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of kilometers.

---

miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While the Chancellor’s Office does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the office. As such, the planning committee ranks the extent of the hazard for the campus as **Low**.

**History of the Hazard**

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

**Potential Impacts of the Hazard**

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As the Chancellor’s Office is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at the Chancellor’s Office.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

**Probability of Future Occurrence of the Hazard**

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as **Unlikely**.
Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For the Chancellor’s Office, there is low vulnerability to the immediate impact of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

The Chancellor’s Office is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This fact, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in structural loss, infrastructure loss, dangerous air quality, environmental damage, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents the greatest risk to human life and property.
Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population creates a combination of factors that promote an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially influence the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience

---

decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

Location of the Hazard

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. CSU Chancellor’s Office and the City of Long Beach are located in the southern end of the Los Angeles Basin along the coast. This area near the Chancellor’s Office is dominated by urban and coastal communities with limited to no direct exposures to wildland fire and the campus is not located within any Fire Hazard Severity Zones.

The CSU Chancellor’s Office is located in the southern side of Long Beach along the waterfront of the confluence of the Los Angeles River and the Pacific Ocean. The office is 7 miles east of the closest area designated as having a high fire hazard in the Palos Verdes Peninsula where there is a mix of residential neighborhoods and hillsides with moderate vegetative fuels.

However, the CSU Chancellor’s Office is surrounded by mountain ranges hosting three national forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the basin in the right wind conditions. The geography of the Los Angeles Basin and San Gabriel, San Fernando, and San Bernardino valleys creates a topography that captures air pollutants including smoke and the CSU Chancellor’s Office is located in a region in which wildfire smoke can saturate the air around the facility.
Figure 27-16: Fire Hazard Severity Zones

Extent of the Hazard

While the threat to fire directly affecting the campus is minimal, the direct effect of fire generated smoke might occur. Fires are likely to occur in areas close enough to the campus that generate substantial amounts of smoke that could envelop the campus in the right atmospheric conditions. Fires that are large enough to generate volumes of smoke to cover great distances have the potential to affect the air quality of the Los Angeles County area including the campus. This will especially be the case in weather conditions creating strong offshore winds. The potential for this impact has been demonstrated during the summers of 2018, 2019, and 2020 as fires burned across the state and spread smoke over vast distances. Fires burning outside of the Los Angeles County region have the potential to distribute smoke onto the CSU Chancellor’s Office.

Given that the area immediately surrounding the Chancellor’s Office is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones, and the campus does not have a history of wildfire activity occurring within proximity to the campus, it nevertheless has experienced impacts to air quality from smoke. Therefore, the planning committee ranks the extent of the hazard as Low to Moderate.

Moreover, as a large number of wildfires are ignited due to human caused factors, the ability to determine when or where a wildfire might occur is impossible. Only the conditions for a wildfire can be predicted with any accuracy.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions. The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 27-26: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common.</td>
</tr>
</tbody>
</table>

### COLOR CODE: Yellow

<table>
<thead>
<tr>
<th>CLASS 4: Very High Danger (VH)</th>
<th>High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Orange</td>
<td>Fires start very easily and spread at a very fast rate. Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</td>
</tr>
<tr>
<td>COLOR CODE: Red</td>
<td>Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</td>
</tr>
</tbody>
</table>

Agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke.

The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposure to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Los Angeles County also has a long history of wildfire activity primarily in the foothills and mountains of the San Gabriel and Santa Monica Mountains. Wildfires occurring in Los Angeles County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damage.

The area immediately surrounding the CSU Chancellor’s Office is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The office does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Long Beach Chancellor’s Office has experienced multiple days of poor air quality due to fires burning in Los Angeles, Orange, Riverside, and San Bernardino Counties. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Los Angeles County. CSU Chancellor’s Office personnel reported the ongoing development of procedures to address the response to poor air quality days.

Potential Impacts of the Hazard

The CSU Chancellor’s Office is surrounded by areas of urban development and water removed from areas with a fire hazard places a minimal direct threat from wildfire to the office. The potential impacts of wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable

\(^{77}\) 2019 Los Angeles County All-Hazards Mitigation Plan, 2019
• Psychological impacts of impacted populations
• Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

• Dangerous levels of air pollution
• Human Health Effects
  • Similar health impacts to pets
• Air conditioning systems overwhelmed
• Greater demands on air filtration systems
• Greater demands on healthcare systems
• Reduced outdoor work productivity
• Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Los Angeles County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds may cause future landslides, degradation to plants supporting hillsides, and impact hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the minimal wildfire threat potential in the area surrounding the CSU Chancellor’s Office, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered **Unlikely**.

Based on the wildfire threat potential in the area surrounding Southern California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered **Possible**.

Vulnerability to the Hazard

The CSU Chancellor’s Office is not likely to be subject to direct impact from wildfire due to the campus location in an urban/waterfront area of Long Beach. The vulnerabilities to the effects of wildfire would largely lie within the office community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of Long Beach. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the office in the form of needed assistance or facility support to emergency resources.
Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or open areas surrounding the city. These incidents would likely have little impact to the office.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

Some areas of particular vulnerability on the campus include:

- Staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC or do not have HVAC will cause limitations in filtering of air during smoke filled days
- Power outages or brownouts during days with high levels of smoke will limit shelter in place options during heat events in summer.
- Santa Ana wind events may push large volumes of smoke into the Los Angeles Basin

The greater concerns regarding vulnerabilities to wildfire on CSU Chancellor’s Office are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Los Angeles Basin even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Chancellor’s Office personnel both on the facility and off the facility face these same vulnerabilities related to smoke filled air.

Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Staff participating in outdoor tasks including aerobic activities are increasingly vulnerable to the effects of wildfire which will vary depending on when the air quality were to reach unhealthy levels. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the office community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the office enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses
Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are unknown. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher. However, the location of the campus in an urban/suburban setting removed from hazard prone areas makes wildfire related damages unlikely.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Los Angeles County; however, wildfire incidents do not pose a direct risk to the CSU Chancellor’s Office. The location of the CSU Chancellor’s Office, surrounded by densely developed commercial and industrial land uses adjacent to ocean waterfront, mitigates any vulnerabilities of wildfire hazards to the office community or facilities.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the office community. The staff of CSU Chancellor’s Office who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the office. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential
for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.

Additionally, the topography of Southern California surrounded by mountains allows for smoke filled air to linger in the valleys of the Los Angeles Basin with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains generating tremendous quantities of smoke present tremendous health related vulnerabilities to members of the office community. The office community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Severe Weather (Wind, Tornado, Hail, and Lightning)

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

---

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including the CSU Chancellor’s Office.

**Regional Climate Influences on Severe Weather across California**

---

80 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat

83 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino

Most of the weather in California is influenced by the wet-winter/dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.85

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including the CSU Chancellor’s Office), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada and occur with greater frequency during the summer months.86

**Types of Storms in California**

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.87 The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.88 These storms affect (in varying degrees) all CSU campuses, including the CSU Chancellor’s Office.

- **Thunderstorm:** A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including

---

85 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
86 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
tornadoes, hail, strong winds, lightning and flooding. Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. Severe thunderstorms are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.

- **Hailstorm:** a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.
- **Wind storm:** marked by high wind with little or no precipitation.
- **Winter storm:** A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.
- **Coastal storm:** large wind-driven waves and/or storm surge that strike the coastal zone.
- **Ice storm:** Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is

---

92 Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

93 Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm

required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.98

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.99

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: **wind hazards (including tornadoes), hail, and lightning**. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.100 Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”101

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including the CSU Chancellor’s Office).

**High Winds, Strong Winds, and Thunderstorm Winds**

---

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.102

**Strong Winds**

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.103

**Thunderstorm Winds**

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.104

Please note: *Straight-line wind* is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.105 However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

**Tornadoes**

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.106 This column extends between clouds and the Earth’s surface. The damaging power from tornadoes comes from intense winds and flying debris. It is believed that rotational wind speeds can

---

106 Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/
be as high as 300 mph in the most violent tornadoes.\textsuperscript{107} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{108}

\textbf{Santa Ana Winds}. A type of wind hazard that is peculiar to Southern California is called a \textit{Santa Ana Wind}. Santa Ana winds are strong, topographically enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{109} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{110} (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

\textsuperscript{107} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/

\textsuperscript{108} Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions

**What Drives a Santa Ana Wind?**

1. High surface pressure builds over the Great Basin region with lower pressure off Southern Cal Coast. (Fall-mid Spring)

2. Air remains relatively cold across the deserts. As the air extends through the mountain passes...it become compressed and warms. (See lower right map) Lower relative humidity also occurs helping to dry out vegetation and can fan any existing fires.

3. Wind speed increases as it squeezes through the mountain and valley canyons. Wind gusts can vary from 45 to 100 mph depending on the strength of the Santa Ana event.

4. Strong winds create turbulence for area flights and can make interstate travel difficult as well as choppy seas for mariners.

**Cross Section over the Los Angeles and Ventura County Mountains to the Pacific Ocean**

Source: National Weather Service

---

**Diablo Winds.** The Diablo wind is another type of topographically enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.¹¹²

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining

---

narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.113 114 115

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.116 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.117

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.118

---

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{119} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the CSU Chancellor’s Office campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all of the CSU Chancellor’s Office campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to the CSU Chancellor’s Office reflect those of the surrounding community and County. As a result, all assets and people at the CSU Chancellor’s Office are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Long Beach area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as Moderate. See each sub-hazard below for the planning committee’s sub-type extent ranking.

*Wind Hazard: Non-Rotational*

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.\textsuperscript{120} First developed in 1805, it is still used today to estimate wind strengths.\textsuperscript{121}

\textsuperscript{120} Retrieved on 07.15.2021 from https://www.rmets.org/resource/beaufort-scale

\textsuperscript{121} Retrieved on 07.15.2021 from https://www.weather.gov/mfl/beaufort

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **Moderate.**
Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale. In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind *estimates* (not measurements) based on damage.

It is important to note the *date* that a tornado occurred. Tornadoes that occurred prior to February 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

The Table below illustrates the Fujita Scale in use prior to February 2007.

Table below illustrates the Enhanced Fujita (EF) Scale, currently in use. Tornadoes that have occurred since February, 2007 are classified using the Enhanced Fujita Scale.
**Table 27-31: Enhanced Fujita Scale (February 2007 and Later)**

<table>
<thead>
<tr>
<th>Enhanced Fujita Category</th>
<th>Wind Speed</th>
<th>Potential Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>EF0</td>
<td>65-85 mph</td>
<td>Light damage. Peels surface off some roofs; some damage to gutters or siding; branches broken off trees; shallow-rooted trees pushed over.</td>
</tr>
<tr>
<td>EF1</td>
<td>86-110 mph</td>
<td>Moderate damage. Roofs severely stripped; mobile homes overturned or badly damaged; loss of exterior doors; windows and other glass broken.</td>
</tr>
<tr>
<td>EF2</td>
<td>111-135 mph</td>
<td>Considerable damage. Roofs torn off well-constructed houses; foundations of frame homes shifted; mobile homes completely destroyed; large trees snapped or uprooted; light-object missiles generated; cars lifted off ground.</td>
</tr>
<tr>
<td>EF3</td>
<td>136-165 mph</td>
<td>Severe damage. Entire stories of well-constructed houses destroyed; severe damage to large buildings such as shopping malls; trains overturned; trees debarked; heavy cars lifted off the ground and thrown; structures with weak foundations blown away some distance.</td>
</tr>
<tr>
<td>EF4</td>
<td>166-200 mph</td>
<td>Devastating damage. Well-constructed houses and whole frame houses completely levelled; cars thrown and small missiles generated.</td>
</tr>
<tr>
<td>EF5</td>
<td>&gt;200 mph</td>
<td>Incredible damage. Strong frame houses levelled off foundations and swept away; automobile-sized missiles fly through the air in excess of 100 m (107 yd); high-rise buildings have significant structural deformation; incredible phenomena will occur.</td>
</tr>
</tbody>
</table>

---

Based on the extent ranking factors identified (above), the planning committee ranks the extent of tornados as **Low**.

**Extent: Hail**

The National Oceanic and Atmospheric Administration and the Tornado and Storm Research Organization (TORRO) have combined efforts to create the Hailstorm Intensity Scale. Table below provides details of this scale.

Table 27-32: Combined NOAA/TORRO Hailstorm Intensity Scale

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the hail hazard as **LOW**.
Extent: Lightning

The National Weather Service (NWS) uses a Lightning Activity Level (LAL) scale to indicate the frequency and character of cloud-to-ground (C/G) lightning. The scale uses a range of 1 – 6, with 6 being the high end of the scale. The Table below provides details of the LAL scale.

Table 27-33: Lightning Activity Level (LAL) Scale\textsuperscript{127}

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **Low**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms.\textsuperscript{128} \textsuperscript{129} That said, according to the \textit{Glossary of Meteorology} published by the American Meteorological Society (AMS), a thunderstorm is reported as \textit{light, medium, or heavy} according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds;
- the effect upon surface temperature.\textsuperscript{130}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- \textbf{Airmass Thunderstorm}: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{131}

- \textbf{Frontal Thunderstorm}: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{132} or

- \textbf{Squall-line Thunderstorm}: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\textsuperscript{133} \textsuperscript{134}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as \textbf{Low}.

\textbf{History of the Hazard}

\textsuperscript{128} Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
\textsuperscript{129} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
Severe weather hazards have been an annual occurrence in Los Angeles County and on the CSU Chancellor’s Office campus. Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\(^{135}\) For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\(^{136}\) To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus, to some degree, experiences those severe weather events reported for the surrounding community and County.

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Los Angeles County since 1996.\(^{137}\) Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\(^{138}\)

- **High Wind**: at least 387 events, or approximately 15.28 events per year\(^{139}\)

\(^{139}\) National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=LOS%2BANGELES%3A37&hailfilter=0.00&tornfilter=0.00&windfilter=0.00&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA
- **Strong Wind:** at least 3 events, or 0.12 events per year\(^{140}\)
- **Thunderstorm Wind:** at least 43 events, or approximately 1.70 events per year\(^{141}\)
- **All Wind Hazard events** (excluding Tornadoes): at least 427 events, or approximately 16.86 events per year.\(^{142}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Los Angeles County, there have been at least 427 wind hazard events since 1996, excluding tornadoes.\(^{143}\) That translates to an approximate average historical frequency of occurrence of **16.86** wind hazard events per year.

Please note: Differences between the sums of individual component wind hazard event Database searches (i.e., 433 events) and simultaneous Database searches of all wind hazard events (i.e., 427 events) are due to multiple event types in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado").\(^{144}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 427 events) is used to determine the historical frequency of occurrence for the severe weather hazard.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 433 events) and simultaneous Database searches of all severe weather hazard events (i.e., 427 events) may be due to the following factors: (1)

multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Los Angeles County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County. When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 427 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Los Angeles County has experienced since 1996 have been costly. There have been 2 deaths and 4 injuries reported from wind hazard events (excluding tornadoes) in Los Angeles County; no property or crop damage has been reported.

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 12 reported events of tornadoes in Los Angeles County, which translates to approximately 0.47 tornado events per year.

The vast majority of tornado reports in Los Angeles County since 1996 have been of tornadoes with a severity rating of F0/EF0. Only one (1) or 12 of the tornadoes reported in has been rated F1/EF1 or higher (it was an F1 tornado that occurred in 1998); that translates to approximately 0.04 events of F1/EF1 tornadoes have occurred per year in Los Angeles County.

**Historical Tornado Hazard Losses for Los Angeles County since 1996**

148 National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=LOS%2BANGELES%3A37&hailfilter=0.00&tornfilter=0.00&windfilter=0.00&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA
According to the NCEI Storm Events Database, the tornado hazard events that Los Angeles County has experienced since 1996 have been minimal. There have been no deaths, or property or crop damage reported; however, one (1) injury has been reported.\(^{149}\) (Note: An F1/EF1 tornado that occurred in Los Angeles County in 1998 caused the one (1) reported injury.)

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 18 reported events of hail in Los Angeles County, which translates to approximately 0.71 hail events per year.\(^{150}\) (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 19 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, over 100 miles away from Los Angeles County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Los Angeles County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damage, property damage estimates have totaled approximately $3,500,000; the property damage estimate reflects one (1) hail hazard event that occurred in 2003.\(^{151}\) (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Los Angeles County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 9 reported events of lightning in Los Angeles County, which translates to approximately 0.36 lightning events per year.\(^{152}\)

Historical Lightning Hazard Losses for Los Angeles County since 1996

According to the NCEI Storm Events Database, the lightning hazard events that Los Angeles County has experienced since 1996 have been costly. While no property or crop damage has been reported, there have been 2 deaths and 13 injuries attributed to lightning hazard events.153

All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database

Information obtained from the NCEI Storm Events Database indicates that there have been 466 occurrences of the severe weather hazard in Los Angeles County. This translates to 18.39 severe weather hazard occurrences per year.154

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 473 events) and simultaneous Database searches of all severe weather hazard events (i.e., 466 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Los Angeles County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.155

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 466 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical, Aggregated Severe Hazard Losses for Los Angeles County since 1996

According to the NCEI Storm Events Database, the severe weather events that Los Angeles County has experienced since 1996 have been costly. There have been 4 deaths and 18 injuries, and property damage estimates have totaled approximately $3,500,000; no crop damage has been reported. It is important to note that for all Los Angeles County severe weather hazard events recorded on the Storm Events Database, lightning has

accounted for half of the deaths, and 13 out of 14 (92.9%) injuries reported. However, hail has accounted for all estimated property damage.

Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April.\textsuperscript{156} From 1948 to 2012, a total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{157 158}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Figure 27-19: Mean Annual Frequency of Santa Ana Wind events (1948-2012)\textsuperscript{159 160}

Diablo Winds

Diablo wind events occur approximately *2.5 events per year*. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^\text{161}\)

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.162

Figure 27-20: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)163

**Sundowner Winds**

Strong sundowner wind events occur approximately **2-3 times per year**. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.164

**Historical Frequency of All Severe Weather Hazards**

Table below shows the average historical frequency of severe weather hazard events for Los Angeles County since 1996.)

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within the CSU Chancellor’s Office campus areas are at risk from the effects of severe weather.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU Chancellor’s Office campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.
According to the 2017 City of Long Beach Hazard Mitigation Plan Local Hazard, the “Windstorm” hazard (i.e., high wind, including tornado, that is primarily caused by Santa Ana winds) is a hazard that poses enough of a “significant” threat to the city that it could result in the declaration of a local disaster. On a scale of 1 (lowest) to 4 (highest), it is rated as 2.95 (out of 4) in terms of significance. As a result, the wind hazard is considered to be of medium to high significance, and therefore to have a moderate to high potential impact on both the city and (by extension) the CSU Chancellor’s Office campus. 165

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

According to the 2017 City of Long Beach Hazard Mitigation Plan Local Hazard, hail hazards are not considered to be significant hazards, and are therefore not included in the hazards profiled by the Plan. As a result, the hail hazard is deemed to have low significance, and therefore to have a minimal potential impact on both the city and (by extension) the CSU Chancellor’s Office campus. 166

**Lightning**

Lightning strikes the United States about 20-25 million times a year. 167 Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured. 168 Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year. 169 (Commercial claim payouts for lightning losses for the U.S. were not available.)

According to the 2017 City of Long Beach Hazard Mitigation Plan Local Hazard, the lightning hazard is not considered to be significant hazard, and therefore is not included in the hazards profiled by the Plan. As a result, the lightning hazard is deemed to have

---

low significance, and therefore has a minimal potential impact on both the city and (by extension) the CSU Chancellor’s Office campus.\textsuperscript{170}

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The 2017 City of Long Beach Hazard Mitigation Plan states that the probability of “Windstorm” events (i.e., high wind events – including tornadoes – caused primarily by Santa Ana winds) occurring in Long Beach is “Highly Likely;” that is, they are frequent events with a well-documented history of occurrence and an annual probability of greater than 1 in 10 (>10%).\textsuperscript{171} Also, according to the NCEI Storm Events Database, severe weather wind hazard events (excluding tornadoes) have occurred in Los Angeles County 427 times since 1996, or an average of 16.86 times per year.\textsuperscript{172} Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Chancellor’s Office campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU Chancellor’s Office campus reflect those of the surrounding community and County identified in Table below.

Based on the data available from both the 2017 City of Long Beach Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU Chancellor’s Office campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU Chancellor’s Office is **Highly Likely**. See Table 27-XX for probabilities of future occurrence for component severe weather hazards for the Los Angeles County and the campus.

Vulnerability to the Hazard

People, structures, and assets on the CSU Chancellor’s Office campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The CSU Chancellor’s Office campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire CSU Chancellor’s Office campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within the CSU Chancellor’s Office campus are at risk from severe weather. There is only one (1) building on the CSU Chancellor’s campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. Unfortunately, the total replacement costs due to severe weather hazard are unknown, as estimated
campus facility and structure values for the CSU Chancellor’s Office were not available. Moreover, an analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at the CSU Chancellor’s Office campus varies throughout the day. As of Fall, 2019, the CSU Chancellor’s Office had 673 administrators and staff.\textsuperscript{173} All are at risk from severe weather events, with all 673 Chancellor’s Office employees being directly vulnerable in this scenario.\textsuperscript{174}

**Vulnerability Assessment Conclusions**

Severe weather presents a variety of hazards to the CSU Chancellor’s Office campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to the CSU Chancellor’s Office.

It is evident that the CSU Chancellor’s Office campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

**Identified Data Limitations**

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.
