Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.

Figure 14-14: Air Quality Index for Ozone and Particulate Pollution\(^63\)

---

\(^63\) AirNow. *Air Quality Index (AQI) Basics.* Retrieved 05.05.2021 from: [https://www.airnow.gov/qaq/aqi-basics/](https://www.airnow.gov/qaq/aqi-basics/)
History of the Hazard

Wildfire events are of major concern to Solano County fire districts and residents. Since 1952, 90 wildfire events have occurred in the unincorporated areas of Solano County. These events range from 6 acres to more than 30,000 acres (CAL FIRE 2011). Of these documented occurrences, two were more than 30,000 acres. The first, known as the Atlas Peak wildfire, caused $36 million in damage and destroyed 65 structures, 39 near Atlas Peak, 16 on Soda Canyon Road, and one on Silverado Trail. Though the Atlas Peak fire was mostly in Napa County, parts of the fire spread into Solano County. No one was killed in the blaze and the cause of the fire was arson (Napa Valley Register 2006). The second, known as the Miller Canyon wildfire, took place in 1988. Nine homes, three outbuildings and $7 million worth of telecommunications equipment were burned. Transmission equipment owned by MCI, AT&T, PG&E, Pacific Bell, and several local government agencies was damaged (Los Angeles Times 1988). The Miller Canyon wildfire event caused by arson, burned 34,564 acres, was declared a FEMA Presidential Disaster (FEMA-DR-815) was enacted as a result of the damage.

Most recently, in 2008, the “Wild” wildfire event burned 4,102 acres due to arson. The wildfire event ignited near Wild Horse Valley Road in Napa County, spreading through dry grass, oak trees, and brush toward the area of Lake Madigan in Solano County (CAL FIRE 2011). One of the last major wildfire occurrences in unincorporated Solano County was the 2011 Beacon Fire. The Beacon Wildfire burned more than 700 acres and threatened 40 homes at the northeastern edge of the City of Fairfield.
In 2019, Cal Maritime suffered property losses when a wildfire jumped Interstate 80 in Vallejo and entered the campus, destroying a maintenance building, storage containers, vehicles, equipment, and trees. (There were no injuries.)

Potential Impacts of the Hazard

Because the location of the Cal Maritime campus is removed from areas designated as high fire hazard severity zones, the threat of flame, ember, and smoke exposure from wildfire to the campus is minimized. However, there are hillsides with a history of fires occurring within proximity to the campus. There is potential for fire to occur from north and east of the campus. The surrounding hillsides and valleys are composed of light to moderate fuels. The threat from fire and the impacts fire would have on the university is due to the campus being located adjacent to open hillsides and field susceptible to fire spread.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Threat or damage to power plant
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations

---

- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
- Similar health impacts to pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Solano County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the wildfire threat potential in the area on and surrounding the Cal Maritime campus, including the immediate proximity to hillsides with extensive vegetative growth, and the historic occurrences of fires, the probability of wildfire related damage and impacts from smoke is considered Possible.

Based on the wildfire threat potential in the area surrounding the campus and the San Francisco North Bay region, including the volume of areas in elevated Fire Hazard Severity Zones throughout the Solano and Contra Costa Counties, the past occurrences of wildfire generated smoke from areas beyond Solano County, the probability of wildfire generated smoke impacts to air quality is considered Possible.

Vulnerability to the Hazard

The Cal Maritime campus is not identified to reside in a designated local High or Very High Fire Hazard Severity Zone. However, the campus is subject to direct impact from wildfire due to the campus location within a wildland-urban interface zone. The
The campus is bordered on two sides by hillsides and open lands containing combustible vegetation combined with residential development and a history of wildfires. Additionally, vulnerabilities to the effects of wildfire pertain to any members of the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillsides and extending onto the campus or localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have a significant impact on the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures. Structures with vegetation and other combustibles near the structure increase the ability of fire to spread to buildings.

Access to the north using Sonoma Blvd or Maritime Academy Drive servicing access to Vallejo and Interstate 80 could become cutoff during fire incidents. Country Lane Road exiting the back of campus may also be impacted by fire, making it impassable. The university is limited by these routes for access to and from the campus. Access for supplies, equipment, and emergency services in addition to evacuation away from the campus would likely be forced to use alternative routes into Vallejo.

The greater concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Bay Area even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. Cal Maritime students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.
The vulnerability to members of the campus community in which wildfire generated smoke on the Cal Maritime campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $83,596,545. However due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Solano County, including wildfire incidents that have threatened the Cal Maritime campus. The location of the
Cal Maritime campus exposed to open hillsides with light to moderate vegetative fuels along the eastern edges presents a threat of fire to the campus community and campus assets. These environments are ideal for the development of wildfire activity in the right conditions. The consequences of fires in these areas would present primary and secondary consequences to the Cal Maritime campuses and expose vulnerabilities on the campus and to the campus community.

The topography and weather conditions of the region allows for smoke filled air to linger in the valleys of San Francisco Bay Area with the potential for unhealthy air quality depending on wind conditions. Large fires burning from even far away locations in northern California have demonstrated to fill expansive areas with smoke filled air.

Communities located within or near the Wildland Urban Interface throughout the Bay Area may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, and homeless students.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Severe Weather (Wind, Tornado, Hail, Lightning)

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, heat waves, extreme rainfall, unusual cold temperatures) needs to be rare or extreme.

lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but

70 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU Maritime Academy (Cal Maritime).

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including Cal Maritime), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage. The SHMP also lists the following types of storms that produce hazardous conditions and potential damage:

72 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
73 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
throughout the state of California. These storms affect (in varying degrees) all CSU campuses, including Cal Maritime.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. *Severe thunderstorms* are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.

- **Wind storm**: marked by high wind with little or no precipitation.

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a

---

79 Retrieved on 07.15.2021 from [https://www.weather.gov/safety/thunderstorm](https://www.weather.gov/safety/thunderstorm)

80 Retrieved on 07.15.2021 from [https://www.weather.gov/safety/thunderstorm](https://www.weather.gov/safety/thunderstorm)

glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\(^85\)

- **Snowstorm:** A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\(^86\)

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: **wind hazards** (including tornadoes), **hail**, and **lightning**. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\(^87\) Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”\(^88\)

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including Cal Maritime).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are

---

used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\(^8^9\)

**Strong Winds**

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\(^9^0\)

**Thunderstorm Winds**

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\(^9^1\)

Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\(^9^2\) However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

**Tornadoes**

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\(^9^3\) This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\(^9^4\) On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\(^9^5\)

**Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.**

---

\(^9^3\) Retrieved on 07.15.2021 from [https://www.earthnetworks.com/tornado/](https://www.earthnetworks.com/tornado/)

\(^9^5\) Retrieved on 07.15.2021 from [https://www.weather.gov/bgm/severedefinitions](https://www.weather.gov/bgm/severedefinitions)
**Santa Ana Winds.** A type of wind hazard that is peculiar to Southern California is called a *Santa Ana Wind*. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico). They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape. (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

---

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.  

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and

---

coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.100 101 102

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.103 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.104

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.105

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.106 Lightning that is produced

---

from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

Location of the Hazard

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the Cal Maritime campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

Extent of the Hazard

Severe weather hazards are non-spatial hazards that potentially affect all Cal Maritime campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to Cal Maritime reflect those of the surrounding community and County. As a result, all assets and people at Cal Maritime are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Vallejo area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as MODERATE. See each sub-hazard below for the planning committee’s sub-type extent ranking.

Wind Hazard: Non-Rotational

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.
**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{110}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 14-25: Fujita Tornado Scale (Pre-February 2007)\(^{111}\)

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as **LOW**.

### Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms.\textsuperscript{115} \textsuperscript{116} That said, according to the \textit{Glossary of Meteorology} published by the American Meteorological Society (AMS), a thunderstorm is reported as \textit{light, medium, or heavy} according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\textsuperscript{117}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- \textbf{Airmass Thunderstorm}: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{118}

- \textbf{Frontal Thunderstorm}: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{119} or

- \textbf{Squall-line Thunderstorm}: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\textsuperscript{120} \textsuperscript{121}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as \textbf{LOW}.

\textbf{History of the Hazard}

Severe weather hazards have been an annual occurrence in Solano County and on the Cal Maritime campus. Historical data for these hazards are presented below.

\textsuperscript{115} Retrieved on 07.15.2021 from \url{https://www.noaa.gov/explainers/severe-storms}
\textsuperscript{116} Retrieved on 07.15.2021 from \url{https://www.weather.gov/safety/thunderstorm}
Historical Storm Data Collection: NCEI Storm Events Database

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\textsuperscript{122} For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\textsuperscript{123} To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

\textit{Wind Hazards (excluding Tornadoes)}

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Solano County since 1996.\textsuperscript{124} Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\textsuperscript{125}

\begin{itemize}
  \item \textit{High Wind}: at least 42 events, or approximately 1.66 events per year\textsuperscript{126}
  \item \textit{Strong Wind}: at least 30 events, or 1.18 events per year\textsuperscript{127}
\end{itemize}

\textsuperscript{122} Retrieved on 07.19.2021 from https://www.ncdc.noaa.gov/stormevents/details.jsp

\textsuperscript{127} National Climatic Data Center. Storm Events Database. Retrieved 07.30.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+Strong+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SOLANO%3A95&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA
- **Thunderstorm Wind**: at least 6 events, or approximately 0.24 events per year.\(^{128}\)
- **All Wind Hazard events** (excluding Tornadoes): at least 72 events, or approximately 2.84 events per year.\(^{129}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Solano County, there have been at least 72 wind hazard events since 1996, excluding tornadoes.\(^{130}\) That translates to an approximate average historical frequency of occurrence of **2.84** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 78 events) and simultaneous Database searches of all severe weather hazard events (i.e., 72 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Solano County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{131}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 72 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

### Historical Wind Hazard Losses for Solano County since 1996

According to the NCEI Storm Events Database, the wind hazard events that Solano County has experienced since 1996 have been costly. There have been 3 deaths and 2 injuries, and property and crop damage estimates have totaled approximately $12,938,000 and $39,000, respectively.\(^{132}\)

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 3 reported events of tornadoes in Solano County, which translates to approximately **0.12** tornado events per year. All tornado reports in Solano County since 1996 have been of tornadoes with a severity rating of F0/EF0.

**Historical Tornado Hazard Losses for Solano County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Solano County has experienced since 1996 have been minimal. There have been no deaths, injuries, or crop damage reported, and property damage estimates have totaled approximately $26,000.

---

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been four (4) reported events of hail in Solano County, which translates to approximately **0.16** hail events per year. (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of five (5) reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Solano County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Solano County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Solano County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damage reported, property damage estimates have totaled approximately $29,000.
$100,000.\textsuperscript{137} (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Solano County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

\textit{Lightning}

Information from the NCEI Storm Events Database indicates that since 1996, there no reports of lightning hazard events in Solano County.\textsuperscript{138}

\textbf{Historical Lightning Hazard Losses for Solano County since 1996}

According to the NCEI Storm Events Database, there have been no reported lightning hazard events in Solano County since 1996.\textsuperscript{139} As a result, there are no deaths, injuries, or property or crop damages attributed to lightning in Solano County.

\textbf{All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database}

Information obtained from the NCEI Storm Events Database indicates that there have been 79 occurrences of the severe weather hazard in Solano County. This translates to 3.12 severe weather hazard occurrences per year.\textsuperscript{140}

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 86 events) and simultaneous Database searches of all severe weather hazard events (i.e., 79 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Solano County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{141}

such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 79 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical, Aggregated Severe Hazard Losses for Solano County since 1996

According to the NCEI Storm Events Database, the severe weather events that Solano County has experienced since 1996 have been costly. There have been 3 deaths and 2 injuries, and property and crop damage estimates have totaled approximately $13,064,000 and $39,000, respectively. However, it is important to note that for all Solano County severe weather hazard events recorded on the Storm Events Database, all deaths, injuries, and crop damage estimates, and approximately 99% of all property damage estimates, have been caused by wind hazard events alone.

Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April. From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Diablo Winds

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.  

---

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{149}

Figure 14-17: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\textsuperscript{150}

\textbf{Sundowner Winds}

Strong sundowner wind events occur approximately \textit{2-3 times per year}. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\textsuperscript{151}

\textbf{Historical Frequency of All Severe Weather Hazards}

Table below shows the average historical frequency of severe weather hazard events for Solano County since 1996.)

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within Cal Maritime campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the Cal Maritime campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.
Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

According to the 2012 Solano County Local Multi-Hazard Mitigation Plan, “severe weather,” which includes heavy rains coupled periodically accompanied by strong winds (including tornadoes), lightning, or hail, is considered to be a “high” threat to the general population and/or built environment of the County, as the potential for damage is widespread. As a result, severe weather with wind hazards (including tornadoes) is considered to have a high potential impact on the County and (by extension) on the Cal Maritime campus.

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

According to the 2012 Solano County Local Multi-Hazard Mitigation Plan, “severe weather,” which includes heavy rains coupled periodically accompanied by strong winds (including tornadoes), lightning, or **hail**, is considered to be a “high” threat to the general population and/or built environment of the County, as the potential for damage is widespread. As a result, severe weather with hail is considered to have a high potential impact on the County and (by extension) on the Cal Maritime campus.

**Lightning**

Lightning strikes the United States about 20-25 million times a year. Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured. Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance

---

claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.iii (Commercial claim payouts for lightning losses for the U.S. were not available.)

According to the 2012 Solano County Local Multi-Hazard Mitigation Plan, “severe weather,” which includes heavy rains coupled periodically accompanied by strong winds (including tornadoes), lightning, or hail, is considered to be a “high” threat to the general population and/or built environment of the County, as the potential for damage is widespread.iv As a result, severe weather with lightning is considered to have a high potential impact on the County and (by extension) on the Cal Maritime campus.v

Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The 2012 Solano County Local Multi-Hazard Mitigation Plan states that severe weather will continue to occur annually throughout Solano County, and that the frequency and probability of future occurrences of severe weather (including wind, tornado, hail and lightning) is “highly likely” and is expected to occur in the future.vi Also, according to the NCEI Storm Events Database, one of the severe weather hazards (i.e., wind hazards) have occurred in Solano County far more than once annually – an average of 2.84 times per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the Cal Maritime campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the Cal Maritime campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both 2012 Solano County Local Multi-Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the Cal Maritime campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for Cal Maritime is HIGHLY LIKELY. See Table below for probabilities of future occurrence for component severe weather hazards for the County and the Cal Maritime campus.
Table 14-30: Severe Weather Hazard Probabilities of Future Occurrence for Solano County and Cal Maritime

Vulnerability to the Hazard

People, structures, and assets on the Cal Maritime campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The Cal Maritime campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire Cal Maritime campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within the Cal Maritime campus are at risk from severe weather. There are approximately 78 buildings on the main campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due
to severe weather hazard are $83,596,545 for 47 of the buildings, and unknown for the remaining 31 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is not currently available, though CSU leadership may pursue such data in the future.

The population at the Cal Maritime campus varies throughout the day. As of Fall, 2019, Cal Maritime had 911 students and 329 faculty and staff. All are at risk from severe weather events, with 1,240 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to the Cal Maritime campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to Cal Maritime.

It is evident that the Cal Maritime campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
14.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU San Jose campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”

**NOTE: No interview was conducted with campus staff so no information can be included in this section.**

Resilience Variables Related to Campus Emergency Management
The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

1. Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as *Very High, High, Medium, Low*
2. Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as *Yes, No, In Progress, NA*

*NOTE: No interview was conducted with campus staff so no information can be included in this section.*

**Campus High Hazards and Potentially Vulnerable Populations**

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

**Table 14-31: CSU Maritime *Highly Likely, Likely and Possible* Hazards**

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\(^{156}\) Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\(^ {157}\) Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal

---

health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.\textsuperscript{158}

\textit{Erosion}

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

\textit{Landslides}

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied buildings which makes it a function of structural vulnerability and therefore, indirect. The degree of vulnerability to landslides by an individual considered at high risk, or even the general populations, also depends on human behavior, including many of the traditional social factors that are difficult to measure such as situational awareness, prior knowledge of hazards, and decision-making capabilities.\textsuperscript{159}

Landslides can result in primary lifeline failures through the loss of roads or power and communication lines. Transportation routes are often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods. Risk from landslide relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and

decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Tsunami**

TBD

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old. Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air

---

Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

15.1 University Profile

University History

CSU Monterey Bay’s history grew out of Fort Ord, a decommissioned Army base with a rich history going back to the early 20th century. In 1917, the U.S. Army established a military base in Monterey County, California -- Camp Gigling. Located on California’s central coast, the army installation served originally as a military training base for infantry troops. In 1940, the base was renamed Fort Ord, and seven (7) years later (in 1947) Fort Ord became a U.S. Army basic training center. Throughout the 1950s, 1960s and 1970s, Fort Ord was a major location for basic training, reaching its heyday during the Vietnam War. In all, more than 1.5 million men and women received basic training at Fort Ord. After 1975, Fort Ord’s mission changed, and light infantry troops occupied the base, operating without heavy tanks, armor, or artillery. In 1990, U.S. Secretary of Defense announced that the military would begin a process to reduce the number of nationwide military installations and Fort Ord was one of the bases named for closure. In September, 1994, Fort Ord was officially closed.

In anticipation of Fort Ord’s closure, local Monterey Bay community leaders proposed a plan that the soon-to-be decommissioned base be converted into a university. In June, 1994, that plan was approved, and the first classes at the aptly named California State University Monterey Bay (CSU Monterey Bay, Cal State Monterey Bay) began the following year, on August 28, 1995.

Since its inception, CSU Monterey Bay has grown from 654 students to well over 7,000 students. It is designated as a Hispanic-Serving Institution (HSI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The university divides its operations into administrative divisions, each under the direction of a vice president. The current CSU Monterey Bay leadership team of president and vice presidents includes; the University President, Provost and VP for Academic Affairs, the Executive Director University Corporation at Monterey Bay & VP for Administration & Finance, Vice President for Student Affairs & Enrollment Services, and the Vice President for University Advancement.
The CSU Monterey Bay Academic Senate and its Academic Senate Executive Committee, made up of elected representatives of the faculty, recommend academic policy to the president through a shared-governance process.

University Mission

“To prepare students to contribute responsibly to California and the global community by providing transformative learning experiences in an inclusive environment.”

The Strategic Planning Committee and working groups created a strategic plan, operating on five-year action cycles. The five-year action cycles focused on student success and on what the university’s respective region requires impact the lives and future of the community. Each cycle will stay true to the campus’ values. Additionally, it will update the goals and objectives to most effectively advance the mission of the university. Additionally, the strategic plan is the framework for processes and decision making. The plan informs and aids the University’s as priorities are determined. It guides the data to collect and evaluate in order to be effective in accomplishing University goals. It is the basis for making budget decisions and it serves as a reminder of what the University values most. The university prioritizes student success, inclusiveness, regional stewardship and global engagement, and finally, organizational learning.

University Location

CSU Monterey Bay is on the central coast of California, just two hours south of San Francisco. Located in Seaside, CA, CSU Monterey Bay’s campus is close to beaches, redwood forests, tidepools, and the Fort Ord National Monument. The campus is also close to the coastal communities of Pacific Grove, Monterey, and Carmel, and lies proximal to the Salinas Valley, an area known as the “Salad Bowl of the World” for its abundant agricultural production.

University Population

CSU Monterey Bay has a population exceeding 7,500 students. In the fall of 2020, the student population was overwhelmingly made up of undergraduate students. Latino students made up 45%, with White students making up 29% of the campus population.

15.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the
jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

**Requirement §201.6(c)(2)(i):** The risk assessment shall include a description of the type, location, and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

**Requirement §201.6(c)(2)(ii):** The risk assessment shall include a description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

**Requirement §201.6(c)(2)(ii):** The risk assessment must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

**Requirement §201.6(c)(2)(ii)(A):** The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

**Requirement §201.6(c)(2)(ii)(B):** The plan should describe vulnerability in terms of an estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate.

**Requirement §201.6(c)(2)(ii)(C):** The plan should describe vulnerability in terms of providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

**Requirement §201.6(c)(2)(iii):** For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

### 15.3 Hazard Identification and Risk Assessment

**Overview of California State University, Monterey Bay History of Hazards**

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI)
database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

**Hazard Identification**

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s *How-To Series*, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 15-1 (following).
<table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

Highly Likely- 76%-100% that the hazard would occur annually.
Likely- 50%-75% that the hazard would occur annually.
Possible- 11%-49% that the hazard would occur each annually.
Unlikely- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague).

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 15-2 below.)

**Descriptions of Identified Communicable Disease Hazards at CSU Monterey Bay**

CSU Monterey Bay has identified one (1) communicable disease hazard that has had the greatest impact on campus – COVID-19. The following is a brief description of the communicable disease hazard at CSU Monterey Bay.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It’s not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death. ⁵

Location of the Hazard

Communicable diseases have the potential to affect the entire CSU Monterey Bay planning area equally. As a result, the communicable disease hazard can be found at the CSU Monterey campus, which straddles the border of two (2) Monterey County communities – Marina, CA and Seaside, CA. Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) CSU Monterey are at risk of exposure to the communicable disease hazard.⁶

⁶ California State University. *About CSU.* Retrieved on 4.29.2021 from: https://www2.calstate.edu/csu-system/about-the-csu
CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For CSU Monterey Bay, approximately 46% of its 7,123 enrolled students (or 3,277 students) reside in student housing. 7,8

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 15-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

The Extent of CSU Monterey Bay Communicable Disease Hazards Except COVID-19:

Besides COVID-19, there was no information provided on other communicable disease hazards on campus.

The Extent of CSU Monterey Bay COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3. ¹⁰

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 55 cases of COVID-19 at CSU Monterey Bay. Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19

---

case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 15-5 and 15-6 show campus-level and County-level COVID-19 Case data for CSU Monterey Bay. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics have (and will continue to have) direct impact on life, health, and safety across the CSU system (including the CSU Monterey Bay campus). The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU Monterey Bay students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19

pandemic and could occur again with more virulent strains of communicable
diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU
Monterey Bay) vary both by level of containment (BSL) (described previously) and by
level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the
procedures and required levels of containment in a laboratory setting, Risk Groups
(RGs) reflect the potential effects of disease exposure on humans or animals. Like
BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing
minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very
serious or extreme risks to individuals and public. BSLs generally correlate with Risk
Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are
exceptions (e.g., production volumes, high-risk procedures, etc.). 13

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH
Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 5-6: WHO Risk Group Categorization14

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not</td>
</tr>
</tbody>
</table>

usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)

Table 15-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall into these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

</tr>
</tbody>
</table>
decontamination procedures to eliminate the possibility of an accidental release.

Probability of Future Occurrence of the Hazard

There have been cases of a variety of communicable disease throughout the CSU system, including COVID-19 (SARS-CoV-2), Meningitis, Measles, Influenza (Including H1N1/Swine Flu), Tuberculosis, Norovirus, Mumps, E. Coli, and Sexually Transmitted Diseases (STDs). However, there are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.

Table 15-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 15-8: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence. Note: Each communicable disease’s
probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the CSU Monterey Bay campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given
day. (As of Fall 2019, the CSU System had 480,541 students and 53,763 faculty and staff.)\textsuperscript{16,17} Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic on the CSU Monterey Bay campus.

Estimate of Potential Losses

**COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities**

The most prescient metric for estimating losses from COVID-19 is loss of life.\textsuperscript{16} The nationwide campus-related COVID-19 death rate of 0.02\% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU Monterey Bay) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities.\textsuperscript{18} The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring

\textsuperscript{16} The California State University. *Enrollment*. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

\textsuperscript{17} The California State University. *Employee Head Count by Campus*. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx

Semester, 2020. Several CSU campuses saw refund losses surpass $10 million. (See Table CD.8.)
Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 15-11.) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems. Table 15-12 shows the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus...
shutdowns, educational disruption, and economic harm to the CSU system, including CSU Monterey Bay. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.
Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

- Data that could be collected prior to the next update in order to improve this methodology includes:
  - Data regarding infection rates at the campus level and for specific populations;
  - Data regarding communicable disease case numbers and outcomes, by CSU campus;
  - Data regarding projected population changes;
  - Data regarding absenteeism; and
  - Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

---

**Dam and Levee Failure**

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water.25 Most levees in California are intended to withstand peak water levels generated by heavy

---

precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from over toppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

Monterey County is home to a variety of flood control facilities and levee systems throughout the county. Seaside and the CSU Monterey Bay campus sit between the Salinas River and the Pacific coastline. The primary dam within Monterey County posing a threat is the San Antonio Dam on the border with San Luis Obispo County. There are levee facilities in Monterey County to the north, east, and south of the campus including levees that separate the Salinas River influences from the community.
Levees have been constructed to protect portions of Monterey County along the Salinas River. A series of levees have been constructed to protect lands alongside the Elkhorn Slough providing protection from tidal and coastal influences. Additionally, levees line parts of the Pajaro River on the Santa Cruz County line. **The CSU Monterey Bay campus is not located in a levee protected area.**

The county is additionally downstream of facilities located in other counties. The primary dam facility that could present a threat to the CSU Monterey Bay campus community is in neighboring San Luis Obispo County containing significant amounts of water. The Nacimiento Dam regulates the Nacimiento River 110 miles upstream that feeds into the Salinas River and eventually into the Pacific Ocean. The Salinas River is almost 4 miles east of the campus. **The campus sits on a bluff that is elevated from the river valley.** A failure of this facility is expected to produce inundations that cover sizable areas through the Salinas River Valley including the area separating the campus from the City of Salinas. Transportation routes accessing locations to the north and east lie within the inundation zones for both the San Antonio and Nacimiento Dams.
Figure 15-4: San Antonio Dam Breach Inundation Map

26 California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.

- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.

- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

The CSU Monterey Bay campus lies outside of the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the CSU Monterey Bay campus is expected to remain out of the inundation area. The inundation area is expected to spread water to the north downstream along the Salinas River. However, there are multiple transportation corridors that lie within the dam inundation zones that could compromise transportation routes and areas the campus community reside or work. Based on these factors, the planning committee ranks the extent of the hazard as **Low**.

Extent: Levee Failure

Levees are used along numerous flood control channels and other waterways including the Salinas River, Pajaro River, and the Elkhorn Slough. The CSU Monterey Bay campus remains outside of any levee flood protected area. In the event any of

these channels were flowing at elevated levels and a failure of a levee were to occur, the community surrounding the campus would likely experience flood related damages. This specific hazard could alter the ability of the campus to maintain operations as damages would be extensive. State Route 1 and US Highway 101 cross through the levee protected zones in addition to the dam inundation zone creating a potential for community-wide isolation from access, evacuation, resources, and other services from outside of the Monterey Bay area. Based on these factors, the planning committee ranks the extent of the hazard as Low.

History of the Hazard

There are no records of dam or levee failures in areas that present a threat to the CSU Monterey Bay campus. Monterey County has not identified a history of dam or levee failures elsewhere in the County. The County has identified that the San Antonio Dam has spilled over in 1958, 1969, 1983 and the Nacimiento Dam has spilled over in 1982 and 1983. None of these dam spill over events caused any damages, injuries, or fatalities.

Potential Impacts of the Hazard

Dam Failure Impacts - While the campus is not within a dam inundation zone, transportation routes, critical infrastructure, and campus community members may reside within inundation zones. Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues
Probability of Future Occurrence of the Hazard

Monterey County is determined to be at risk from 4 dams around the county. The San Antonio Dam and the Nacimiento Dam are 85 and 95 miles respectively upriver on the Salinas River. However, the dam inundation zone for both dams follows the Salinas River not in proximity to the campus. The campus is 3 miles from the boundary of the dam inundation zone. There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on no historical occurrences, the likelihood of this hazard is low.

The probability of future occurrence for and the regulated monitoring, maintenance and inspections in place, both dam and levee failure probability is Unlikely.

Vulnerability to the Hazard

Given high priority monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. In addition, the campus does not lie within an inundation zone. As such, the campus is not considered to be truly vulnerable on a daily basis. However, in the unlikely event of a catastrophic failure, the effects of flooding from compromised dams and levees on campus would most likely be limited to indirect or secondary effects in terms of disruption to regional transportation networks and services, and the amount of time to respond to the needs of the campus community prior to inundation will be limited. Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations in the event of a low probability, catastrophic event.

The distributed placement of levees, many near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in the vulnerability of numerous displaced individuals and households. The lack of flood insurance will cause extreme additional financial burdens on those affected.

Vulnerability to a dam or levee failure near the CSU Monterey Bay campus will vary depending on the degree of breach or structural failure and when the failure were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in the case of extremely rare region-wide events, this
vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Some areas of particular vulnerability to dam failure from the Matthews Dam on the campus includes:

- Limited vulnerabilities of the main campus.
- US Highway 101 vulnerable to the effects of dam inundation flows through the length of the Salinas Valley.
- State Route 1 vulnerable to the effects of dam inundation limits the access to and from the campus servicing northern routes into Santa Cruz County.
- Substantial agricultural production lies within the dam inundation directly impacting those campus community members relying on agricultural as an income source.
- The campus is vulnerable to the economic effects resulting from the destruction of agriculture and industry within the inundation zone.
- Campus community members residing in areas east and north of the Salinas River such may become isolated from campus.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $401,286,223. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU Monterey Bay.

Vulnerability Assessment Conclusions
While the occurrence of dam and levee failures have not been historically relevant near the CSU Monterey Bay campus, the potential for hazards related to the region’s levees and dams still exists. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences would generate catastrophic results to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.
Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.

**Drought**

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir
levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.

- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - Monterey Bay) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified by the campus planning committee for Monterey, CA where CSU – Monterey Bay is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.28

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout the region surrounding the planning area and across the state, and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies.

In addition, although drought affects the entire CSU system wide planning area, the extent of the hazard is variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities historically impacted by drought within each jurisdiction. Based on input from the campus planning

committee, water rights and local seaside groundwater aquifer levels are considered to be serious issues even though no campus level impacts have been recorded.

In addition, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels in California have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines, and these risks are applicable concerns for the campus over the long term.

For CSU – Monterey Bay, based on qualitative input from the planning committee, the extent of the hazard is Moderate (corresponding to D1-D2 on the extent scale below). However, the campus planning committee recognizes that the potential for more severe conditions exists and is tied to regional water resource vulnerabilities.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

**History of the Hazard**

Historically, drought has been so prevalent in California that its presence is almost continuous, including the region, county and city surrounding the CSU - Monterey Bay footprint. Although no drought events have been recorded specific to the campus, the planning committee indicates that occurrences are frequent in the surrounding area. According to the US Drought Monitor, Time Series data, Monterey County has experienced 6 or more periods of drought from 2000-2021, including the severe statewide drought from 2012-2019.

Figure 15-5: Periods of Drought in Monterey County, California, 2000 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and

---

resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.\textsuperscript{31}

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. \textsuperscript{32}

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2- to 3-month period in 2000 and 2011), some degree of drought conditions has been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 15-6: Periods of Drought in State of California, 2001 – 2021\textsuperscript{33}

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the CSU - Monterey Bay campus planning area:

\textbf{2012 – 2017} – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments

\begin{itemize}
  \item \textsuperscript{31} NCEI. Storm Events. Retrieved on 5.4.2021 from: https://www.ncdc.noaa.gov/stormevents
\end{itemize}
were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”’. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent. 34

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the CSU - Monterey Bay campus planning area is a reduction in water availability for the municipal area tied to the campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - Monterey Bay to some extent includes these vulnerable resources based on the campus landscape (trees and other flora).

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. 35 However, the wildfire hazard is analyzed separately in this plan. (See wildfire hazard).

In reviewing the occurrences of drought for Monterey County (which surrounds CSU - Monterey Bay), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012 - 2017) state-wide drought

disaster. Though data sources do not provide data for tree mortality specific to CSU - Monterey Bay, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus; however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area. 36

At present, drought related damage to campus buildings and infrastructure at CSU - Monterey Bay has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - Monterey Bay is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s

Regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Monterey Bay. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Probability of Future Occurrence of the Hazard

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that CSU - Monterey Bay lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Monterey Bay campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - Monterey Bay planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs.

---

Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.  

Vulnerability of Populations

Drought vulnerabilities include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the CSU – Monterey Bay campus.

Property Vulnerability

Drought vulnerabilities include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the CSU - Monterey Bay campus.

Natural Environment Vulnerability

Natural environment vulnerabilities are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds. The core issue shaping the impact of drought throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to the overall threat and asset findings shaping the potential severity of drought for the CSU – Monterey Bay campus, primary concern is focused on seaside groundwater levels, which are currently unknown. As such, efforts have been made to partner with the Monterey Pipeline Project in order to reduce the vulnerability of the campus population and other water dependent assets. At the state level, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition,
groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.40

Critical Facilities Vulnerabilities

Drought vulnerabilities for CSU - Monterey Bay’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

Estimate of Potential Losses

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of Monterey and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

Vulnerability Assessment Conclusions

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

Identified Data Limitations

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.

**Earthquake**

**Description of the Hazard**

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.
**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU Monterey Bay is located in the Monterey Bay area south of the San Francisco Bay region. In general, numerous fault systems surround and traverse throughout the Monterey Bay Area and Monterey County including the area of CSU Monterey Bay. In many places, the populated areas of the Monterey Bay region and surrounding cities, the ground is saturated with sediment eroded from the hills by means of multiple stream channels. Liquefaction zones rated at moderate susceptibility exist in areas along the Salinas River and the contributing creeks.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 20 miles northeast of the CSU Monterey Bay campus. In addition to the San Andreas Fault, Monterey County is home to or near additional fault systems with the potential to generate strong ground shaking. Two miles north of the campus traversing the City of Marina, the Reliz Fault extends from the southeast to the northwest. The 55-mile-long Monterey Bay-Tularitos Fault extends southeast to northwest from Carmel Valley through Monterey and into the Pacific Ocean is 5 miles southwest of the CSU Monterey Bay campus. The San Gregorio Fault parallels the coastline off of Big Sur 14 miles southeast of the campus. The entire Monterey Bay Area is saturated with numerous additional faults mostly paralleling the San Andreas Fault to the northwest. These fault systems are located on each side of the campus.
The entire CSU Monterey Bay campus resides in areas designated to be areas of low liquefaction susceptibility. The liquefaction zones additionally appear in areas where critical transportation routes extend to other areas including State Route 1 to the San Francisco Bay Area and US Highway 101 to points north and south. Liquefaction zones additionally appear scattered throughout the county and neighboring communities.

The CSU Monterey Bay at Ryan Ranch in Monterey, CA is also located in an area designated as facing a low liquefaction susceptibility. However, an area of high liquefaction susceptibility follows the path of State Route 68 and State Route 218 providing the primary methods of accessing the Monterey facility and transportation between Monterey and Salinas.
Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity, and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude

---

41 County of Monterey, Monterey County GIS/Maps, Geologic Hazards Map, https://www.co.monterey.ca.us/government/departments-i-z/resource-management-agency/gis
of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude
represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 15-9: Earthquake Magnitude and Equivalent Energy Release

Numerous fault systems surround and traverse throughout the Monterey Bay Area and Monterey County including the area of CSU Monterey Bay. The campus is not in a liquefaction zone but such zones are located in the Monterey Bay area. In addition, several severe and even catastrophic events have taken place. Based on these factors, the planning committee ranks the extent of the hazard as Moderate.

History of the Hazard

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Likewise, Monterey County also has a long history of earthquake activity. The entire area of Monterey Bay area is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The above earthquakes had federal disaster declarations declared:

- Loma Prieta (DR-845-CA)
- San Simeon (DR-1505-CA)
- American Canyon (Dr-4193-CA)

The April 18, 1906 San Francisco Earthquake became one of the most well-known earthquakes in California history. The earthquake caused extensive damage to buildings, bridges, water systems, and critical facilities. Damage was experienced well beyond San Francisco including areas such as Monterey and Santa Cruz. 3,000 people were killed and thousands more injured. The San Francisco Earthquake was found to shift the course of northern California rivers. The shaking was felt from Oregon to Los Angeles.

The October 17, 1989 Loma Prieta Earthquake shook a large part of northern California, especially the San Francisco Bay Area. The earthquake caused $5.9 billion in damages, most extensively in San Francisco, the East Bay, and South Bay areas. The earthquake resulted in extensive infrastructure damages, 12,000 displaced, 3,757

---

44 Monterey County Multi-Jurisdictional Hazard Mitigation Plan, June 2015
injuries, and 63 fatalities. The earthquake was provided a federal disaster declaration (DR-845).

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Los Angeles area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Monterey could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Monterey could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Monterey County region limiting immediate assistance that the campus may normally expect.

Local impacts to CSU Monterey Bay campus caused by an earthquake could include:

- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway and roadway system
- Structural damage to bridges over waterways and flood control channels such as the Salinas River
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to levees along Salinas River, Elkhorn Slough, and Pajaro River
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Monterey County fault systems surrounding the Monterey Bay is included in the following table.

45 Monterey County Multi-Jurisdictional Hazard Mitigation Plan, June 2015
The Monterey County Multi-Jurisdictional Hazard Mitigation Plan identifies that the region experiences small earthquakes every year. The Plan further estimates the probability for the San Andreas Fault to produce a Magnitude 6.7 or greater earthquake in the next 30 years is 21%.

Based on the earthquake shaking potential in the Monterey Bay area, the proximity to the above listed fault systems, and low liquefaction potential existing throughout the campus, the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of CSU Monterey Bay places the campus in a suburban community near residential, commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to the Monterey Bay region generally surround the area and some cross near the CSU Monterey Bay campus. The campus resides in a region that is exposed to fault systems on all sides. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the CSU Monterey Bay campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the area. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in
The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with sheltering and care of those unable or unwilling to return to their homes. Damages to the homes of the members of the campus community may place greater demands on campus resources and capabilities in the short-term period following a seismic event.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. This may be heightened in the southwestern portions of the campus as this area has been identified as being within a liquefaction zone. As the CSU Monterey Bay campus is downstream from dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

The Monterey Bay region is served by only two primary surface transportation routes to get in and out of the region. The primary route being US Highway 101 providing roadway access to the San Francisco Bay Area 60 miles to the north and to the Los Angeles area 300 miles to the south. California State Highway 1 provides access to the Santa Cruz area and also extends to the south however this is a winding route along seaside cliffs subject to landslides. A major earthquake has the potential for rendering these critical lifelines and supply routes inoperable and forcing the campus community to be self-reliant for a period of time.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses
Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $401,286,223.

The facility identified as being located in a Moderate PGA Zone is the CSU Monterey Bay at Ryan Ranch Monterey, CA.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater Monterey Bay region and the CSU Monterey Bay campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU Monterey Bay campus and community.
In the event that a major earthquake was to strike along the many fault systems surrounding Monterey, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Monterey Bay region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Erosion

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.”\(^{48}\) Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as

storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the CSU Monterey Bay campus with erosion-prone characteristics.

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While coastal erosion can happen in any storm, it is more likely during El Nino events, which occur every 5-7 years. The CSU Monterey Bay campus is located less than a mile from the Pacific Ocean coastline, where the largest concentration of coastal dunes in California is located. This coastline is experiencing continual dune erosion.\(^{49}\)

\(^{49}\) NOAA. Retrieved 2/7/21 from https://montereybay.noaa.gov/resourcepro/resmanissues/coastal.html
Extent of the Hazard

Erosion is occurring on the Pacific coastline west of CSU Monterey Bay. The average dune erosion rate between Moss Landing and Pacific Grove is approximately 2.6 feet per year. At Fort Ord Dunes State Park, adjacent to campus, the coastal retreat rate is believed to be about 7 feet per year, one of the highest rates of shoreline erosion in California. 50 51

Though no history of occurrence has taken place on campus, the severity of erosion closely adjacent to the campus along with the potential for erosion on campus in

51 Monterey County. Retrieved 2/7/21 from https://www.co.monterey.ca.us/home/showdocument?id=13709
areas with relevant characteristics, the planning committee ranks the extent of the hazard on campus as **Moderate**.
History of the Hazard

Following an El Nino event in 1997, a survey revealed that the City of Marina dunes, to which the campus is adjacent, retreated 50 feet. While coastline erosion is ongoing, no incidents of erosion have been reported on the CSU Monterey Bay campus.

Potential Impacts of the Hazard

Coastal erosion can result in severe impacts to infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. As a result, and in consideration of the potential extent of erosion both adjacent to, and on the campus, the probability of at least a limited degree of erosion occurring somewhere on the campus in the future is **high** over the long term.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Monterey Bay infrastructure and buildings located on steep slopes, in areas with little vegetation, in areas with conducive soil types, or in coastal erosion hazard zones are more vulnerable to erosion. Most of the campus facilities are located upland and on well-drained soils, making it relatively safe from destructive coastal erosion.

In the wider Monterey Bay community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.
Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

Vulnerability Assessment Conclusions

While the ability to predict future erosion on the CSU Monterey Bay campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Heat**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.\(^{52}\)

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.\(^{53}\) As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.\(^{54}\)

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.\(^{55}\) In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.\(^{56}\)

**Location of the Hazard**

Extreme heat events are a non-spatial hazard, and may occur throughout the CSU Monterey Bay campus.

---

\(^{54}\) Ibid.

Extent of the Hazard

Extreme heat has a wide range of extent and severity markers and characteristics. In the City of Seaside, where the campus is located, monthly average maximum temperatures in June through October range approximately from the low 60s to the high 60s. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at the Monterey Weather Forecast Office was 104°F on October 8, 1996. Given limited extreme heat events and the unique cooler conditions along the Monterey coast where the campus is located, the planning committee ranks the extent of the hazard as Low.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105°F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach those criteria.57 In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 15-11 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

Figure 15-11: Methodology for Determining Heat Index

---

As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.

</tbody>
</table>

History of the Hazard

Data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database show three excessive heat events that have impacted Monterey County since 1987, but no excessive heat events that have affected the coastal areas of the county near the CSU Monterey campus specifically.

**July 21-22, 2006:** These heat events were part of a record-breaking heat wave that affected much of the state between July 16 and July 26, 2006. An all-time record for statewide energy consumption was reached on July 24, 2006 with more than 50,000 megawatts of usage.59

**October 2, 2012:** This event was part of a statewide heat wave that caused temperatures approximately 15 to 20 degrees above normal in many areas. One death was attributable to this heat event.

Potential Impacts of the Hazard

---

CSU Monterey Bay may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

Only one heat event has impacted Monterey County in the last 10 years. Using the scale provided, it is Unlikely that the hazard will occur annually. It is also important to consider that the Multi-Jurisdictional Hazard Mitigation Plan prepared by Monterey County does not profile excessive heat as a hazard because, “While extreme temperatures are known to occur, prolonged heat waves are rare” in the area.\(^{60}\)

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.\(^{61}\) This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Extreme heat is not a hazard that CSU Monterey Bay should face on a regular basis. However, the campus is aware of the effects of climate change and how rising temperatures may affect their students, faculty, and staff in the future. Though the

---

\(^{60}\) Monterey County Multi-Jurisdictional Hazard Mitigation Plan. Identification and Screening of Hazards. Print. Retrieved 01.28.21 from: https://www.co.monterey.ca.us/home/showdocument?id=13709

campus does not face high risks of extreme heat at this time, they are looking to prepare for future impacts.

**Estimate of Potential Losses**

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.
Vulnerability Assessment Conclusions

While the ability to predict future heat events at the CSU Monterey Bay campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), North-Central California has warmed about 1.5 – 2 degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.62

Cold

Description of the Hazard

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.63

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.64 This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underly tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes.65 It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases.66 The risk of frostbite is

66 Ibid.
increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions. Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6°F. Hypothermia occurs when your body temperature falls below 95°F. As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

Location of the Hazard

Extreme cold events are a non-spatial hazard and may occur at the CSU Monterey Bay campus.

Extent of the Hazard

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in Monterey Bay are typically in the mid-40s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in Monterey Bay was 20°F on December 22, 1990. Based on no extreme cold events and just 9 frost/freeze events since 1996, the planning committee ranks the extent of the hazard as Low.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30°F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure 15-10 (following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow). Given the historical and potential occurrence of freezing temperatures, but a low probability of

---

extreme cold, the planning committee ranks the extent of the hazard as Low to Moderate
In 2011, the National Weather Service introduced an experimental program that issued warnings for extreme cold events, independent of other severe weather warnings. The test areas included North and South Dakota and Minnesota. However, in 2012, after a single season of use, the program was abandoned, based on reports of confusion among test audiences.69

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, Monterey County has had nine frost/freeze events dating back to 1990, but no extreme cold hazards. [Records for this hazard were first recorded in 1996].

Potential Impacts of the Hazard

Should an extreme cold event occur, CSU Monterey Bay might experience impacts due to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

Probability of Future Occurrence of the Hazard

The Monterey Bay area has experienced freeze/frost events, but has never experienced an extreme cold event. Due to the campus's location in a temperate climate, it is **Unlikely** that this hazard will occur annually.

Vulnerability to the Hazard

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more likely to suffer illness or death as a result. This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Estimate of Potential Losses

Based on the previous historical occurrences of extreme cold events, annualized losses are considered to be negligible. In an extreme cold event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future extreme cold events at the CSU Monterey Bay campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), areas in North-Central

---

California have warmed approximately 1.5 – 2 degrees on average over the last century, with less rainfall. This may lead to fewer frost/freeze events in the future.\textsuperscript{71}

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

\textit{Flood}

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing

flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Floods can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect
the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

Atmospheric Rivers

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California, they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Location of the Hazard

Seaside is located in Monterey County on the Pacific coast between Monterey and Santa Cruz. Monterey County can experience flooding from overflowing rivers, streams, and heavy precipitation events in low lying areas. These areas often experience shallow flooding impacting roadways and other areas where drainage is inadequate. The western side of the campus leads to State Route 1, the primary north-south connector and the Pacific Ocean. The Salinas River flows 4-5 miles to the east of the campus after traveling through the length of the Salinas Valley. The communities in and west of the Monterey Bay area are in some cases densely populated while other communities are developed with less density. The Salinas Valley is notable for rich agricultural production.

---

72 National Oceanic and Atmospheric Administration, “What are atmospheric rivers?”, https://www.noaa.gov/stories/what-are-atmospheric-rivers

The CSU Monterey Bay campus is located elevated on a bluff that overlooks the Salinas River limiting the flooding potential that exists in the low-lying areas. The campus is situated on a topography of rolling hills 200-300 feet higher than the coast and river channel. Creek beds that have been carved into valleys among the hills surround the campus. The majority of the CSU Monterey Bay campus sits within a Special Flood Hazard Area (SFHA) Zone X: Area of Minimal Flood Risk designation on the Flood Insurance Rate Map. The southwest corner of the campus containing Freeman Stadium and the athletic fields, and the aquatic center resides in a Zone X: 0.2% Annual Chance Flood Hazard.
Extent of the Hazard

The CSU Monterey Bay campus is located in a designated Zone X: Area of Minimal Flood Hazard with the exception of the area containing the athletic fields and stadium south of Divarty Street and west of General Jim Moore Blvd. The portion of the campus containing the athletic facilities are designated Zone X: 0.2% Annual Chance Flood Hazard. The access routes into and out of the campus servicing locations to the
north and east are found in areas primarily designated as Zone X: Area of Minimal Flood Hazard, access routes to and from the south via US Highway 101 are located in Zone X: 0.2% Annual Chance Flood Hazard. Based on no history of flood events on campus, and its location in an area of minimal flooding, the planning committee ranks the extent of the hazard as **Low**.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

**Table 15-21: Flood Zone Designations and Descriptions**

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>

</tbody>
</table>
Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.

Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.

Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.

Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.

Flooding in the Monterey Bay communities and the broader Monterey and Santa Cruz Counties region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the CSU Monterey Bay campus. No history of flood on campus is reported, and occasional heavy rainfall events will sometimes produce small, isolated pockets of ponding in low lying areas.

73 Monterey County Multi-Jurisdictional Hazard Mitigation Plan, June 2015
### Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Potential isolation from other regions and access to support, resources, or evacuation
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

**Probability of Future Occurrence of the Hazard**

Monterey County is determined have considerable portions of the county to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common in the Monterey Bay area with winter storms that are saturated with subtropical moisture.

The area surrounding the CSU Monterey Bay campus does not generally promote conditions for flood waters to accumulate. The majority of the campus is designated as Zone X (Area of Minimal Flood Hazard). However, the area containing the sports complex is designated as Zone X (0.2% of Annual Chance of Flood Hazard). There are specific buildings and areas of the campus that have a greater risk for isolated flooding. The area is also subject to isolated urban or street flood events providing a demonstration of potential flood activity.

The probability of future occurrence for flooding is **Unlikely**.

**Vulnerability to the Hazard**

The CSU Monterey Bay campus is subject to the effects of limited and isolated flooding and ponding resulting primarily from excessive precipitation and isolated strong storms. The vulnerability to flood among the people and infrastructure is reduced as the campus is located in an area designated as having a minimal flood risk. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas in low lying areas of the campus or Seaside due to overflow or damage to drainage or flood control systems. The flood
control channels and drainage systems that surround the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the CSU Monterey Bay campus will vary depending on when the flood was to occur and on the location of people or assets in any low-lying areas on campus. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community in any low lying areas may become trapped on campus depending on the level of flooding occurring on surface streets. However, in rare, region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

CSU Monterey Bay is in a location separated from the larger surrounding communities by areas that have the potential for flooding. When these areas are inundated with flood water, the potential for access barriers, contaminant release into flood waters, and creating physical isolation presenting vulnerabilities to individuals from the campus community regarding challenges to health and safety. The area surrounding the campus is filled with agricultural land uses; flooding of these areas may result in agricultural contaminants to be released into flood waters.

During low probability, severe flood events, some campus buildings and infrastructure in low lying areas might be vulnerable to large-scale flooding that reaches the university. Campus utilities and communication capabilities might be impacted by flood waters rendering them disabled. A rare flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls in any low lying areas may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. In such areas, flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.
Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $401,286,223. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions
While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods.

The potential for flooding generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for rare, widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls located in low lying areas.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Hazardous Materials**

**Description of the Hazard**

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”

Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks,

---

accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards:** fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards:** carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail

---

• May produce cascading disasters
• Response may be hindered by a disaster’s impact on the physical environment

Location of the Hazard

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. Please refer to Annex 7 for the map identifying the types and locations of hazardous materials and infrastructure on or near the CSU – Monterey Bay campus. The planning committee indicates that diesel generators and propane tanks are located on campus along with possible unexploded military ordinance. A gas pipeline runs through campus and one hazardous waste site is nearby. Also, the campus maintains a “90-day” facility for storing hazardous materials. At larger scales (beyond the campus planning area) a moderate degree of hazardous materials and infrastructure are located throughout the city and county of Monterey.

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

However, for the CSU – Monterey Bay planning committee, no hazmat events have taken place on campus. In addition, one gas pipeline and 1 hazardous waste site are located very close to the campus. Based on these factors, it is prudent to rank the extent of the hazard for the CSU – Monterey Bay campus as Low, but also to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. 79 That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the

rush to address and recover from immediate disaster threats, and that responsible
parties may have an incentive to understate the extent of releases or not to report
them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials
Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th,
2021 already 2096 spill events had occurred. Such events have occurred in all the
cities and/or counties where CSU campuses are located.\(^{80}\)

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-
technological hazard events (Natechs), 400 hazardous materials events are tied to 32
past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake
alone.

For more details on specific hazmat events, please refer to the local, county and/or
multi-jurisdictional hazard mitigation plans where CSU campuses are located at:
https://www.caloes.ca.gov/cal-oes-divisions/hazard-mitigation/hazard-mitigation-
planning/local-hazard-mitigation-program

According to the campus planning committee, no hazmat events have taken place on
the CSU – Monterey Bay campus.

Potential Impact of the Hazard

A large hazardous materials release could affect an entire community or city under
certain conditions related to direction of air flow (air-based chemical release) and
population density or the contamination of a community’s main water supply. Either
type of release could necessitate large scale evacuation. By contrast, in the rural
unincorporated areas where population densities are low, even in the event of a large
release, the number of homes that may need to be evacuated would be significantly
lower than in an urban environment. The occurrence of a hazmat incident can also
result in the shut-down of transportation corridors which can last for hours at a time
while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness
if absorbed through the skin, injected, ingested, or inhaled. Contaminated water
resources become unsafe and unusable, depending on the amount of contaminant.
Some chemicals cause painful and damaging burns if they come in direct contact with
skin. Prolonged and concentrated exposure to such chemicals can produce severe
long-term impacts to respiratory, endocrine and nervous systems, heart and brain
health.

\(^{80}\) Cal OES. Spill Report View. Retrieved 04.21.2021 from:
https://w3.calema.ca.gov/operational/malhaz.nsf/$defaultView?OpenView&Start=121&ExpandView
The potential impacts of chemicals and toxic gases discussed here to some degree apply to the students, staff and environment on the CSU – Monterey Bay campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Monterey Bay) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming

---

into contact with toxic substances due to the presence of synthetic and hazardous materials.

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the CSU – Monterey Bay campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low- the campus has not experienced a hazmat event. In addition, nearby hazardous materials and infrastructure may increase probability of a campus-related event. However, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a large risk to the CSU – Monterey Bay campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: diesel generators (fuel) and propane tanks pose a risk to the campus. In addition, a gas pipeline and a hazardous waste site are extremely close to the campus footprint. Gases and chemicals or hazardous waste, if spilled or released, could severely impact human health and campus operations. Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Monterey Bay leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack
prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

**Vulnerability Assessment Conclusions**

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Monterey Bay) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Monterey County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Monterey Bay campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

**Identified Data Limitations**

The CSU – Monterey Bay planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

---

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 15-17. Based on the Figure below, the Monterey Bay campus is located within an area of moderate landslide susceptibility.
Extent of the Hazard

Monterey County is susceptible to slope instability in the Santa Lucia Mountain Range and fault zones. Landslides are more likely to occur in the steep slopes south of Monterey Bay and along the coastline. However, the indirect impacts of landslides in the region may cover a larger geographical extent. Based on the location of the campus inside a moderate the landslide risk area, and an extensive history of occurrences in the vicinity, the planning committee ranks the extent of the hazard as Moderate.

History of the Hazard

NOAA recorded 20 debris flow events in Monterey County from 2012 to 2019. Several of these happened inland from Monterey Bay campus, in Spreckels, Prunedale, and Carmel Valley. FEMA has declared 8 major disasters involving landslides, mudslides, or mud flows since 1978. Recently, landslides have occurred on Highway 1 between Carmel and Big Sur and have resulted in road closures. No history of occurrences are reported on the campus, though nearby transportation routes have been affected.

Potential Impacts of the Hazard

CSU Monterey Bay may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in Monterey County and therefore are highly likely to occur in the future. However, given the topography of the campus, the probability of a landslide directly impacting the campus is reduced. The planning committee ranks the probability of the landslide hazard directly impacting the campus as Unlikely. The probability of experiencing secondary effects of a landslide such as loss of power or transportation disruption is Possible on an annual basis.

Vulnerability to the Hazard

There are no known hazards directly on the CSU Monterey Bay campus or its immediate vicinity, making it relatively safe from direct landslide impacts. While landslides in Monterey County may impact University operations, there is low vulnerability to the hazard.

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and
utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress.

Any population proximal to a landslide when it occurs is vulnerable to its impacts. The vulnerabilities identified (above) exist to some degree on the campus. Campus leadership may decide to conduct a broader assessment in the future.

Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Monterey Bay.

Vulnerability Assessment Conclusions

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the CSU Monterey Bay campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.

**Power Outage**

Description of the Hazard

Monterey Bay, California is a bay along the Pacific Ocean along the California shores south of San Francisco and San Jose. The Bay spans from Santa Cruz in the north to Monterey Peninsula in the south. Monterey Bay is made up of multiple cities including Santa Cruz, Capitola, Aptos, Rio Del Mar, La Selva Beach, Moss Landing, Marina, Seaside, Sand City, Monterey, New Monterey, Pacific Grove, Carmel, and Carmel Highlands.

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An
interruption in the supply or distribution of these commodities can leave highly populated areas like Monterey Bay without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the CSU Monterey Bay campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of CSU Monterey Bay student residents in on-campus housing would also be affected by a power outage on campus and in the area.

Additionally, a severe outage to the cities making up Monterey Bay would also directly affect the campus and the community.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions are:

- **Planned**: Some disruptions are intentional and can be scheduled based maintenance or upgrading needs.
- **Unscheduled**: Some intentional disruptions must be done "on the spot" in response to an emergency.
- **Demand-Side Management**: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- **Load Shedding**: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, as a hazard, it has the potential to occur and affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard

CSU Monterey Bay has experienced power outages will experience them in the future. In the past, power outages have affected the campus by equipment malfunctions and experienced damage due to the infrastructure from storms and vehicular accidents. Power outages impacting the campus have been blackouts that lasted minutes to those spanning anywhere from several hours to days.

Potential Impacts of the Hazard
Instructors, campus residents, staff and administrators rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

**Climate Change and Energy Shortage**

Climate change is expected to bring more frequent and intense natural disasters. Over the years, what was once a disaster uncharacteristic to landscape is now occurring outside of historical areas. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. Monterey Bay communities experience such outages. As such, the probability ranking for the Monterey Bay area is **Likely**.
the CSU Monterey Bay campus has also recorded power outage events, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

**Estimate of Potential Losses**

The data provided by CSU Monterey Bay State does not report any value for potential losses due to power outage.

**Vulnerability Assessment Conclusions**

CSU Monterey Bay considers power outages a significant and unavoidable hazard. Power outages that are long-lasting. These outages can and will affect academic and business enterprises, residential life, and university operations.

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. During a power outage, vulnerable populations, especially students with physical disabilities, may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors and locks and lights may impede on a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

CSU Monterey Bay should consider continuing to working with power utility providers, response community and systemwide partners, and stakeholders in planning and mitigating the effects of power outages on the campus and to its community.

**Identified Data Limitations**
CSU Monterey Bay did not report any monetary or life losses due to a power outage.

**Volcano (Associated Air Quality)**

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU Monterey Bay or Monterey County is within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While CSU Monterey Bay does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly...

---

impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as **Low**.

**History of the Hazard**

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California.\(^{11}\) The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.\(^{12}\)

**Potential Impacts of the Hazard**

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Monterey Bay is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Monterey Bay.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

**Probability of Future Occurrence of the Hazard**

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as **Unlikely**.
Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Monterey Bay, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

CSU Monterey Bay is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.
Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain.\textsuperscript{88} These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- Topography – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

\textsuperscript{88} State of California Hazard Mitigation Plan, September 2018
- **Weather** – Weather factors substantially influence the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are aligned to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promoting more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience a decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. CSU Monterey Bay and the City of Seaside are located in northern Monterey County. This region is coastal with significant open fields and hillsides with moderate vegetation proving direct exposures to wildland fire. CSU Monterey Bay is a former Army installation surrounded by open fields containing brush and trees on the east and north sides of the campus and residential neighborhoods to the south. State Route 1 separates the campus from the ocean on the west side of campus.

The CSU Monterey Bay campus is located in the northern side of Seaside bordering the City of Marina. The campus is immediately adjacent to areas of dense trees along 8th Avenue. Gigling Road, Inter-Garrison Road, and 8th Street with other moderate vegetative fuels. The campus has an additional exposure in an open area south of the library and west of the University Center. The typical weather patterns provide an increased humidity to the area of the campus mitigating fire spread potential however, when winds shift offshore conditions can promote fire growth in this area.

The CSU Monterey Bay campus is further surrounded by mountains and extensive areas of fire hazards. Surrounding the Salinas Valley are large mountain ranges including the Coastal Range Mountains, Santa Lucia Range, Santa Cruz Mountains, and the southern end of the Diablo Range. These mountain ranges host state and
national forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the valley in the right wind conditions. The geography of the Salinas Valleys creates a topography that can capture air pollutants including smoke within surrounding mountains and the development of inversion layers. The CSU Monterey Bay campus is located in a region in which wildfire smoke can saturate the air around the campus.

Figure 15-17: Fire Hazard Severity Zones near CSU Monterey Bay

Extant of the Hazard

The area immediately surrounding the CSU Monterey Bay campus is not in proximity to high fire hazard zones. However, CSU Monterey Bay has experienced multiple days of poor air quality due to fires burning in southern California mountains. Given that

the threat to fire directly spreading onto the campus is minimal, the planning committee ranks the extent of the hazard as **Low**.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 15-24: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel -- especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>

</table>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Monterey County also has a long history of wildfire activity. The majority of the historic large fires have occurred in the mountains and foothills surrounding the Salinas Valley. Wildfires occurring in Monterey County have resulted in hundreds of thousands of acres burned and millions of dollars in damages. The campus has a history of wildfire activity occurring within proximity to the campus including the 2020 River Fire.

In addition to the direct exposure to fire, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The CSU Monterey Bay campus has experienced multiple days of poor air quality due to fires burning in southern California mountains. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Monterey County. CSU Monterey Bay personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

Potential Impacts of the Hazard

The location of the CSU Monterey Bay campus along the Pacific Coast is removed from areas with a designated fire hazard, indicating a minimal direct threat of wildfire to the campus. However, as the campus is located adjacent to areas with dense vegetative growth, the potential for wildfires does exist within certain weather conditions. Greater potential impacts from wildfire exist for members of the campus community who reside or work in proximity to fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities

93 Monterey County Multi-Jurisdictional Hazard Mitigation Plan, June 2015
• Damaged or destroyed critical facilities supporting campus emergency support needs
• Loss of community economic base
• Employment losses
• Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
• Agricultural (crops and livestock) damages or destruction
• Environmental damage
• Societal and community impacts
• Damage to organizations and facilities providing support services to vulnerable populations
• Greater evacuation challenges for those most vulnerable
• Psychological impacts of impacted populations
• Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:
• Dangerous levels of air pollution
• Human Health Effects
  • Similar health impacts to pets

• Air conditioning systems overwhelmed
• Greater demands on air filtration systems
• Greater demands on healthcare systems
• Reduced outdoor work productivity
• Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Residential communities along the Wildland Urban Interface may experience extensive damage or destruction in areas the campus community members call home. Utilities feeding areas of Monterey County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. In addition, these locations may be the sites of academic study altering research or generating costs.
Probability of Future Occurrence of the Hazard

Based on the wildfire threat potential in the area surrounding the CSU Monterey Bay campus and large areas of heavy vegetative growth along the south and east sides of the campus, including the immediate proximity to Fire Hazard Severity Zones listed as “Moderate”, the density of residential and commercial development, and the historic occurrences of fires, the probability of wildfire related damage is considered Possible.

Based on the wildfire threat potential in the area surrounding Central California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered Possible.

Vulnerability to the Hazard

The CSU Monterey Bay campus is subject to the direct impact from wildfire due to the campus location adjacent to areas of dense vegetation. However, the typical weather conditions do not promote significant fire growth. The campus is not identified to reside near a designated local High Fire Hazard Severity Zone. The campus is surrounded on three sides by hillside and open lands containing combustible vegetation combined with residential development. Additionally, vulnerabilities to the effects of wildfire would lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillside and extending onto the campus or localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus or in open areas on the campus. These incidents could have significant impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures. Structures with vegetation and other combustibles near the structure increases the ability of fire to spread to buildings. The construction type of buildings on the Monterey Bay campus and the density of the buildings do not promote the ease of fire spread.

Access to the east using Inter-Garrison Road or Reservation Road servicing access to Salinas could become cutoff during fire incidents. Access should remain open using State Route 1 to Monterey or Santa Cruz. However, it is possible for the university to
be limited by these routes for access to and from the campus. Access for supplies, equipment, and emergency services in addition to evacuation away from the campus could be forced to use alternative routes into Seaside.

Some areas of particular vulnerability on the campus includes:

- Fire fuels reduction projects will need to be maintained to adequately protect the campus.
- Many buildings do not have HVAC causing limitations in filtering of air during smoke filled days
- Many buildings use open windows to circulate and cool indoor environments
- Large open areas between campus buildings contain dense vegetation providing opportunities for fire growth in the middle of campus
- The campus childcare center is located removed from the main campus potentially isolated during wildfire events.

The greater concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The past few summers have clearly demonstrated the reality of large wildfires producing enough smoke to fill northern and central California even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Monterey Bay students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU Monterey Bay campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to
remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The risk to wildfire directly impacting the campus is minimal. Costs would be likely be limited to mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $401,286,223. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher. However due to the campus being located in an urban environment, it is unlikely for fire to cause destructive losses.

**Vulnerability Assessment Conclusions**

The occurrence of wildfires has been a frequent event in Monterey County, including wildfire incidents that have threatened or caused damages near the CSU Monterey Bay campus. The location of the CSU Monterey Bay campus in proximity to open hillsides with light to moderate vegetative fuels along the entire eastern edges presents a threat of fire to the campus community and campus assets. Typical weather conditions in Monterey would mitigate this threat however when warm dry
air covers the area there is a potential fire development. The consequences of fires in these areas would present primary and secondary consequences to the CSU Monterey Bay campus and expose vulnerabilities on the campus and to the campus community.

The topography of the valley surrounded by mountains allows for smoke filled air to linger in the valleys of Monterey County area with the potential for unhealthy air quality depending on wind conditions. The standard weather patterns would mitigate this threat however, in offshore wind conditions smoke may be introduced onto the campus from distant locations. Fires in the watersheds of the Monterey County mountains and tributaries may damage vegetation stabilizing hillsides and result in increased sediments to be discharged into the river system and reservoirs reducing their capacity and effectiveness.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Severe Weather (Wind, Tornado, Hail, Lightning)

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or

---

extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

---

96 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU Monterey Bay.

**Regional Climate Influences on Severe Weather across California**

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU Monterey Bay), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.

**Types of Storms in California**

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its

---

101 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php

102 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
strength, characteristics, and the scale of the resulting damage. The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California. These storms affect (in varying degrees) all CSU campuses, including CSU Monterey Bay.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. **Severe thunderstorms** are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.

- **Wind storm**: marked by high wind with little or no precipitation.

---

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.¹¹²

- **Coastal storm**: Large wind-driven waves and/or storm surge that strike the coastal zone.¹¹³

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.¹¹⁴

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.¹¹⁵

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: wind hazards *(including tornadoes)*, hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

Wind Hazards

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\textsuperscript{116} Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” \textsuperscript{117}

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU Monterey Bay).

High Winds, Strong Winds, and Thunderstorm Winds

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\textsuperscript{118}

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\textsuperscript{119}

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50

\textsuperscript{117} Retrieved on 07.15.2021 from https://forecast.weather.gov/glossary.php?word=wind%20gust
\textsuperscript{118} Retrieved on 07.17.2021 from https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf
\textsuperscript{119} Retrieved on 07.17.2021 from https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf
knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\textsuperscript{120}

Please note: \textit{Straight-line wind} is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\textsuperscript{121} However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

\textbf{Tornadoes}

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\textsuperscript{122} This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\textsuperscript{123} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{124}

\textbf{Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.}

\textbf{Santa Ana Winds.} A type of wind hazard that is peculiar to Southern California is called a \textit{Santa Ana Wind}. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{125} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation.

\begin{footnotesize}
\item[121] Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/
\item[122] Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/
\item[123] Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/
\item[124] Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions
\end{footnotesize}
They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{126} (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

Figure 15-19: What Drives a Santa Ana Wind?\textsuperscript{127}

\textbf{Diablo Winds}: The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface

\textsuperscript{126} Retrieved on 07.13.2021 from https://www.weather.gov/safety/wind-mountain-valley

\textsuperscript{127} Retrieved on 07.14.2021 from https://twitter.com/nwslosangeles/status/933049473034579968
pressure gradient that forms in response to an inverted pressure trough that develops over California.\textsuperscript{128}

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.\textsuperscript{129 130 131}

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.\textsuperscript{132} It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the

\footnotesize
\textsuperscript{128} Retrieved on 07.13.2021 from https://www.fireweather.org/diablo-winds

strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.\textsuperscript{133}

\textbf{Lightning}

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\textsuperscript{134}

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{135}

Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

\textbf{Location of the Hazard}

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the CSU Monterey Bay campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

\textbf{Extent of the Hazard}

Severe weather hazards are non-spatial hazards that potentially affect all CSU Monterey Bay campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU Monterey Bay reflect those of the surrounding community and County. As a result, all assets and people at CSU Monterey Bay are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Seaside and Marina areas, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks

the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale (Table below) is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

Table 15-27: **Beaufort Wind Force Scale**

The air is filled with foam and spray. Sea completely white with driving spray; visibility very seriously affected.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{139}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the **date** that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

**Table 15-28: Fujita Tornado Scale (Pre-February 2007)**\(^{140}\)

If this level is ever achieved, evidence for it might only be found in some manner of ground swirl pattern, for it may never be</td>
</tr>
</tbody>
</table>
Table below illustrates the Enhanced Fujita (EF) Scale, currently in use. Tornadoes that have occurred since February, 2007 are classified using the Enhanced Fujita Scale.

Table 15-29: Enhanced Fujita Scale (February 2007 and Later) ¹⁴¹

<table>
<thead>
<tr>
<th>Enhanced Fujita Category</th>
<th>Wind Speed</th>
<th>Potential Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>EF0</td>
<td>65-85 mph</td>
<td>Light damage. Peels surface off some roofs; some damage to gutters or siding; branches broken off trees; shallow-rooted trees pushed over.</td>
</tr>
<tr>
<td>EF1</td>
<td>86-110 mph</td>
<td>Moderate damage. Roofs severely stripped; mobile homes overturned or badly damaged; loss of exterior doors; windows and other glass broken.</td>
</tr>
<tr>
<td>EF2</td>
<td>111-135 mph</td>
<td>Considerable damage. Roofs torn off well-constructed houses; foundations of frame homes shifted; mobile homes completely destroyed; large trees snapped or uprooted; light-object missiles generated; cars lifted off ground.</td>
</tr>
<tr>
<td>EF3</td>
<td>136-165 mph</td>
<td>Severe damage. Entire stories of well-constructed houses destroyed; severe damage to large buildings such as shopping malls; trains overturned; trees debarked; heavy cars lifted off the ground and thrown; structures with weak foundations blown away some distance.</td>
</tr>
<tr>
<td>EF4</td>
<td>166-200 mph</td>
<td>Devastating damage. Well-constructed houses and whole frame houses completely leveled; cars thrown and small missiles generated.</td>
</tr>
</tbody>
</table>

Incredible damage. Strong frame houses leveled off foundations and swept away; automobile-sized missiles fly through the air in excess of 100 m (107 yd); high-rise buildings have significant structural deformation; incredible phenomena will occur.

Based on the extent ranking factors identified (above), the planning committee ranks the extent of tornados as **LOW**.

**Extent: Hail**

The National Oceanic and Atmospheric Administration and the Tornado and Storm Research Organization (TORRO) have combined efforts to create the Hailstorm Intensity Scale. Table below provides details of this scale.

Table 15-30: Combined NOAA/TORRO Hailstorm Intensity Scale\(^{142}\)

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the hail hazard as **LOW**.

**Extent: Lightning**

The National Weather Service (NWS) uses a Lightning Activity Level (LAL) scale to indicate the frequency and character of cloud-to-ground (C/G) lightning. The scale uses a range of 1 – 6, with 6 being the high end of the scale. Table below provides details of the LAL scale.
Table 15-31: Lightning Activity Level (LAL) Scale\textsuperscript{143}

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no established, objective severity scale for thunderstorms.\(^{144}\) \(^{145}\) That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light*, *medium*, or *heavy* according to following five (5) characteristics:

\(^{144}\) Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

\(^{145}\) Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
the nature of the lightning and thunder;
the type and intensity of the precipitation, if any;
the speed and gustiness of the wind;
the appearance of the clouds; and
the effect upon surface temperature.\textsuperscript{146}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- \textbf{Airmass Thunderstorm}: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{147}
- \textbf{Frontal Thunderstorm}: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{148} or
- \textbf{Squall-line Thunderstorm}: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder). \textsuperscript{149 150}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as \textbf{LOW}.

History of the Hazard

Severe weather hazards have been an annual occurrence in Monterey County and on the CSU Monterey Bay campus. Historical data for these hazards are presented below.

Historical Storm Data Collection: NCEI Storm Events Database

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA's National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type. For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events. To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Monterey County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind**: at least 52 events, or approximately 2.05 events per year

---

155 National Climatic Data Center. Storm Events Database. Retrieved 07.30.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType%28Z%29+High+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=202
- **Strong Wind:** at least 115 events, or 4.54 events per year<sup>156</sup>
- **Thunderstorm Wind:** at least 7 events, or approximately 0.28 events per year<sup>157</sup>
- **All Wind Hazard events** (excluding Tornadoes): at least 168 events, or approximately 6.63 events per year.<sup>158</sup> (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Monterey County, there have been at least 168 wind hazard events since 1996, excluding tornadoes.<sup>159</sup> That translates to an approximate average historical frequency of occurrence of 6.63 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 174 events) and simultaneous Database searches of all severe weather hazard events (i.e., 168 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind”

or “Hail” that are reported for Monterey County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{160}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 168 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Monterey County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Monterey County has experienced since 1996 have been costly. There have been 1 death and 1 injury, and property damage estimates have totaled approximately $1,600,000; however, there has been no reported crop damage.\(^{161}\)

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there has been one (1) reported event of a tornado in Monterey County, which translates to approximately 0.04 tornado events per year.\(^{162}\) The reported severity rating of the lone tornado is EF0.\(^{163}\)

**Historical Tornado Hazard Losses for Monterey County since 1996**

According to the NCEI Storm Events Database, the one (1) tornado hazard event that Monterey County has experienced since 1996 has produced no deaths or injuries, and has generated no property or crop damages.164

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 20 reported events of hail in Monterey County, which translates to approximately 0.79 hail events per year.165 (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 21 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Monterey County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Monterey County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Monterey County has experienced since 1996 have been minimal. There have been no deaths or injuries, and property and crop damage estimates have totaled approximately $60 and $50, respectively.166 (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Monterey County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there has been one (1) reported event of lightning in Monterey County, which translates to approximately 0.04 lightning hazard events per year.\textsuperscript{167}

**Historical Lightning Hazard Losses for Monterey County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Monterey County has experienced since 1996 have produced no deaths or injuries, and have generated no property or crop damage.\textsuperscript{168}

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

Information obtained from the NCEI Storm Events Database indicates that there have been 190 occurrences of the severe weather hazard in Monterey County. This translates to 7.50 severe weather hazard occurrences per year.\textsuperscript{169}

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 197 events) and simultaneous Database searches of all severe weather hazard events (i.e., 190 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado;” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Monterey County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{170}

When such a discrepancy arises, the more conservative aggregate hazard wind event

\begin{itemize}

value (i.e., 190 events) is used to determine the historical frequency of occurrence for the
severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Monterey County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Monterey
County has experienced since 1996 have been costly. There have been 1 death and 1
injury, and property and damage estimates have totaled approximately $1,600,000 and
$50, respectively. However, it is important to note that for all Monterey County severe
weather hazard events recorded on the Storm Events Database, all deaths, injuries, and
property damage have been caused by wind hazard events alone.

**Wind Hazards Not Included in the NCEI Storm Events Database**

**Santa Ana Winds**

Santa Ana wind events occur at least twice per month from October through April. From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the
Southern California region, yielding an average of 32 occurrences per year. Typical Santa
Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting
up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up
almost entirely of events lasting between 7 and 12 days.

Figure below shows the mean monthly frequency per season of Santa Ana Wind events
detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and
are defined as those events that are above the 90th percentile of all events on record.

Figure 15-20: Mean Annual Frequency of Santa Ana Wind events (1948-2012)

---

171 National Climatic Data Center. Storm Events Database. Diablo Winds

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\textsuperscript{177}

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{178}

\textsuperscript{178} Retrieved on 07.15.2021 from https://www.fireweather.org/diablo-winds
Sundowner Winds

Strong sundowner wind events occur approximately 2-3 times per year. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within CSU Monterey Bay campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU Monterey Bay campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

The only severe weather hazard that is significant enough to be profiled in the 2016 Monterey County Multi-Jurisdictional Hazard Mitigation Plan (MJHMP) is the “Windstorm” hazard; tornadoes are not considered to be significant hazards for the
County and therefore are not profiled.\textsuperscript{181} (According to the MJHMP, a “windstorm” is a strong wind event either from cyclonic systems and their cold fronts in the winter, or from thermally forced circulations during the spring/summer months (i.e., sea breezes)). Windstorms are considered to be hazards that have a medium significance for the County; areas of wind hazard susceptibility (and therefore potential impact) within the County differ between the winter and spring/summer months, spreading the impact of the hazard across the year.\textsuperscript{182} As a result, wind hazards are considered to have a moderate potential impact on the County and (by extension) the CSU Monterey Bay campus. Because tornadoes are not considered to be significant hazards for the County, they have minimal potential impact on the County and (by extension) the CSU Monterey Bay campus.

\textbf{Hail}

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

The 2016 Monterey County Multi-Jurisdictional Hazard Mitigation Plan does not explicitly profile hail, as it is not considered to be a significant severe weather hazard event in Monterey County. As a result, hail hazards are considered to be of low significance, and therefore to have a minimal potential impact on the city and (by extension) the CSU Monterey Bay campus.\textsuperscript{183}

\textbf{Lightning}

Lightning strikes the United States about 20-25 million times a year.\textsuperscript{184} Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.\textsuperscript{1} Property losses due to lightning have been very costly...

\begin{itemize}
  \item \textsuperscript{184} Retrieved on 07.21.2021 from https://www.elcosh.org/document/4154/d001459/OSHA+NOAA+Fact+Sheet%253A+Lightning+Safety+When+Working+Outdoors.html
\end{itemize}
across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.ii (Commercial claim payouts for lightning losses for the U.S. were not available.)

The 2016 Monterey County Multi-Jurisdictional Hazard Mitigation Plan does not explicitly profile lightning as a significant severe weather hazard event in Monterey County, although it is included as a causal event for wildfire hazards. As a result, lightning hazards are considered to be of low severe weather significance, and therefore to have a minimal severe weather potential impact on the city and (by extension) the CSU Monterey Bay campus.iii

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The 2016 Monterey County Multi-Jurisdictional Hazard Mitigation Plan states that there is between 10% and 100% chance that “Windstorm” hazards (i.e., wind hazards, excluding tornadoes) will occur in the future, and that its probability of future occurrence is “likely.”iv However, according to the NCEI Storm Events Database, wind hazards have occurred in Monterey County far more than once annually – an average of 6.63 times per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Monterey Bay campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU Monterey Bay campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both 2016 Monterey County Multi-Jurisdictional Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU Monterey Bay campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU Monterey Bay is **HIGHLY LIKELY**. See Table below for probabilities of future occurrence for component severe weather hazards for the City/County and the campus.

Table 15-33: Severe Weather Hazard Probabilities of Future Occurrence for Monterey County and CSU Monterey Bay

<th>Probability of Future Occurrence</th>
</tr>
</thead>
</table>

15-154
Vulnerability to the Hazard

People, structures, and assets on the CSU Monterey Bay campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The CSU Monterey Bay campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire CSU Monterey Bay campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within the CSU Monterey Bay campus are at risk from severe weather. There are approximately 122 buildings that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $401,286,223 for 89 of the buildings, and unknown for the remaining 33 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is not currently available, though CSU leadership may pursue such data in the future.

** Note: The Diablo and Sundowner wind hazards are not present in Monterey County, and therefore are not rated for probability of future occurrence. They are included here for information purposes only.
The population at the CSU Monterey Bay campus varies throughout the day. As of Fall, 2019, CSU Monterey Bay had 7,123 students and 1,059 faculty and staff. All are at risk from severe weather events, with 8,182 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to the CSU Monterey Bay campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU Monterey Bay.

It is evident that the CSU Monterey Bay campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
15.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Monterey Bay campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
### Table 15-34: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
</table>
| Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning? | ▪ Employees in rented employee housing  
▪ Disabled students and employees  
▪ Populations experiencing homelessness |
| Which population groups are most difficult to reach in an event?          | Partners who lease or rent facilities on campus                                   |
| Which population groups have little/limited support networks if impacted by an event? | ▪ Students and employees’ staff with access and functional needs  
▪ Populations with mental health needs  
▪ Students in the area alone |

**Resilience Variables Related to Campus Emergency Management**

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:
- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- In some important areas there were disagreement in the answers.
- “Response Averaging” was used in the Table X: Issues of Concern and Inclusion in Emergency Management Plans and Processes to address disagreements.
- Food issues are the largest issues besides homelessness and financial. Need a generator in the cafeteria but permits for backup power is a huge issue.
- Health and wellness are in the plan for mass casualty instances and satellite locations; will make it more robust. Director of the health and wellness services serves as the IMT and is in the EOC.
- Ken Folsom is on the county AFN committee; AFN is incorporated it into the entire plan for communications and response. Have two positions as a tech specialist (with JOS/check lists) as AFN coordinators for any event to make sure it is in everything they do.
- For racial equity, they have a tight incident management team; as part of NIMS, they can pull anyone in to the IMT if having a student impacted to make sure to address issues. Not mentioned in the EOP, more in the plans but don’t want too much in the plans as they respond to everybody and don’t think this is a necessity.
- Social media plays a huge part in the plans and getting the message out. They have a few buildings on campus with no cell phone coverage (cell phone and text messages) – if so, will get an email. Looking at ALERTUS SYSTEM to interrupt the tv, cable. The gap needs to be filled in some areas of campus. access to outside of building PA SYSTEM – not designed to be heard in the building that is on the system. Must tie the computers into the network.
- International programs played a huge part in the onset of notifying the international students and have the director as part of the IMT. They do a great job and be more involved in that. Have worked with the state dept. While not in the EOP, they plan to expand this section.
- Immigrants and those with immigration status issues (undocumented, DACA, etc.) and related diverse populations are afraid. While not addressed in the EOP, the objectives of Residential Life address it in the shelter objectives.
- They don’t address LGBTQI issues directly as the plan is considered a whole community plan.
- Transportation dependency is an issue East campus because there is a large population of families living there and an issue if they must evacuate the east campus. Have an operational plan for evacuation in the EOP; especially noted the wildfire threats.
Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

Drought

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\(^{185}\) Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\(^{186}\) Fresh water supplies are predicted to be full of extremes, with both droughts and extreme

---

precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.\(^{187}\)

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and

decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children.

---

Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

16.1 University Profile

University History

In the fall of 1956, the San Fernando Valley campus of the Los Angeles State College of Applied Arts and Sciences was established on the present site of California State University, Northridge. California Legislative action in 1958 decreed that the campus would separate from its parent college (on July 1, 1958) to become San Fernando Valley State College. During the 1960s and into the early 1970s, San Fernando Valley State College evolved from a collection of temporary buildings into a true college campus. On June 1, 1972, San Fernando Valley State College was renamed California State University, Northridge (CSUN, for short), by action of the California Legislature and the Board of Trustees of the California State University. CSUN continued to grow both in enrollment and in academic offerings throughout the 1970s, 1980s, and early 1990s.

CSUN faced its greatest challenge as an institution when a devastating 6.7-magnitude earthquake struck the Northridge area on January 17, 1994, heavily damaging CSUN facilities. Numerous buildings on campus, including the University Library, suffered severe damage, and one of the parking structures collapsed entirely. In addition, the South Library was condemned and later demolished. However, the spring semester of that year began after a delay of only two weeks, with temporary buildings set up to conduct regular classes during the reconstruction effort. The library was restored to service by the fall of 1994, though the east and west wings had to be completely rebuilt and did not regain full service until the fall of 2000. Post-earthquake recovery concluded with the construction of the new Administration Building, University Hall, in 2003.

Today, CSUN is one of the largest campuses of the 23-campus California State University system. CSUN’s commitment to student success, inclusivity, and community involvement has gained notoriety for the university, and CSUN has been designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.
CSUN’s university governance also includes five (5) campus divisions and twenty-one (21) university-level advisory committees. The advisory committees must fulfill at least one of the following criteria:

1. Serves as a standing advisory committee to the president
2. Addresses a CSU directive, executive order, or other state requirement
3. Serves in a community relations capacity

University Mission

“California State University, Northridge exists to enable students to realize their educational goals. The University’s first priority is to promote the welfare and intellectual progress of students. To fulfill this mission, we design programs and activities to help students develop the academic competencies, professional skills, critical and creative abilities, and ethical values of learned persons who live in a democratic society, an interdependent world, and a technological age; we seek to foster a rigorous and contemporary understanding of the liberal arts, sciences, and professional disciplines, and we believe in the following values.”

CSU Northridge highlights core values fundamental to the University’s success; Commitment to Teaching, Scholarship, and Active Learning, Commitment to Excellence, Respect for All People, Alliances with the Community, and Encouragement of Innovation, Experimentation, and Creativity.

University Location

CSUN is located in Northridge, a neighborhood of Los Angeles. The campus is approximately 25 miles northwest of Downtown Los Angeles, near the geographic center of the San Fernando Valley.

University Population

CSUN has a total enrollment of 38,815 undergraduate and graduate students combined. The full-time enrollment is 33,093 students and the part-time enrollment is 5,722 students.

The enrolled Fall 2020 student population at CSUN, both undergraduate and graduate, is 54.2% Latinx, 22.1% White, 9.4% Asian American, 4.6% African American, 2.9% Two or More Races, 0.1% American Indian or Alaska Native, and 0.1% Native Hawaiian or Other Pacific Islanders.

The most popular Bachelor’s Degree concentrations at CSUN are General Psychology, Sociology, and General Business Administration & Management. CSUN is primarily a commuter campus.
16.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate ..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

16.3 Hazard Identification and Risk Assessment

Overview of California State University, Northridge History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA)
maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 16-1 (following).
Table 16-1: Hazard Identification Determinations

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- Highly Likely- 76%-100% that the hazard would occur annually.
- Likely- 50%-75% that the hazard would occur annually.
- Possible- 11%-49% that the hazard would occur each annually.
- Unlikely- 0%-10% that the hazard would occur each annually.
**Communicable Disease**

**Description of the Hazard**

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 16-2 below.)

Descriptions of Identified Communicable Disease Hazards at CSUN (Northridge) CSU Northridge (CSUN) has identified two (2) communicable disease hazards that have had the greatest impact on campus – COVID-19 and Measles. The following are brief descriptions of the communicable disease hazards at CSUN.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.
The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.⁵

**Measles**

Measles (also known as rubeola) is a highly contagious childhood infection caused by a virus. The measles virus replicates in the nose and throat of an infected child or adult. Then, when someone with measles coughs, sneezes or talks, infected droplets spray into the air, where other people can inhale them. The infected droplets may also land on a surface, where they remain active and contagious for several hours. The virus is contracted by putting touching one’s nose, mouth, or eyes after touching the infected surface.

Measles can be serious and even fatal for small children. The disease still kills more than 100,000 people a year worldwide, most under the age of 5. However, as a result of high vaccination rates in general, measles hasn’t been widespread in the United States for more than a decade.⁶

**Location of the Hazard**

Communicable diseases have the potential to affect the entire CSUN (Northridge) planning area equally. As a result, the communicable disease hazard can be found at the CSU Northridge (CSUN) campus, located in the Northridge neighborhood of the

---

City of Los Angeles (Los Angeles County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) students, faculty, and staff at CSUN are at risk of exposure to the communicable disease hazard.

**CSU Student Housing Locations and Populations**

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For CSUN, approximately 8% of its 38,391 enrolled students (or 3,071 students) reside in student housing.

**Extent of the Hazard**

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 16-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.
The Extent of CSUN (Northridge) Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Measles at CSUN (Northridge). Measles would be classified at the BSL-2 containment level. (Source: Stanford University Environmental Health and Safety. 8

The Extent of CSUN (Northridge) COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3. 9

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to June 7, 2021, there were a reported 272 cases of COVID-19 at CSUN. Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a

---

result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 16-5 and 16-6 show campus-level and County-level COVID-19 Case data for CSUN (Northridge). These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system (including the CSUN campus). The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSUN students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic, and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSUN) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

### Table 16-6: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 16-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases that fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

---

Table 16-7: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>

<td>Other Hemorrhagic Diseases</td>
</tr>
</tbody>
</table>

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

### Probability of Future Occurrence of the Hazard

There have been cases of a variety of communicable disease throughout the CSU system, including COVID-19 (SARS-CoV-2), Meningitis, Measles, Influenza (Including H1N1/Swine Flu), Tuberculosis, Norovirus, Mumps, E. Coli, and Sexually Transmitted Diseases (STDs). However, there are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.
Table 16-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 16-8: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence. Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at CSU campuses. CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, CSU - Northridge had 38,391 students and additional faculty and staff.)\(^{15,16}\) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic at CSUN.

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSUN) are at risk of developing an extreme

\(^{15}\) The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

\(^{16}\) The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
incidence of COVID-19, and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 16-2 below for the economic impact to the SJSU campus). Several CSU campuses saw refund losses surpass $10 million. (See Figure 16-2.)

Figure 16-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs

---

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 16-11.) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

</table>
Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. *If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time.* This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 16-12 below for the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus
shutdowns, educational disruption, and economic harm to the CSU system (including CSU Northridge). In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Dam and Levee Failure**

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to
furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from over toppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

Los Angeles County is home to a variety of flood control facilities and levee systems mostly along the base of the various mountains and hills throughout the county. Levees have been constructed along numerous flood control channels providing community protection. The CSU Northridge campus is in general proximity to dams along the Los Angeles River and tributary systems in addition to flood control channels lined with levees within the San Fernando Valley.

There are a number of dam facilities along the base of the Santa Monica, Santa Susana, San Gabriel, and Verdugo Mountains and along the river systems extending from the mountains. The larger facilities include the Los Angeles Reservoir, Lower San Fernando (Van Norman) Dam, Chatsworth Dam, and Encino Dam. Each of these facilities regulate water flow into the San Fernando Valley and Los Angeles River systems. The CSU Northridge campus lies outside of dam inundation zones for these facilities.

Figure 16-4: Lower San Fernando Dam Breach Inundation Map\textsuperscript{25}

\textsuperscript{25} California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
A number of flood control systems feed into the Los Angeles River from the mountains and San Fernando Valley. The Aliso Canyon Wash is a flood control channel ½ mile west of the campus. The channel extends from the Santa Susana Mountains north of campus to the Los Angeles River in the southern portions of the San Fernando Valley. The campus is identified as being located within the levee protected zone from the Aliso Canyon Wash. This zone covers the entire campus with the exception of the southeast corner including Jeanne Chisholm Hall, Monterey Hall, and the G3 Parking Structure.

The Bull Creek channel is an additional flood control channel that is located approximately 1 ½ miles east of the campus. The 7-mile channel feeds into the Los Angeles River at the Sepulveda Basin. The channel drains the Los Angeles and Lower San Fernando Reservoirs. The CSU Northridge campus is not within a flood protected zone for Bull Creek.

Extent of the Hazard
Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

The CSU Northridge campus lies outside of the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the CSU Northridge campus is expected to remain out of the inundation area. The inundation area is expected to spread water in areas to the east and south from the campus. Additionally, there are multiple transportation corridors that lie within the dam inundation zones that could compromise access, evacuation, and supply routes. The inundation areas have the potential to threaten areas the campus community reside or work. Primary impacts to the campus would be disruption of transportation routes and potentially the interruption of campus operations. Based on these factors, the planning committee ranks the extent of the hazard as **Low**.

**Extent – Levee Failures**

---

16-29
Levees are used along numerous flood control channels and other waterways including the Los Angeles River and Aliso Canyon Wash. The CSU Northridge campus lies within the levee flood protected area of the Aliso Canyon Wash. In the event any of these channels were flowing at elevated levels and a failure of a levee were to occur, the campus and community surrounding the campus would likely experience flood related damages. This specific hazard could alter the ability of the campus to maintain operations as damages would be extensive. Depending on the location of a breach, the campus community would be heavily affected with the loss of life and homes, access to campus would be limited, and student financial capacity to support ongoing education being diminished. Based on these factors, the planning committee ranks the extent of the hazard as Moderate.

History of the Hazard

There are no records of dam of levee failures in areas that present a threat to the CSU Northridge campus. Los Angeles County has experienced the following dam failures:

Table 16-13: Los Angeles County Dam Failures

<table>
<thead>

</tr>
<tr>
<td>12/14/1963</td>
<td>Baldwin Hills</td>
<td>770af</td>
<td>277 residences, 5 fatalities</td>
</tr>
</tbody>
</table>

In addition to the above incidents, the February 11971 San Fernando Earthquake caused significant damage to Lower San Fernando Dam (Van Norman Dam). At the time of the earthquake, the reservoir was half full, containing approximately 5,500-acre feet of water. The intense shaking resulted in the top 30 feet of the dam edifice crumbling, with water only six feet from the top. The dam did not fail but expected heavy after-shocks required rapid pumping, de-watering operations, and the evacuation of 80,000 people. This facility is 4 miles away from the CSU Northridge campus.

Potential Impacts of the Hazard

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:
- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

**Levee Failure Impacts**

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

**Probability of Future Occurrence of the Hazard**

Los Angeles County is determined to be at risk from dam and levee failure in many parts of the county. The location of the CSU Northridge campus downstream from the Van Norman Reservoir Complex and in proximity to Aliso Canyon flood control channel along demonstrates that the potential exists for future dam and levee related issues. Much of the San Fernando Valley resides within the dam inundation zone for
the Van Norman Reservoir. However, the campus remains outside of and to the west of the inundation zone. Levees protecting the Aliso Canyon Wash flood control channel are located ½ of a mile west of the campus. The campus resides within the levee protected zone for Aliso Canyon. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on no historical experience of levee failure for this levee, and recognizing the regulations, inspections, monitoring and maintenance in place, the likelihood of this hazard is low.

The probability of future occurrence for both dam and levee failures is Unlikely.

Vulnerability to the Hazard

Given high priority monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. In addition, the campus does not lie within an inundation zone. As such, the campus is not considered to be truly vulnerable on a daily basis. However, in the unlikely event of a catastrophic failure, the effects of flooding from compromised dams and levees on campus would most likely be limited to indirect or secondary effects in terms of disruption to regional transportation networks and services, and the amount of time to respond to the needs of the campus community prior to inundation will be limited.

Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations in the event of a low probability, catastrophic event.

Vulnerability to a dam or levee failure on the CSU Northridge campus will vary depending on the degree of breach or structural failure and when the failure were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses
Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $550,272,157. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU Northridge.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the CSU Northridge campus, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences would be catastrophic to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.
Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.

**Drought**

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.
- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - Northridge) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified throughout Los Angeles County where CSU - Northridge is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.  

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout Los Angeles County which surrounds the planning area and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies.

In addition, although drought affects the entire CSU system wide planning area, the potential impacts are variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction.

Also, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels in California have been measured up to 30-feet with subsidence bowls covering hundreds of

---

square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Such impacts have not occurred on campus but remain issues of concern over the long term.

For CSU – Northridge, the extent of the hazard is Low (corresponding to D0-D1 on the extent scale below). However, the campus planning committee recognizes that the potential for more severe conditions exists and is tied to regional water resource vulnerabilities.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

</table>
History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous. Los Angeles County has experienced 6 or more periods of drought covering over 12 years from 2000-2021, which includes the CSU - Northridge footprint. Though drought occurrences are not identified specifically for the campus, the planning committee reports intermittent drought-related air quality issues.

Figure 16-5: Periods of Drought in Los Angeles County, CA, 2001 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

---

30 NCEI. Storm Events. Retrieved 5.4.2021 from: [https://www.ncdc.noaa.gov/stormevents](https://www.ncdc.noaa.gov/stormevents)
According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 31

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 16-5: Periods of Drought in State of California, 2001 – 202132

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on Los Angeles County where the CSU - Northridge campus planning area is located:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report

calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent. 

**Potential Impacts of the Hazard**

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that although historic impacts on campus have been minimal, the potential impacts throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the CSU - Northridge campus planning area is a reduction in water availability for the municipal area tied to each campus. Other potential impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - Northridge to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of any agricultural research crops and/or field stations. Though water resources remain stable for the campus, the planning committee reports that the campus utilizes sustainable, drought tolerant landscaping to minimize potential water source or use limitations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. However, the wildfire hazard is analyzed separately in this plan. (See wildfire section).

In reviewing the occurrences of drought for Los Angeles County (surrounding the CSU – Northridge footprint), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2014-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - Northridge, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus; however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area. 35

At present, drought related damage to campus buildings and infrastructure at CSU - Northridge has not been reported, but the potential for such impacts is possible over the long term. With regard to overall potential impact, water supply/availability for CSU - Northridge is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Northridge. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Probability of Future Occurrence of the Hazard

Highly Likely — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that CSU - Northridge lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

---

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Northridge campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - Northridge planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. 37 In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir. 38

Vulnerability of Populations

Drought vulnerabilities include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerability measures apply to the students, faculty and staff of the CSU - Northridge campus.

Property Vulnerability

Drought vulnerabilities include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerability measures apply to the properties of the CSU - Northridge campus.

Natural Environment Vulnerability

The historical and potential impacts of drought on the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerabilities on campus and throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping. 39

Critical Facilities Vulnerabilities

CSU - Northridge’s critical facilities’ vulnerabilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

Estimate of Potential Losses

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of Northridge, County of Los Angeles, and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

Vulnerability Assessment Conclusions

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

Identified Data Limitations

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

Fault Rupture – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

Liquefaction – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.
**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU Northridge is located in the eastern portion of the Los Angeles Basin. In general, fault systems surround and traverse through Los Angeles and Orange Counties including the area of CSU Northridge. Throughout the basin the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 30 miles northeast of the CSU Northridge campus. In addition to the San Andreas Fault, Los Angeles County is home to or near additional fault systems with the potential to generate strong ground shaking. The Northridge Hills is a fault close to the CSU Northridge campus crossing to the northwest just beyond the northern boundary of the campus. The Santa Susana Fault extends across the base of the Santa Susana Mountains in an east to west direction 4 miles north of the campus. The Sierra Madre Fault is 8 miles east of the campus running along the base of the San Gabriel Mountains. The Hollywood-Raymond Fault is another east to west fault 13 miles south of the campus connecting Arcadia and Beverly Hills. The Northridge Fault extends in a northwest direction from Kagel Canyon through Santa Clarita 8 miles northeast of the campus. The Verdugo Fault extends from South Pasadena northwest to San Fernando 7 miles to the east of the campus. There are numerous additional faults in the area on all sides of the campus.
The CSU Northridge campus is located outside of areas designated to be liquefaction zones. No campus facilities are located within the liquefaction zone. However, substantial areas of the community to the south and east of the campus do reside within the liquefaction zone. This also includes major transportation corridors including Interstate 5, Interstate 405, US Highway 101, State Route 134, State Route 170, Reseda Blvd., Roscoe Blvd., and the Southern Pacific Railroad. The liquefaction zone generally follows the base of the Santa Monica Mountains.

Figure 16-7: Liquefaction Zones in Proximity to CSU Northridge

---

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity, and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released. The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording.
of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the
The magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 16-8: Earthquake Magnitude and Equivalent Energy Release

Numerous fault systems surround and traverse the areas surrounding the campus. Though the campus is not in a liquefaction zone, such zones are located near the campus. In addition, several severe and catastrophic events have taken place in the region, in particular the Northridge event in 1994. Based on these factors, the planning committee ranks the extent of the hazard for the campus as Moderate to High.

History of the Hazard

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Los Angeles County also has a long history of earthquake activity. The entire area of Los Angeles County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The January 9, 1994 Northridge Earthquake became the costliest seismic event in California history. The earthquake caused extensive damage to structures, the transportation infrastructure, utility systems, water storage, communications, and critical facilities. This level of damage due to the fault that ruptured was directly underneath a densely populated urban area. The Northridge Earthquake was found to raise the nearby mountains by as much as 70 centimeters. The earthquake was provided a federal disaster declaration (DR-1008).

The October 1, 1987 Whittier Narrows Earthquake shook a large part of southern California. The earthquake caused $358 million in damages, especially in the Alhambra, Pasadena, and Whittier areas. The earthquake resulted in extensive infrastructure damages, multiple injuries, and 8 fatalities. The earthquake was provided a federal disaster declaration (DR-799).

The February 9, 1971 Magnitude 6.5 San Fernando Earthquake struck the San Fernando Valley in Los Angeles just after 6am. The intense shaking caused the collapse of freeway overpasses, hospitals, and other infrastructure. It damaged thousands of homes and businesses, a reservoir, and critical infrastructure. 65 people were killed and 2,000 more were injured. The shaking was felt for 300 miles including in Las Vegas, Nevada. The earthquake was provided a federal disaster declaration (DR-299).

43 2019 County of Los Angeles All-Hazards Mitigation Plan, 2019
The March 10, 1933 Long Beach Earthquake registered at a Magnitude 6.4 occurred along the Newport-Inglewood Fault. The earthquake resulted in over $50 million in damages, 500 injuries, and 120 fatalities. Unreinforced masonry structures were the source of most of the casualties. 70 schools were destroyed and 120 were damaged. This earthquake promoted statewide standards in building design and construction for schools and other structures to better withstand seismic events.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils to the south and east of the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Los Angeles area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Northridge could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Northridge could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader San Fernando Valley and Los Angeles County region limiting immediate assistance that the campus may normally expect.

Local impacts to CSU Northridge campus caused by an earthquake could include:

- Damage and secondary fires to industrial buildings to the west of the campus
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway system
- Damages to rail lines and rail cars ½ mile to south of campus
- Structural damage to bridges over waterways and flood control channels
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Damages to homes and apartment complexes surrounding the campus and throughout the San Fernando Valley
- Structural damage to Aliso Canyon Wash levees
- Damage to flood control and drainage systems including the Lower San Fernando Dam
- Structural damage to campus academic and support buildings
- Structural damages to parking structures
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Los Angeles County fault systems surrounding Los Angeles and San Fernando Valley is included in the following table.

Based on the earthquake shaking potential in the San Fernando Valley and Los Angeles Basin, the proximity to the above listed fault systems, the probability of seismic ground shaking generating damage is considered **Possible**.

**Vulnerability to the Hazard**

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of CSU Northridge places the campus in an urban/suburban community near residential, commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to the San Fernando Valley generally surround the area and some cross into the city including near the CSU Northridge campus. For example, the Northridge Hills Fault traverses the northern edge of the campus. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the CSU Northridge campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the city. This would particularly be seen with greater damages to unreinforced masonry buildings.
The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. Roadways surrounding the campus providing critical access to and from the campus will likely become heavily congested in a major earthquake. As the CSU Northridge campus is downstream from dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions. Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $550,272,157.
Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $550,272,157.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater Los Angeles Basin, San Fernando Valley, and the CSU Northridge campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU Northridge campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding Northridge, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Los Angeles Basin and San Fernando Valley region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.
Vulnerabilities will be seen in the physical infrastructure on the campus and the human population of the campus community. Campus infrastructure is vulnerable to severe shaking particularly in areas where the ground is loose or susceptible to liquefaction. Specifically older buildings, masonry constructed buildings, and other structures susceptible to shaking related damage are the most vulnerable. Communication systems, computer networks, and other electronic systems may be vulnerable when overwhelmed by increased demand during emergencies or by shaking related damages. The people of the campus community are vulnerable to effects of intense shaking in the form of injuries from falling debris, exposure to secondary floods or fires, loss of employment, extreme disaster induced stress, and loss of access to critical services or social contacts.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Erosion

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another”. Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable.

Location of the Hazard

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across those areas of the campus with erosion-prone characteristics. In the future, campus leadership may investigate whether or not and to what extent specific erosion prone locations are present on the campus.

Extent of the Hazard

There is no published scale of severity or extent for this geologic hazard. If conditions are favorable, erosion is likely to occur. Based on no history of occurrence and no known erosion prone locations, the planning committee ranks its extent on campus as Low.

History of the Hazard

There have been no recorded incidents of erosion on the CSU Northridge campus.

Potential Impacts of the Hazard

Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, the probability of at least a limited degree of erosion occurring somewhere on the campus in the future is high over the long term.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Northridge infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion.
In the wider Northridge community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.
Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

Vulnerability Assessment Conclusions

While the ability to predict future erosion on the CSU Northridge campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

Extreme Temperatures (Includes Extreme Cold and Extreme Heat)

Description of the Hazard (Extreme Heat)

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.  

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air. As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails,
and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

Location of the Hazard

Extreme heat events are a non-spatial hazard, and may occur throughout the CSU Northridge (CSUN) campus.

Extent of the Hazard

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the low 80s to the low 90s in the Northridge area of Los Angeles County. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at the CSUN campus was 113°F on July 22, 2006. This high temperature was related to an extended period of excessive heat affecting San Luis Obispo, Santa Barbara, Ventura, Los Angeles, and many other Southern California counties. Heat index values ranged from 100°F to 119°F. Given over 200 extreme heat days from 1990-2015, the planning committee ranks the extent of the hazard as **Moderate** – the rare occurrence of humidity coinciding with such frequently high temperatures reduces the hazard ranking from rising above Moderate.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100°F – 104°F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105°F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach those criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 16-9 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

---

As the heat index rises, so does the potential danger to people and animals. Table 16-22 (following) shows the health hazards associated with extreme heat.

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been five excessive heat events in Los Angeles County since 2007. These events were grouped together as part of the same heat waves.

**August 30, 2007; September 1, 2007; September 3, 2007:** A combination of high temperatures and high humidity produced an extreme heat event across Southern California. Heat index values ranged from 105° to 112° F. There were eight deaths attributable to this excessive heat event.

**June 20-21, 2008:** During this large-scale heat wave that impacted much of the state, afternoon high temperatures climbed as high as 114° F. The heat resulted in several power outages due to excessive electrical use.

**Note:** The NCDC database also lists more than 200 additional dates that the recorded temperature at the CSUN campus has reached 100° F or greater between 1990 and 2015.

Potential Impacts of the Hazard

CSUN may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

According to NCDC and NCEI data, Los Angeles County has experienced over 200 days with temperatures above 100 degrees from 1990-2015. This translates to 8 extreme heat events per year over the 25-year period. Therefore, using the scale provided, it is **Highly Likely** that the hazard will occur annually, though only **Possible** for extreme heat to be accompanied by high humidity levels. The City of Los Angeles, of which Northridge is a part, does not consider extreme heat to be a primary hazard, because the combination of high temperature and high humidity, which are the
Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result. This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

CSUN is aware of the potential for extreme heat events, and in particular, for the potential for the frequency of these events to increase. The campus will issue its own heat warnings (in addition to any warning issued by the City of Los Angeles) for students’ safety. When it comes to staff safety, supervisors are reminded of Occupational Safety and Health Administration (OSHA) regulations that protect workers from extreme heat. Under OSHA law, employers must provide workplaces free of known safety hazards, which includes protecting workers from extreme heat, and any employer with workers exposed to high temperatures should establish a heat illness prevention program that includes monitoring workers for signs of illness and providing them with water, rest, and shade. The campus also issues alerts and information about the warning signs for heat-related illnesses. These warnings are communicated through the student health office.

CSUN monitors power usage to ensure that air-conditioning is running in campus facilities during hot days. The campus has experienced broken air-conditioning units and has installed a few back-up generators to keep the campus population cool. Some units are portable and can be moved to various buildings as needed.

Therefore, although this is not a hazard that the campus should experience with regularity, CSUN has ample preparation in place to handle the risks and vulnerabilities.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the CSUN campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.\textsuperscript{58}

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

\textit{Flood}

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water

bodies that are subject to flood events. Flooding is a naturally occurring event that becomes hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding represents one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other features may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.
- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected. This hazard is addressed in Section XX

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric Rivers**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California, they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Location of the Hazard

CSU Northridge is located in the San Fernando Valley portion of Los Angeles. The San Fernando Valley is surrounded by mountainous terrain on all sides. The Los Angeles River begins in the San Fernando Valley on west side where the Arroyo Calabasas and Bell Creek join. There is an extensive network of flood control channels that drain the mountains and the surface streets in the valley all leading to the Los Angeles River. Each of the mountain ranges and hills that surround the San Fernando Valley provide a potential for developing substantial water run-off during heavy localized precipitation events. These channels are dry for the majority of the year. The area surrounding the campus is a developed suburban environment predominantly consisting of residential and commercial land uses. There are industrial facilities and distribution centers located to the south and east of the campus. The Southern Pacific Railroad have tracks located ½ mile south of the campus.

Figure 16-11: Flood Hazard Zones in Greater Los Angeles, CA

---

The CSU Northridge campus is located not in proximity to any significant waterways or flood control systems. The entire CSU Northridge campus sits within a Special Flood Hazard Area (SFHA) Zone X: Area of Minimal Flood Risk designation on the Flood Insurance Rate Map. This minimal flood risk rating extends throughout the western San Fernando Valley with the exception of specific areas near flood control channels. The flood control channels are designated as Zone AE: 1% Annual Chance Flood Hazard and some areas adjacent to flood control channels are designated as Zone X: 0.2% Annual Chance Flood Hazard, and critical services in proximity to the campus are found outside of designated flood risks.

Extent of the Hazard

The CSU Northridge campus is entirely located in a designated Zone X: Area of Minimal Flood Hazard. The access routes into and out of the campus servicing locations in all directions are also found in areas primarily designated as Zone X: Area of Minimal Flood Hazard. Based on the location of the campus and access routes entirely in Zone X and no history of flooding, the planning committee ranks the extent of the hazard as **Low**.
In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 16-22: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised map in place of Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, BFEs derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
<tr>
<td>Zone AH</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.</td>
</tr>
</tbody>
</table>
### Zone AO

1%

Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.

### Zone X (shaded)

0.2%

Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.

### Zone X (unshaded)

**Undetermined**

Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.

### History of the Hazard

Flooding in Northridge and the broader Los Angeles County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the CSU Northridge campus. On campus, occasional flooding is limited to small, isolated pockets of ponding in low lying areas. No records of flooding are reported for the campus.

60 2019 County of Los Angeles All-Hazard Mitigation Plan, 2019
### Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source.

Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Threat or damage to on campus Associated Students Children’s Center
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Inability for campus operations to resume
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

Individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

Los Angeles County is determined have considerable portions of the county to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common in the Los Angeles area with winter storms that are saturated with subtropical moisture. Although there are specific buildings on and areas of the CSUN campus that have a greater risk for isolated flooding, the area surrounding the CSU Northridge campus does not generally promote conditions for flood waters to accumulate. The CSU Northridge campus is located within a Zone X Special Flood Hazard Area (Area of Minimal Flood Hazard) and not in close proximity to areas with greater flood risk. However, there is a historic record of isolated urban or street flood events provides a demonstration of potential flood activity.

The probability of future occurrence for flooding is Unlikely.

Vulnerability to the Hazard

The CSU Northridge campus is subject to the effects of limited and isolated flooding or ponding resulting primarily from excessive precipitation and isolated strong
storms. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of Northridge in low lying areas due to overflow or damage to flood control systems. The channels and extending irrigation systems that surround the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the CSU Northridge campus will vary depending on when the flood was to occur and the location of any people and/or assets in low lying areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community in low lying areas may become trapped on campus depending on the level of flooding occurring on surface streets. However, in very rare, region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

CSU Northridge is in proximity to a variety of industrial and commercial facilities in the surrounding communities. When these facilities are inundated with flood water, the potential for chemical release exists presenting possible exposures to individuals from the campus community. These facilities additionally line many of the primary access routes in and out of the campus. Access routes into and out of the campus may be inundated creating human vulnerabilities in access to medical care, ability to gain access to critical services, access to necessary supplies, and ability to evacuate. The human vulnerabilities would also include the dangers of large volumes of moving or standing water, electrical shock in high water events, and biological contaminants from backed up sewers, mold infestation, and other vectors.

During low probability, severe flood events, some campus buildings and infrastructure would be vulnerable to large-scale flooding if it reaches the university. Campus utilities and communication capabilities in any low lying areas might be impacted by flood waters rendering them disabled. A rare flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls in any low lying areas may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. In such areas, flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of building.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to
support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $550,272,157. However, it is unlikely for flood to cause destructive losses to the entire campus.

**Table 16-24: Special Flood Hazard Area (SFHA) Estimated Losses**

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. In addition to the vulnerabilities posed by localized floods, the proximity to the Aliso Canyon Wash and Los Angeles River further presents a minimal hazard facing the campus.

The potential for flooding generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for rare, widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.
**Hazardous Materials**

**Description of the Hazard**

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

---

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness

**Natural-Technological Incidents (Natechs)**: During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. Please refer to Annex ? for the map identifying the types and locations of hazardous materials and infrastructure on or near the CSU – Northridge campus. The planning committee indicates that chemicals are located in science labs on campus, some of which have radiological properties. Also, the committee indicates that some chemicals may be present but unaccounted for, resulting from an incomplete paper trail for chemicals entering campus. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city of Northridge and county of Los Angeles, and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

---

However, for the CSU – Northridge planning committee, although no events have taken place on campus, lack of procedural oversight and security/management of chemicals inventory and access increases the extent of the hazard risk greatly. In addition, an extensive and dense array of gas pipelines, rail lines, chemical and hazardous waste sites are located close to the campus. Based on these factors, it is prudent to rank the extent of the hazard for the CSU – Northridge campus as Moderate to High, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

According to the campus planning committee, as a result of the 1994 Northridge Earthquake, CSU - Northridge laboratories and chemical storage rooms experienced multiple chemical spills which produced a significant response from students, faculty, staff, and first responders including building evacuation. No events have taken place since that time.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural 66 US Geological Survey. *The Loma Prieta, California, Earthquake of October 17, 1989 – Fire, Police, Transportation and hazardous Materials* Retrieved 04.19.2021 from: https://pubs.usgs.gov/pp/pp1553/pp1553c/

unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – Northridge campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. 68 Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

Potential Impacts of the Hazard (Natechs)

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (as exemplified by the event at CSU – Northridge) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the

environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

**Probability of Future Occurrence of the Hazard**

The probability of occurrence for a hazmat event on the CSU – Northridge campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Moderate to High - the campus has experienced chemical spill events and is in need of improvements in chemical labs access and chemical tracking and management protocols on campus. As such, the risk of occurrence is multiplied. In addition, nearby hazardous materials and infrastructure further increase vulnerability and probability of a campus-related event. Moreover, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

**Vulnerability to the Hazard**

Hazardous materials pose a large risk to the CSU – Northridge campus. As identified by the campus planning committee and on the hazmat map (see section X), the following vulnerabilities are present on campus: chemicals are present in many science and research labs, and other storage facilities. However, tracking and oversight of chemicals and related protocols need improvement which increases vulnerabilities. In addition, gas pipelines and hazardous waste sites are extremely close to the campus footprint. Gases and chemicals or hazardous waste, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Northridge leadership
maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Northridge) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Los Angeles County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Northridge campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.
Identified Data Limitations

The CSU – Northridge planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

Landslide

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may

---

impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 16-3. Based on the Figure (below), the CSU Northridge campus is located in an area with a low degree of susceptibility to landslide.
Figure 16-12: Deep-seated Landslide Susceptibility Surrounding CSU Northridge. 

Extent of the Hazard

In Northridge, landslides are more likely to occur in the steep slopes surrounding the city. The San Gabriel mountains, both steep and erosive, contain steeply walled canyons above areas with high population density. When heavy rain occurs, there is significant potential for floods and landslides throughout the County, and indirect impacts of landslides may cover a larger geographical extent. Based on the campus’ location removed from landslide susceptibility zones, the planning committee ranks the extent of the hazard as **Low**.

History of the Hazard

FEMA has declared thirteen major disasters involving landslides, mudslides, debris flows, or mud flows in Los Angeles County since 1978. NOAA has recorded five debris flow events in the County since 2004, most of which occurred in the areas directly

---

surrounding metropolitan Los Angeles. The 2018 Southern California Mudflows damaged 40 to 45 homes in Sun Valley and caused a vehicle to strike a natural gas pipeline, which began to leak. The campus has no history of landslide occurrences.

Potential Impacts of the Hazard

CSU Northridge may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are also often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. According to the NCEI Storm Events Database, Los Angeles has been impacted by earthquakes, wildland fires, and severe storms at least every other year since 1960. Given the historic frequency of these contributary sources to landslides and of recorded landslides themselves, the probability of future occurrence for the City of Los Angeles is high. However, CSU Northridge campus itself is located in an area with a low degree of susceptibility to landslide, and there is no reported history of landslides on campus. As a result, the probability of a landslide occurring on campus on an annual basis is rated as **Unlikely**.

Vulnerability to the Hazard

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. That said, the campus’ vulnerability is limited to secondary effects of a landslide such as power outage or transportation disruption.
Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Northridge.

Vulnerability Assessment Conclusions

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the CSU Northridge campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.

Power Outage

Description of the Hazard

Northridge is a neighborhood of the City of Los Angeles located in the San Fernando Valley. It is also the home of CSU Northridge (CSUN).

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly populated areas like Northridge (and Los Angeles) without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the CSUN campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of CSUN student residents in on-campus housing would also be affected by a power outage on campus and in the area.
Additionally, a severe outage in Northridge and/or in the City of Los Angeles would also directly affect the campus and the community.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions are:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, as a hazard, it has the potential to occur and affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:
Stage 1 - reserve margin falls below 7 percent.
Stage 2 - reserve margin falls below 5 percent.
Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached.

A power outage could affect the entire area of the campus, including the SJSU athletic fields, classrooms resident halls, administrative offices, virtual, telephonic and radio communications, leading to loss of lighting in campus parking structures, and creating a cascading hazard for commuters as they depart from or arrive to campus in the evening. Additionally, the university is located within proximity of highly utilized thoroughfares for the transportation of goods to throughout California, within one of the busiest areas of the Silicon Valley.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. However, given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard

CSU Northridge has experienced power outages for various reasons. The following are examples of power outage events experienced over the last 10 years:

- May 15, 2015; CSU Northridge experienced a power outage. Commencement ceremonies scheduled for that evening took place as scheduled at 6pm.
- April 15, 2016; A windstorm early in the morning caused power outages throughout the area, including CSU Northridge. The campus remained open and continued to operate. The power outage affected multiple buildings on campus including Student Housing Complex, Chisholm Hall, Monterey Hall, Matador Bookstore, Klotz Student Health Center, Valley Performing Arts Center, Cypress Hall, Nordhoff Hall, Manzanita Hall, Santa Susana Hall, parking lots/structures B1, B2, B3, G3, as well as KCSN. Students in affected areas were able to report to class for further instruction, and employees report to their department.
- October 6, 2016; A power outage affected Sierra Hall, Redwood Hall, Manzanita Hall, and the Oviatt library. This power outage affected both the campus and the surrounding Northridge community.

Potential Impacts of the Hazard

Instructors, campus residents, staff, and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on
electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

**Climate Change and Energy Shortage**

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City of Los Angeles and Los Angeles County experience such outages. As such, the probability ranking for the Los Angeles area is **Likely**. Since the CSU Northridge campus has also recorded power outage events, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to...
people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

Estimate of Potential Losses

The data provided by CSU Northridge does not report any value for potential losses due to power outage.

Vulnerability Assessment Conclusions

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at CSU Northridge. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

CSU Northridge did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
Volcano (Associated Air Quality)

Description of the Hazard
The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”72

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.73

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard
There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU Bakersfield or Kern County is within a volcano hazard zone.

Extent of the Hazard
Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While CSU Northridge does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low. History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California.11 The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.12

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Northridge is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Northridge.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Northridge, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses
Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

CSU Northridge is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain.\(^74\) These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

\(^74\) State of California Hazard Mitigation Plan, September 2018
California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. CSU Northridge and the San Fernando Valley are located in a densely populated area of north Los Angeles. This area near the university is
dominated by urban and suburban communities with limited direct exposures to wildland fire. CSU Northridge has extensive residential neighborhoods to the north, east, and south of campus. The western side of the campus is largely a commercial area. Industrial land uses are located to the southwest of the campus.

The CSU Northridge campus is located in the center of the San Fernando Valley within the City of Los Angeles. The campus is 4 miles south of the Santa Susana Mountains, the closest area designated as having a high fire hazard where there are large areas of hillsides with moderate to heavy vegetative fuels. The campus is not located next to areas with a fire hazard potential making direct impacts by fire on the campus unlikely.

However, the CSU Northridge campus is surrounded by mountains and extensive areas of fire hazards further away. Surrounding the Los Angeles Basin are large mountain ranges including the San Gabriel, San Bernardino, and Santa Ana Mountains. These mountain ranges host three national forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the basin in the right wind conditions. The geography of the Los Angeles Basin and San Gabriel, San Fernando, and San Bernardino valleys creates a topography that captures air pollutants including smoke within surrounding mountains and the development of inversion layers. The CSU Northridge campus is located in a region in which wildfire smoke can saturate the air around the campus.
Extent of the Hazard

The area immediately surrounding the CSU Northridge campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones, and the campus does not have a history of wildfire activity occurring within proximity to the campus. However, the San Fernando Valley is surrounded by mountain ranges containing forests with an extensive history of large wildfire development and smoke generation. As a result, the planning committee ranks the extent of the wildfire hazard for the SJSU campus as Moderate.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions. The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 5-25: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>(L)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>Danger (M)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>(H)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

<table>
<thead>
<tr>
<th>CLASS 4: Very High Danger (VH)</th>
<th>Fires start very easily and spread at a very fast rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Orange</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CLASS 5: Extreme (E)</th>
<th>Fire situation is explosive and can result in extensive property damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Red</td>
<td>Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</td>
</tr>
</tbody>
</table>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Los Angeles County also has a long history of wildfire activity primarily in the foothills and mountains of the San Gabriel and Santa Monica Mountains. Wildfires occurring in Los Angeles County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damages.

The area immediately surrounding the CSU Northridge campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and/particulates into the air. The Northridge campus has experienced multiple days of poor air quality due to fires burning in Los Angeles, Orange, Riverside, and San Bernardino Counties. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Los Angeles County. CSU Northridge personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

**Potential Impacts of the Hazard**

The location of the CSU Northridge campus surrounded by areas of urban development removed from areas with a fire hazard places a minimal direct threat from wildfire to the campus. The potential impacts to wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Threat or damage to on campus child care facilities
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage or reduction of capacity to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects

---

79 2019 Los Angeles County All-Hazards Mitigation Plan, 2019
Similar health impacts to pets

- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Los Angeles County including the campus may be damaged resulting in power outages. Fire-related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the minimal wildfire threat potential in the area surrounding the CSU Northridge campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered Unlikely.

Based on the wildfire threat potential in the area surrounding Southern California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered Possible.

Vulnerability to the Hazard

The CSU Northridge campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban/suburban area of the San Fernando Valley. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of the urban areas of Los Angeles. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than
older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

Some areas of particular vulnerability on the campus includes:

- Students and staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC or do not have HVAC will cause limitations in filtering of air during smoke filled days
- Power outages or brownouts during days with high levels of smoke will limit shelter in place options during heat events in summer.

The greater concerns regarding vulnerabilities to wildfire on CSU Northridge are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Los Angeles Basin even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Northridge students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU Northridge campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary
costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $550,272,157. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher. However, the location of the campus in an urban/suburban setting removed from hazard prone areas makes wildfire related damages unlikely.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Los Angeles County; however, wildfire incidents do not pose a direct risk to the CSU Northridge campus. The location of the CSU Northridge campus surrounded by densely developed residential, commercial, and industrial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The students, faculty, and staff of CSU Northridge who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the campus. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local...
economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.

Additionally, the topography of Southern California surrounded by mountains allows for smoke filled air to linger in the valleys of the Los Angeles Basin with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains generating tremendous quantities of smoke present tremendous health related vulnerabilities to members of the campus community. The campus community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**16.4 Social Resilience Assessment**

**Overview**

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Northridge campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.
This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning?</td>
<td>Deaf students</td>
</tr>
<tr>
<td>Which population groups are most difficult to reach in an event?</td>
<td>• Deaf students</td>
</tr>
<tr>
<td></td>
<td>• Commuter students</td>
</tr>
<tr>

<td>• Deaf students</td>
</tr>
<tr>
<td></td>
<td>• Students in &quot;their&quot; housing, under- resourced</td>
</tr>
</tbody>
</table>
Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as *Very High, High, Medium, Low*
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as *Yes, No, In Progress, NA*

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- pride self on being open and aware of the many facets of the culture; 2nd most diverse population group for students.
- DAFN is baked into the EOP; noted that the City of Los Angeles went through a lawsuit
- International students in the extended learning; community approach is working with their EOP that is an annex to the campus EOP
- Campus social media teams monitors Nextdoor

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal
experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

</tbody>
</table>
**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods. Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states. Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifi cally realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing

_____________________

---

market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.\(^{82}\)

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

---

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.”

_Hazardous Materials_

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the

---

time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease. Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.

**Landslides**

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied buildings makes it a function of structural vulnerability and therefore, indirect. The degree of vulnerability to landslides by an individual considered at high risk, or even the general populations, also depends on human behavior, including many of the traditional social factors that are difficult to measure such as situational awareness, prior knowledge of hazards, and decision-making capabilities.

Landslides can result in primary lifeline failures through the loss of roads or power and communication lines. Transportation routes are often expensive to clean up, and

84 [https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/](https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/)

prolonged obstruction can disrupt the movement of people and goods. Risk from landslides relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. 87 Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old. 88

---

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such as heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.  

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

17.1 University Profile

University History

In 1938, California Polytechnic School, founded as a vocational high school in 1901, acquired the Voorhis School for Boys, a private vocational school founded in 1928, following economic pressures from the Great Depression. The two units operated as one institution, by that time a two-year college. During WWII, most of the student body was called to active military duty, forcing the campus to close in 1943. When it reopened in 1956, the Voorhis unit was moved to a former horse ranch in the neighboring city of Pomona and renamed Cal Poly Kellogg-Voorhis Unit. Five years later, both campuses were added to the California State College system and separated into two independent universities in 1966. Cal Poly Kellogg-Voorhis finally adopted its present-date name California State Polytechnic University, Pomona (Cal Poly Pomona) in 1972.

Today, Cal Poly Pomona includes eight colleges and is classed as a Master's College and University by the Carnegie Institute. It is designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

Management of the university is split between five divisions: Academic Affairs, Administrative Affairs, Student Affairs, Information Technology, and University Advancement.

The Academic Senate is the primary consultative body for educational and other university policies, academic personnel policies, selection of administrative officials, and university administrative regulations and practices. Each of the standing committees, of which there are six, write reports with recommendations, which are then voted on by the senate. If approved, the recommendation is sent to the President, who has the power to accept, modify, or reject.

University Mission

“We cultivate success through a diverse culture of experiential learning, discovery, and innovation.”
In pursuit of this mission, the university has outlined five strategic initiatives. Central to these is providing quality academic programs that promote creativity, enhance student success, and prepare students for the workplace and for civic engagement. Furthermore, Cal Poly Pomona seeks to invest in personnel and strengthen their economic vitality and impact.

**University Location**

Cal Poly Pomona is located in Pomona, a suburban city that is in the eastern portion of the Los Angeles metropolitan area. Its 1,725-acre campus is the second largest in the California State University system and includes a 53-acre ranch in Santa Paula, 25-acre campus at Spadra Ranch, and the Neutra VCL Studio and Residences in Silver Lake. The university is currently negotiating the transfer of a 302-acre development center from the State of California.

The university is proximal to the San Jose Fault, believed to run through campus.

**University Population**

Cal Poly Pomona typically enrolls between 20,000-25,000 students per semester. In fall 2020, the 27,909-student population was overwhelmingly made up of undergraduate degree seekers with an average age of 23. Hispanic students made up 49% of all students, with Asian students making up the second most populous group at 21%. Just over half of all students are first generation.

In addition to the student population, the University is home to approximately 1,500 faculty and staff.

**17.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment**

**Requirement §201.6(c)(2):** The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

**Requirement §201.6(c)(2)(i):** [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

**Requirement §201.6(c)(2)(ii):** [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

**Requirement §201.6(c)(2)(ii):** [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.
Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

17.3 Hazard Identification and Risk Assessment

Overview of Cal Poly Pomona History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-
To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 17-1 (following).

Table 17-1: Hazard Identification Determinations

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:
• Highly Likely- 76%-100% that the hazard would occur annually.
• Likely- 50%-75% that the hazard would occur annually.
• Possible- 11%-49% that the hazard would occur each annually.
• Unlikely- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 17-2 below.)

**Descriptions of Identified Communicable Disease Hazards at Cal Poly Pomona**

Cal Poly Pomona has identified two (2) communicable disease hazards that have had the greatest impact on campus – COVID-19 and Influenza (Swine Flu - H1N1). The following are brief descriptions of the communicable disease hazards at Cal Poly Pomona.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death. 5

**Influenza (Including sub-type H1N1/Swine Flu)**

Influenza is a viral infection that attacks the respiratory system (i.e., nose, throat, and lungs). Influenza viruses travel through the air in droplets when someone with the infection coughs, sneezes or talks. Influenza is transmitted either by inhaling virus-laden droplets directly, or by coming into physical contact with an object (e.g., telephone or computer keyboard) and then transferring the virus to the eyes, nose or mouth. People with the virus are likely contagious from about a day before symptoms appear until about five days after symptoms begin.

Common signs and symptoms of the flu include: fever, aching muscles, hills and sweats, headache, dry and persistent cough, shortness of breath, tiredness and weakness, runny or stuffy nose, sore throat, and eye pain. (Vomiting and diarrhea are also influenza signs and symptoms, but these are more common in children than in adults.)

Influenza viruses are constantly changing, with new strains appearing regularly. As a result, antibodies against influenza viruses that have been encountered in the past may

not offer protection from new influenza strains, as the new strains can be very different viruses from previous strains. 6

**H1N1 Flu (Swine Flu)**

The H1N1 flu, commonly known as swine flu, is a type of influenza A virus and is one of several flu viruses strains that can cause the seasonal flu. It is primarily caused by the H1N1 strain of the flu (influenza) virus. Symptoms of the H1N1 flu are the same as those of the seasonal flu.

The H1N1 virus is a combination of viruses from pigs, birds and humans that causes disease in humans. The virus enters your body when you inhale contaminated droplets or transfer live virus from a contaminated surface to your eyes, nose or mouth. It then infects the cells that line your nose, throat and lungs. 7

**Location of the Hazard**

Communicable diseases have the potential to affect the entire Cal Poly Pomona planning area equally. As a result, the communicable disease hazard can be found at Cal Poly Pomona main campus located in Pomona, CA (Los Angeles). The communicable disease hazard can also be found at three (3) off-campus research facilities that Cal Poly Pomona operates: (1) Pine Tree Ranch, a 53-acre citrus and avocado ranch in Santa Paula, CA (Ventura Country); (2) Westwind Ranch, a 1,000-acre farm in the city of Chino, CA (San Bernardino County); and (3) Spadra Ranch, a 125-acre site located approximately one mile from the main campus (Los Angeles County). Furthermore, the communicable disease hazard can be found at the Cal-Poly-Pomona-owned Neutra VCL Studio and Residences in Los Angeles, CA (Los Angeles County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) Cal Poly Pomona are at risk of exposure to the communicable disease hazard.8

**CSU Student Housing Locations and Populations**

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For Cal

---

Poly Pomona, approximately 9% of its 27,914 enrolled students (or 2,512 students) reside in student housing. 9-10

**Extent of the Hazard**

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 17-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

The Extent of Cal Poly Pomona Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Influenza at Cal Poly Pomona. Influenza – H1N1 would be classified at either the BSL-2 or BSL-3 containment level, depending on the strain.12

The Extent of Cal Poly Pomona COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3. 13

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 297 cases of COVID-19 at Cal Poly Pomona. Most communicable disease data are maintained by at the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-

19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 17-5, 17-6, 17-7, and 17-8 show campus-level and County-level COVID-19 Case data for Cal Poly Pomona. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

*On-Campus Case Definition*: When a student, faculty or staff member reports a positive lab test for COVID-19 to Cal Poly Pomona, and the individual has been on campus during the contagious period.

** Off-Campus Case Definition**: When a student, faculty or staff member reports a positive lab test for COVID-19 to Cal Poly Pomona, but the individual has NOT been on campus during the contagious period. This reporting includes members of the campus community learning and working remotely, and it also follows Los Angeles County Department of Public Health’s definition for “Institutes of Higher Education” settings\(^{15}\).

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system (including the Cal Poly Pomona campus). The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of Cal Poly Pomona students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including Cal Poly Pomona) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.). 19

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

---

### Table 17-8: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 17-10 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

---

Table 17-9: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>
These bacteria and viruses cause severe to fatal disease in humans, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

Probability of Future Occurrence of the Hazard

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.

Table 17-11 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:
### Table 17-10: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence. Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at CSU campuses. CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, CPSU – Pomona campus had 21,242 students and additional faculty and staff.) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic at Cal Poly Pomona.

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including Cal Poly Pomona) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities.

22 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

23 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx

emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 17-2 below for the economic impact to the Cal Poly Pomona campus.) Several CSU campuses saw refund losses surpass $10 million. (See Figure 17-2.)

Figure 17-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs

---

**Mitigative Relief from Federal Assistance**

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 17-13.) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

</table>
Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CPSU – Pomona had 21,242 students and additional faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity. At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. *If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time.* This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 17-14 below for the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system (including Cal Poly Pomona). In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.
There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

**Identified Data Limitations**

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).
**Drought**

**Description of the Hazard**

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for Cal Poly Pomona) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified in Los Angeles County and the city of Pomona where Cal Poly Pomona is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years. 31

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout Los Angeles County which surrounds the planning area and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies.

In addition, although drought affects the entire CSU system-wide planning area, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. CPSU Pomona maintains access to 4 water wells and reclaimed water for irrigation, and the extent of drought on campus is low.

In addition, land subsidence has occurred statewide and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. These effects have not occurred on campus, but remain issues of concern over the long term.

For Cal Poly Pomona, the extent of the hazard is Low (corresponding to D0-D1 on the extent scale below). However, the campus planning committee recognizes that the potential for more severe conditions exists over the long term and is tied to regional water resource vulnerabilities.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

Table 5-14: Impacts of Drought Levels as Determined by US Drought Monitor

<table>
<thead>
<tr>
<th>Category</th>
<th>Impact</th>
</tr>
</thead>
</table>
| D0       | Soil is dry; irrigation delivery begins early  
Dryland crop germination is stunted  
Active fire season begins  
Winter resort visitation is low; snowpack is minimal |
| D1       | Dryland pasture growth is stunted; producers give supplemental feed to cattle  
Landscaping and gardens need irrigation earlier; wildlife patterns begin to change  
Stock ponds and creeks are lower than usual  
Grazing land is inadequate  
Producers increase water efficiency methods and drought-resistant crops  
Fire season is longer, with high burn intensity, dry fuels, and large fire spatial extent; more fire crews are on staff |
| D2       | Wine country tourism increases; lake- and river-based tourism declines; boat ramps close  
Trees are stressed; plants increase reproductive mechanisms; wildlife diseases increase  
Water temperature increases; programs to divert water to protect fish begin  
River flows decrease; reservoir levels are low and banks are exposed |
| D3       | Livestock need expensive supplemental feed, cattle and horses are sold; little pasture remains, producers find it difficult to maintain organic meat requirements  
Fruit trees bud early; producers begin irrigating in the winter |

</table>
History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous. According to the US Drought Monitor, Time Series Los Angeles County (which encompasses the city of Pomona and the campus) has experienced five periods of drought covering 14 years between 2000 – 2021, including a severe drought from 2012 – 2019.

Figure 17-3: Periods of Drought in Los Angeles County, CA, 2001 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.

34 NCEI. Storm Events. Retrieved 5.2.2021 from: https://www.ncdc.noaa.gov/stormevents

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions has been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 17-4: Periods of Drought in State of California, 2001 – 2021

![California Percent Area](image)

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on Los Angeles County which surrounds the Cal Poly Pomona campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck.” Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has

contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent. 37

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that although historic drought impacts have not been reported for the planning area, potential impacts are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the Cal Poly Pomona campus planning area is a potential reduction in water availability for the municipal area tied to the campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of Cal Poly Pomona to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of any agricultural research crops and/or field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. 38 However, the wildfire hazard is analyzed separately in this plan. (See wildfire section later in this document).

In reviewing the occurrences of drought for Los Angeles County (surrounding the Cal Poly Pomona), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to Cal Poly Pomona, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is

---

currently available for tree mortality on campus; however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct — in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area. 39

At present, drought related damage to campus buildings and infrastructure at Cal Poly Pomona has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for Cal Poly Pomona is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including Cal Poly Pomona. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Table 17-15: Summary of Drought Impacts on Water Resources40

</table>

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that Cal Poly Pomona lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area. 41

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the Cal Poly Pomona campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the Cal Poly Pomona planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2 million acre-feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

**Vulnerability of Populations**

Drought vulnerabilities for California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerability measures apply to the students, faculty and staff of the Cal Poly Pomona campus.

**Property Vulnerability**

Drought vulnerabilities include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and

land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerability measures apply to the properties of the Cal Poly Pomona campus.

**Natural Environment Vulnerability**

Drought vulnerabilities for the natural environment on campus are primarily flora and landscaping. Statewide, vulnerabilities are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping. 43

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for Cal Poly Pomona’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of Pomona and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Conclusions**

43 USGS. Forest and Rangeland Ecosystem Science Center. Retrieved 5.4.2021 from: https://www.usgs.gov/centers/fresc
The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

Identified Data Limitations

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.

*Earthquake*

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act
as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. Cal Poly Pomona is located in the San Gabriel Valley of eastern Los Angeles County. In general, fault systems surround and traverse through Los Angeles and Orange Counties including the area of Cal Poly Pomona. Throughout the basin the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 20-25 miles northeast of the Cal Poly Pomona campus. In addition to the San Andreas Fault, Los Angeles County is home to or near additional fault systems with the potential to generate strong ground shaking. The Elysian Park Fault extends across the southern boundary of the campus in an east to west direction. The Hollywood-Raymond Fault is another east to west fault 3 ½ miles north of the campus connecting Arcadia and Beverly Hills. The Puente Hills Fault extends from the southern base of the Puente Hills to
downtown Los Angeles approximately 5 miles southwest of the campus. The Newport-Inglewood Fault traverses south to north paralleling the Orange County coastline extending 12 miles southwest of the Cal Poly Pomona campus. The Verdugo Fault extends from South Pasadena northwest to San Fernando 5 miles to the north of the campus. There are numerous additional faults in the area on all sides of the campus.

Figure 17-5: Fault Lines in Proximity to Cal Poly Pomona

The Cal Poly Pomona campus is located within areas designated to be liquefaction zones. All campus facilities are located within the liquefaction zone or areas where liquefaction zones overlap with areas prone to landslides. Additionally, substantial areas of the community surrounding the campus reside within the liquefaction zones including access routes into and out of the campus. This includes Interstate 10, State Route 57, State Route 60, Valley Blvd., and the Union Pacific Railroad. The liquefaction zone generally follows the path of the San Jose and Diamond Bar Creeks.
Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude and intensity. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The

Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:
<table>
<thead>
<tr>
<th>Intensity</th>
<th>Shaking</th>
<th>Description / Damage</th>

</tbody>
</table>

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increase in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 17-7: Earthquake Magnitude and Equivalent Energy Release

The Cal Poly Pomona campus is located within areas designated to be liquefaction zones. All campus facilities are located within the liquefaction zone or areas where liquefaction zones overlap with areas prone to landslides. Fourteen fault systems traverse the areas surrounding the campus. In addition, numerous severe and even catastrophic events have taken place in the region. Based on these factors, the planning committee ranks the extent of the hazard for the campus as **High.**

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Los Angeles County also has a long history of earthquake activity. The entire area of the Los Angeles Basin is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The January 9, 1994 Northridge Earthquake became the costliest seismic event in California history. The earthquake caused extensive damage to structures, the transportation infrastructure, utility systems, water storage, communications, and critical facilities. This level of damage due to the fault that ruptured was directly underneath a densely populated urban area. The Northridge Earthquake was found to raise the nearby mountains by as much as 70 centimeters. The earthquake was provided a federal disaster declaration (DR-1008).

The October 1, 1987 Whittier Narrows Earthquake shook a large part of southern California. The earthquake caused $358 million in damages, especially in the Alhambra, Pasadena, and Whittier areas. The earthquake resulted in extensive infrastructure...
damages, multiple injuries, and 8 fatalities. The earthquake was provided a federal disaster declaration (DR-799).

The February 9, 1971 Magnitude 6.5 San Fernando Earthquake struck the San Fernando Valley in Los Angeles just after 6am. The intense shaking caused the collapse of freeway overpasses, hospitals, and other infrastructure. It damaged thousands of homes and businesses, a reservoir, and critical infrastructure. 65 people were killed and 2,000 more were injured. The shaking was felt for 300 miles including in Las Vegas, Nevada. The earthquake was provided a federal disaster declaration (DR-299).

The March 10, 1933 Long Beach Earthquake registered at a Magnitude 6.4 occurred along the Newport-Inglewood Fault. The earthquake resulted in over $50 million in damages, 500 injuries, and 120 fatalities. Unreinforced masonry structures were the source of most of the casualties. 70 schools were destroyed and 120 were damaged. This earthquake promoted statewide standards in building design and construction for schools and other structures to better withstand seismic events.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils on the campus and surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Pomona area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Pomona could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Pomona could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Los Angeles County region limiting immediate assistance that the campus may normally expect.

Local impacts to the Cal Poly Pomona campus caused by an earthquake could include:

- Damage and secondary fires to industrial buildings to the southeast of campus
- Potential hazardous material releases on and off campus
- Potential liquefaction-based effects to areas of the surrounding neighborhoods to the west
- Potential for liquefaction-based landslides on campus
- Infrastructure damage to freeway system
- Structural damage to bridges
- Damages to rail lines and rail cars ¾ mile to south of campus
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to flood control and drainage systems
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences and apartment complexes
- Community members arriving on campus for refuge from damaged homes
- Potential landslide or damages to Spadra Landfill across street from campus
- Damages or releases from water storage tanks on hill near Kellogg House
- Damaged university communications, computer systems, and networks
- Damage to facilities securing on-campus animals
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue
- Needs for assistance or shared resources from neighboring Mt San Antonio College

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Los Angeles County fault systems surrounding Pomona is included in the following table.
Based on the earthquake shaking potential in the Los Angeles Basin, the proximity to the above listed fault systems, the probability of seismic ground shaking generating damage is considered Possible.

### Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of Cal Poly Pomona places the campus in a suburban community near residential, commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

---

48 2019 County of Los Angeles All-Hazards Mitigation Plan, 2019

The known fault systems generating the threat to Pomona generally surround the city and some cross into the city including near the Cal Poly Pomona campus. The closest being the San Jose Fault extending along the northern edge of the campus. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. A lack of earthquake insurance will cause extreme financial burdens on those affected.

Elements of the vulnerability to a major earthquake on the Cal Poly Pomona campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the city. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus to other locations that are deemed to be safer locations. The Interstate 10 and State Route 57 Interchange is a multi-level interchange residing on an area deemed a liquefaction zone. The potential exists for collapse and a compromise to evacuation, access, and supply routes. Other prime freeway interchanges including the State Routes 57 and 60 interchange and the State Routes 60 and 71 interchanges reside on liquefaction zones.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services,
require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $355,971,530.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater Los Angeles region and the Cal Poly Pomona campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the Cal Poly Pomona campus and community.
In the event that a major earthquake was to strike along the many fault systems surrounding Pomona, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Los Angeles County region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

Vulnerabilities will be seen in the physical infrastructure on the campus and the human population of the campus community. Campus infrastructure is vulnerable to severe shaking particularly in areas where the ground is loose or susceptible to liquefaction. Specifically older buildings, masonry constructed buildings, and other structures susceptible to shaking related damage are the most vulnerable. Communication systems, computer networks, and other electronic systems may be vulnerable when overwhelmed by increased demand during emergencies or by shaking related damages. The people of the campus community are vulnerable to effects of intense shaking in the form of injuries from falling debris, exposure to secondary floods or fires, loss of employment, extreme disaster induced stress, and loss of access to critical services or social contacts.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Erosion**

**Description of the Hazard**

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from
one place to another”. Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable.

Location of the Hazard

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across all those areas of the campus with erosion-prone characteristics. The northern portion of campus is considered to be exposed to erosion hazards. Additional locations may be identified in the future.

Extent of the Hazard

There is no published scale of severity or extent for this geologic hazard. If conditions are favorable, erosion is likely to occur. Though no occurrences have taken place, the northern portion of campus is considered to be exposed to erosion hazards, and campus leadership monitors such conditions. As such, the planning committee ranks the extent of the hazard as **Low to Moderate**.

History of the Hazard

There are no recorded incidents of erosion on the Cal Poly Pomona campus, although the northern portion of campus is considered exposed to erosion hazards.

Potential Impacts of the Hazard

Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

In agricultural areas, the erosion of soil degrades the quality of the soil, which can lead to reduced crop yields. At the Don B. Huntley College of Agriculture, soil erosion can create significant concerns for agriculture and research. Eroded test plots can negatively impact experiments and tests, resulting in a loss of knowledge and data.

**Probability of Future Occurrence of the Hazard**

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, the probability of at least a limited degree of erosion taking place somewhere on the campus is **high** over the long term.

**Vulnerability to the Hazard**

Topography, soil structure, land use, and precipitation are all factors of erosion. Cal Poly Pomona infrastructure, buildings, and agriculture located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. In the wider Pomona community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks. Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

**Vulnerability Assessment Conclusions**

While the ability to predict future erosion on the Cal Poly Pomona campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

---

**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Description of the Hazard (Extreme Heat)**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.52

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.53 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.54

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.55 In extreme cases, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.56

**Location of the Hazard**

Extreme heat events are a non-spatial hazard, and may occur at the Cal Poly Pomona campus.

**Extent of the Hazard**

Extreme heat has a wide range of extent and severity markers and characteristics. In the City of Pomona, monthly average maximum temperatures in June through October range

54 Ibid.

approximately from the low 80s to the low 90s. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded in the City of Pomona was 113°F on July 22, 2006. Given 2 additional extreme heat events resulting in the deaths of eight people and extended power outages, the planning committee ranks the extent of the hazard as **Moderate to High**.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104°F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105°F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach those criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 17-8 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

As the heat index rises, so does the potential danger to people and animals. Table 17- (following) shows the health hazards associated with extreme heat.

**Table 17-21: Health Risks Associated with Heat Index**

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, along with the 113 degree event in Pomona in 2006, there have been five excessive heat events in Los Angeles County (home to Cal Poly Pomona) since 1950, but all taking place from 2007 to the present. These events were consolidated within two periods in 2007 and 2008.

**August 30, 2007; September 1, 2007; September 3, 2007:** A combination of high temperatures and high humidity produced an extreme heat event across Los Angeles County and much of Southern California. Heat index values ranged from 105° to 112° F. *Eight deaths were attributable to this excessive heat event.*

**June 20, 2008; June 21, 2008:** Afternoon high temperatures during this extreme heat event climbed as high as 114° F. The heat resulted in several power outages due to excessive electrical use.

Potential Impacts of the Hazard

Cal Poly Pomona may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard
There have been no extreme heat events in the City of Pomona or Los Angeles County in over a decade. Therefore, using the scale provided, it is only **Possible** that the hazard will occur annually. It is also important to note that Los Angeles County considers extreme heat as a hazard, but only as one small part of a larger discussion regarding the effects of climate change.59

**Vulnerability to the Hazard**

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.60 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Cal Poly Pomona is aware of the potential for extreme heat events. All buildings are air-conditioned and during excessive heat events, the campus will have an ambulance or mobile medical team on alert for students, faculty, or staff who may experience heat-related illness.

The risk of power shut-offs affecting air conditioning is not a concern for the campus. Cal Poly Pomona is identified by Southern California Edison as a university and is therefore last on the utility’s list to be affected during planned black-outs or brown-outs.

Therefore, while this is a hazard that the campus may occasionally experience, the campus has measures in place to handle the risks and vulnerabilities.

59 2019 County of Los Angeles All-Hazards Mitigation Plan. 4.1 Climate Change. Print. Retrieved 01.27.21 from: https://lacounty.gov/emergency/county-of-los-angeles-all-hazards-mitigation-plan/

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the Cal Poly Pomona campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three degrees on average over the last century, with less rainfall. This may lead to stronger heat events, drought, and an increased risk of wildfires.61

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

**Hazardous Materials**

**Description of the Hazard**

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”

Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health.

Information provided by California Division of Safety and Health includes guidelines related to:

• **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)

• **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs)**: During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. Please refer to Annex ? for the map identifying the types and locations of hazardous materials and infrastructure on or near the Cal Poly Pomona campus. The planning committee indicates that radioactive materials are located in a building leased to the American Red Cross and chemicals are located in the chemistry lab on campus. At larger scales (beyond the campus planning area) hazardous materials are located throughout the city of Pomona and Los Angeles County, and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

---

However, for the Cal Poly Pomona planning committee, although no hazmat events have taken place on campus, hazardous materials include chemicals in the science building, and radioactive material in a leased building on campus, as well as a rail line running through campus. Based on these factors along with the types and levels of hazardous materials in the larger community, it is prudent to rank the extent of the hazard for the Cal Poly Pomona campus as Moderate to High, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. 67 That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located. 68

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

No hazmat incidents have taken place on the Cal Poly Pomona campus.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result

in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the Cal Poly Pomona campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak69, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health.70 Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

Potential Impacts of the Hazard (Natechs)

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including Cal Poly Pomona) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, ______

manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the Cal Poly Pomona campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low because the Cal Poly Pomona campus has not experienced hazmat events. That said, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the Cal Poly Pomona campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: chemicals are present in the science lab, radioactive material is located in the building leased to the ARC, a rail line runs near the north side of campus and a gas pipeline near the south side. Gases, chemicals or radioactive materials, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the Cal Poly Pomona leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based
upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including Cal Poly Pomona) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Los Angeles County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the Cal Poly Pomona campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The Cal Poly Pomona planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
Landslide

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak

material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 17-9. Based on the Figure below, the campus is surrounded by high susceptibility landslide zones.

Figure 17-9: Deep-seated Landslide Susceptibility Surrounding Cal Poly Pomona

---

**Extent of the Hazard**

The San Gabriel mountains, both steep and erosive, contain steeply walled canyons above areas with high population density. When heavy rain occurs, there is significant potential for floods and landslides throughout the County. Most of the City of Pomona is

---

located on flat topography, however the hillsides in the western portion are considered susceptible to landslides. The indirect impacts of landslides in the region may cover a larger geographical extent than that of direct impacts. Based on the campus’ location surrounded by high susceptibility zones, and the extensive history of occurrence in Pomona, the planning committee ranks the extent of the hazard as Moderate to High.

History of the Hazard

FEMA has declared thirteen major disasters involving landslides, mudslides, debris flows, or mud flows in Los Angeles County since 1978. NOAA has recorded five debris flow events in the County since 2004, most of which occurred in the areas directly surrounding metropolitan Los Angeles. The 2018 Southern California Mudflows damaged 40 to 45 homes in Sun Valley and caused a vehicle to strike a natural gas pipeline, which began to leak.

The City of Pomona experienced a small landslide in 2006 that destroyed 4 homes and caused 6 million dollars in damage. In March 2003, a landslide occurred in Ganesha park, causing a temporary closure of Paige Drive. A history of landslides on the campus has not been reported.

Potential Impacts of the Hazard

Cal Poly Pomona may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are also often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. According to the NCEI Storm Events Database, the City of Los Angeles has been impacted by

__________________________

earthquakes, wildland fires, and severe storms at least every other year since 1960. Given the historic frequency of these contributary sources to landslides and of recorded landslides themselves, the probability of future occurrence is high. Based on these factors, the probability of annual future occurrence on the campus is Possible.

Vulnerability to the Hazard

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. Based on the campus’ location, from the mapping it appears that the campus exhibits all vulnerabilities (above) to some degree. The Cal Poly Pomona campus leadership may consider a broader assessment of asset vulnerability in the future.

Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to Cal Poly Pomona.

Vulnerability Assessment Conclusions

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the Cal Poly Pomona campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.
Power Outage

Description of the Hazard

Pomona, California is a city located in between the Inland Empire and San Gabriel Valley in Los Angeles County. The City of Pomona lies east of the City of Los Angeles in the Pomona Valley, and is the home of Cal Poly Pomona. The city spans nearly 23 square miles.

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave populated areas like Pomona without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the Cal Poly Pomona campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of Cal Poly Pomona student residents in on-campus housing would also be affected by a power outage on campus and in the area. A severe power outage in Pomona would also directly affect the campus and the community.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions are:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:
- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

**Location of the Hazard**

Although power outages can take place within a certain area, as a hazard, it has the potential to occur and affect the entire planning area equally.

**Extent of the Hazard**

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached.

A power outage could affect the entire area of the campus, including the Cal Poly Pomona athletic fields, classrooms resident halls, administrative offices, virtual, telephonic and radio communications, leading to loss of lighting in campus parking structures, and creating a cascading hazard for commuters as they depart from or arrive to campus in the evening. Additionally, the university is located within proximity of highly utilized thoroughfares for the transportation of goods to throughout California.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. That said, only one recorded outage has taken place on campus. As such, the planning committee ranks the extent of the power outage hazard as **Minimal**.

**History of the Hazard**
Cal Poly Pomona did not report experiencing additional power outages in recent years, but the following power loss incident was identified on the Cal Poly Pomona website. On April 30, 2019: The University experienced power failure in multiple buildings on campus and the university was able to work with the area’s electric utility provider to return to a normal state of operations and regular classes.

**Potential Impacts of the Hazard**

Instructors, campus residents, staff, and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

**Climate Change and Energy Shortage**

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature
variance throughout the calendar year. The City of Pomona and Los Angeles County experience such outages. As such, the probability ranking for the Pomona area is **Likely**. Since the Cal Poly Pomona campus has also recorded power outage events, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

**Estimate of Potential Losses**

The data provided by Cal Poly Pomona’s State does not report any value for potential losses due to power outage. However, the university has begun implementing mitigation efforts by working with Southern California Edison to improve and modernize antiquated systems. A $30 million dollar investment to the electric utility infrastructure has been upgraded. A new electrical substation has also been leased adjacent to the campus to mitigate against power outages.

**Vulnerability Assessment Conclusions**

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at SJSU. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

**Identified Data Limitations**
Cal Poly Pomona did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.

**Volcano (Associated Air Quality)**

**Description of the Hazard**

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

**Location of the Hazard**

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of Cal Poly Pomona or Los Angeles County is within a volcano hazard zone.

**Extent of the Hazard**

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While Cal Poly Pomona does not fall within an estimated ashfall zone, lighter dustings of

---

ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As Cal Poly Pomona is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at Cal Poly Pomona.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability to the Hazard
Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For Cal Poly Pomona, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

Cal Poly Pomona is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression
actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another. The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

77 State of California Hazard Mitigation Plan, September 2018
A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

Location of the Hazard

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests, and other lands with high susceptibility to fire occurring throughout the state. Cal Poly Pomona is located along the base of the eastern edge of the San Jose Hills. Areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur to the west and north of the campus. Additionally, these fire hazard zones exist in other areas throughout Los Angeles County. These areas surrounding the valley are topographically diverse, contain heavier vegetative fuels, and often have residential development interspersed. The land in the San Gabriel Valley where the Cal Poly Pomona campus is located, is largely developed with residential and commercial land uses surrounded by low rising hills with moderate to heavy vegetation.

The area immediately to the south and east of the campus is predominately commercial and residential. The areas to the west and north include open hillsides some combined with residential land uses included. Fire Hazard Severity Zones are found throughout the campus and throughout the hillsides surrounding the campus to include Very High Fire Hazard Severity Zones (VHFHSZ).
Los Angeles County has multiple areas considered as fire hazard zones that present direct threats of burning potential in areas that are in proximity to those hazard areas. Additionally, these large areas of land that are considered to be hazardous for the potential for fire will also produce the threat of diminished or hazardous air quality due to the smoke and particulates produced in the burning process. The air quality for residents of the County and the Cal Poly Pomona campus community can be greatly affected by large fires burning in these areas.

Fire Hazards Zones surrounding Los Angeles County and the San Gabriel Valley demonstrate the broader community threat that wildfires present to the population. Fire hazard severity zones are found surrounding the populated areas of the county. This presents the potential for fire related damages and smoke inundation to occur in many areas that members of the campus community reside, are employed in, or where they recreate. Transportation routes are equally impacted causing potential added challenges.

for the campus community to get to areas if safety, get resources, or gain access to the campus.

Figure 17-11: Fire Hazard Severity Zones, Eastern Los Angeles County and Inland Empire

Extent of the Hazard

While the threat to fire directly affecting the campus is considerable, the direct effect of fire-generated smoke is also likely to occur. Fires are likely to occur in areas close enough to the campus that generate substantial amounts of smoke that could envelop the campus in the right atmospheric conditions. Fires that are large enough to generate volumes of smoke to cover great distances have the potential to affect the air quality of the San Gabriel Valley area including the campus. This will especially be the case in weather conditions creating strong offshore winds. The potential for this impact has been demonstrated during the summers of 2018, 2019, and 2020 as fires burned across the state and spread smoke over vast distances. Fires burning outside of the San Gabriel Valley and Inland Empire region have the potential to distribute smoke onto the Cal Poly Pomona campus.
The area immediately surrounding the Cal Poly Pomona campus is in direct proximity to fire hazard zones designated as a High Fire Hazard Severity Zones and Very High Fire Hazard Severity Zones. As a result, along with the history of occurrences in the surrounding area, the planning committee ranks the extent of the wildfire hazard for the campus as **High**.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 17-22: National Fire Danger Rating System\(^7^9\)

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes</td>
</tr>

or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.

<table>
<thead>
<tr>
<th>CLASS 4: Very High Danger (VH)</th>
<th>Fires start very easily and spread at a very fast rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Orange</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CLASS 5: Extreme (E)</th>
<th>Fire situation is explosive and can result in extensive property damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Red</td>
<td>Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</td>
</tr>
</tbody>
</table>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.

Figure 17-12: Air Quality Index for Ozone and Particulate Pollution

---

History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020.81 Los Angeles County also has a long history of wildfire activity primarily in the foothills and mountains of the San Gabriel Mountains, the Chino Hills, and the San Jose Hills. Wildfires occurring in Los Angeles County and the Inland Empire have resulted in hundreds of thousands of acres burned and millions of dollars in damages.

The area immediately surrounding the Cal Poly Pomona campus is in direct proximity to fire hazard zones designated as a High Fire Hazard Severity Zones and Very High Fire Hazard Severity Zones. The campus does have a history of minor wildfire activity occurring within proximity to the campus. However, the San Gabriel Valley and Inland Empire are surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Cal Poly Pomona campus has experienced multiple days of poor air quality due to fires burning in southern California mountains. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including the San Gabriel Valley. Cal Poly Pomona personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

Table 17-23: - Historic Large-Scale Fires Near Cal Poly Pomona82

---

81 California Department of Forestry and Fire Protection, Stats and Events, https://www.fire.ca.gov/stats-events/

82 City of Pomona Natural Hazards Mitigation Plan, November 2012
Potential Impacts of the Hazard

The location of the Cal Poly Pomona campus on a hillside near areas designated as High Fire Hazard Severity Zones places a threat that flame, ember, and smoke exposure from wildfire to the campus. There is potential for fire to occur from the west or north of the campus. The surrounding hillsides and valleys are composed of light to moderate fuels. The threat from fire and the impacts fire would have on the university is due to the campus being located adjacent to open hillsides and field susceptible to fire spread.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Threat or damage to on campus child care facilities
- The Kellogg House is surrounded by dense vegetation
- Structures on the northwest side of campus on South University Drive including Chilled Water Plant, Health Services, Science Laboratories, College of Agriculture, College of Science, Building One, Manor House, Palmitas Residence Hall, La Cienega Center, Los Olivos Commons, Cedritos Residence Hall, Encinitas Residence Hall, Montecito Residence Hall, Aliso Residence Hall, Alamitos Residence Hall, and the Recreation Maintenance Building.
- Substantial on-campus student resident population reside within fire hazard zone requiring evacuation in fire events
- Kellogg West Main Lodge and the Kellogg Conference Center are surrounded by dense vegetation.
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities, on campus power generation
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:
- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Los Angeles County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

**Probability of Future Occurrence of the Hazard**

Based on the wildfire threat potential in the area surrounding the Cal Poly Pomona campus and hillsides along the north and west side of the campus, including the immediate proximity to Local Fire Hazard Severity Zones listed as “Very High”, the
density of residential and commercial development, and the historic occurrences of fires, the probability of annual wildfire related damage is considered Possible.

Based on the wildfire threat potential in the area surrounding Southern California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of annual wildfire generated smoke impacts to air quality is considered Possible.

**Vulnerability to the Hazard**

The Cal Poly Pomona campus is subject to direct impact from wildfire due to the campus location within a wildland-urban interface zone. The campus is identified to reside near a designated local High Fire Hazard Severity Zone. The campus is surrounded on two sides by hillsides and open lands containing combustible vegetation combined with residential development. Additionally, vulnerabilities to the effects of wildfire would lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillsides and extending onto the campus or localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have significant impact on the campus. The campus community living or working in areas along the northern portions of the campus where dense vegetation exists along the fire hazard zones outside of campus are particularly vulnerable to effects of fire.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures. Structures with vegetation and other combustibles near the structure increases the ability of fire to spread to buildings.

Access to the west using West Temple Avenue servicing access to Walnut and Grand Ave accessing Covina could become cutoff during fire incidents. Interstate 10 and State Route 57 traverse fire hazard zones and may also be impacted by fire making those routes impassible. Access for supplies, equipment, and emergency services in addition to evacuation away from the campus would likely be forced to use alternative routes into Pomona.

The greater concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated
the reality of large wildfires producing enough smoke to fill the San Gabriel Valley and Inland Empire even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. Cal Poly Pomona students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the Cal Poly Pomona campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $355,971,530. However due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Los Angeles County, including wildfire incidents that have threatened or caused damages near the Cal Poly Pomona campus. The location of the Cal Poly Pomona campus surrounded by open hillsides with light to moderate vegetative fuels along the entire northern edges presents a threat of fire to the campus community and campus assets. The foothills and mountains surrounding Los Angeles County host environments that are ideal for the development of wildfire activity. The consequences of fires in these areas would present primary and secondary consequences to the Cal Poly Pomona campus and expose vulnerabilities on the campus and to the campus community.

The topography of the valley surrounded by mountains allows for smoke filled air to linger in the valleys of Los Angeles County area with the potential for unhealthy air quality depending on wind conditions. Fires in the watersheds of the San Gabriel, San Bernardino, and Santa Ana Mountains and the Transverse Ranges and tributaries may damage vegetation stabilizing hillsides and result in increased sediments to be discharged into the river system and reservoirs reducing their capacity and effectiveness.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.
Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, and Lightning)**

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding.\(^\text{83}\) According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”\(^\text{84}\)

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle,  

---

directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including Cal Poly Pomona.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.)
events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.90

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including Cal Poly Pomona), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.91

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.92 The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.93 These storms affect (in varying degrees) all CSU campuses, including Cal Poly Pomona.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.94 Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.95 Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.96 Severe thunderstorms are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe

90 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
91 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.97 98

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.

- **Wind storm**: marked by high wind with little or no precipitation.

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.99

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: **wind hazards** (including tornadoes), **hail**, and **lightning**. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

Wind Hazards

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\textsuperscript{100} Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” \textsuperscript{101}

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including Cal Poly Pomona).

High Winds, Strong Winds, and Thunderstorm Winds

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\textsuperscript{102}

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\textsuperscript{103}

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\textsuperscript{104}

\textsuperscript{101} Retrieved on 07.15.2021 from https://forecast.weather.gov/glossary.php?word=wind%20gust
\textsuperscript{102} Retrieved on 07.17.2021 from https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf
\textsuperscript{103} Retrieved on 07.17.2021 from https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf
Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms. However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

**Tornadoes**

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth. This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes. On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.

**Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.**

**Santa Ana Winds.** A type of wind hazard that is peculiar to Southern California is called a *Santa Ana Wind*. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico). They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape. (Note: The Wildfire hazard is profiled elsewhere in this document.)

106 Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/
108 Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions
Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

Figure 13: What Drives a Santa Ana Wind?\textsuperscript{111}

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.\textsuperscript{112}

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the

\textsuperscript{111} Retrieved on 07.14.2021 from https://twitter.com/nwslosangeles/status/933049473034579968

\textsuperscript{112} Retrieved on 07.13.2021 from https://www.fireweather.org/diablo-winds
southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.113 114 115

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.116 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.117

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the

surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\textsuperscript{118}

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{119} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

Location of the Hazard
Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including either at the Cal Poly Pomona main campus or at satellite campus facilities owned by the school. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

Extent of the Hazard
Severe weather hazards are non-spatial hazards that potentially affect all Cal Poly Pomona campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to Cal Poly Pomona reflect those of the surrounding community and County. As a result, all assets and people at Cal Poly Pomona are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Pomona (Los Angeles County), Santa Paula (Ventura County), and Chino (San Bernardino County) areas, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as \textbf{MODERATE}. See each sub-hazard below for the planning committee’s sub-type extent ranking.

\textit{Wind Hazard: Non-Rotational}
The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

Table 17-25: Beaufort Wind Force Scale

</table>
The air is filled with foam and spray. Sea completely white with driving spray; visibility very seriously affected.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{123}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the **date** that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 17-26: Fujita Tornado Scale (Pre-February 2007)\(^{124}\)

<table>
<thead>
<tr>
<th>F-Scale Number</th>
<th>Intensity Phrase</th>
<th>Wind Speed</th>
<th>Type of Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>F0</td>
<td>Gale tornado</td>
<td>40-72 mph</td>
<td>Some damage to chimneys; breaks branches off trees; pushes over shallow-rooted trees; damages sign boards.</td>
</tr>
<tr>
<td>F1</td>
<td>Moderate tornado</td>
<td>73-112 mph</td>
<td>The lower limit is the beginning of hurricane wind speed; peels surface off roofs; mobile homes pushed off foundations or overturned; moving autos pushed off the roads; attached garages may be destroyed.</td>
</tr>
</tbody>
</table>

---

<table>
<thead>
<tr>
<th>F2</th>
<th>Significant tornado</th>
<th>113-157 mph</th>
<th>Considerable damage. Roofs torn off frame houses; mobile homes demolished; boxcars pushed over; large trees snapped or uprooted; light object missiles generated.</th>
</tr>
</thead>
<tbody>
<tr>
<td>F3</td>
<td>Severe tornado</td>
<td>158-206 mph</td>
<td>Roof and some walls torn off well-constructed houses; trains overturned; most trees in forest uprooted.</td>
</tr>
<tr>
<td>F4</td>
<td>Devastating tornado</td>
<td>207-260 mph</td>
<td>Well-constructed houses leveled; structures with weak foundations blown off some distance; cars thrown and large missiles generated.</td>
</tr>
<tr>
<td>F5</td>
<td>Incredible tornado</td>
<td>261-318 mph</td>
<td>Strong frame houses lifted off foundations and carried considerable distances to disintegrate; automobile sized missiles fly through the air in excess of 100 meters; trees debarked; steel reinforced concrete structures badly damaged.</td>
</tr>
<tr>
<td>F6</td>
<td>Inconceivable tornado</td>
<td>319-379 mph</td>
<td>These winds are very unlikely. The small area of damage they might produce would probably not be recognizable along with the mess produced by F4 and F5 wind that would surround the F6 winds. Missiles, such as cars and refrigerators would do serious secondary damage that could not be directly identified as F6 damage. If this level is ever achieved, evidence for it might only be found in some manner of ground swirl pattern, for it may never be identifiable through engineering studies.</td>
</tr>
</tbody>
</table>
Table below illustrates the Enhanced Fujita (EF) Scale, currently in use. Tornadoes that have occurred since February, 2007 are classified using the Enhanced Fujita Scale.

Table 17-27: Enhanced Fujita Scale (February 2007 and Later)\(^{125}\)

<table>
<thead>
<tr>
<th>Enhanced Fujita Category</th>
<th>Wind Speed</th>
<th>Potential Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>EF0</td>
<td>65-85 mph</td>
<td>Light damage. Peels surface off some roofs; some damage to gutters or siding; branches broken off trees; shallow-rooted trees pushed over.</td>
</tr>
<tr>
<td>EF1</td>
<td>86-110 mph</td>
<td>Moderate damage. Roofs severely stripped; mobile homes overturned or badly damaged; loss of exterior doors; windows and other glass broken.</td>
</tr>
<tr>
<td>EF2</td>
<td>111-135 mph</td>
<td>Considerable damage. Roofs torn off well-constructed houses; foundations of frame homes shifted; mobile homes completely destroyed; large trees snapped or uprooted; light-object missiles generated; cars lifted off ground.</td>
</tr>
<tr>
<td>EF3</td>
<td>136-165 mph</td>
<td>Severe damage. Entire stories of well-constructed houses destroyed; severe damage to large buildings such as shopping malls; trains overturned; trees debarked; heavy cars lifted off the ground and thrown; structures with weak foundations blown away some distance.</td>
</tr>
<tr>
<td>EF4</td>
<td>166-200 mph</td>
<td>Devastating damage. Well-constructed houses and whole frame houses completely leveled; cars thrown and small missiles generated.</td>
</tr>
</tbody>
</table>

Incredible damage. Strong frame houses leveled off foundations and swept away; automobile-sized missiles fly through the air in excess of 100 m (107 yd); high-rise buildings have significant structural deformation; incredible phenomena will occur.

Based on the extent ranking factors identified (above), the planning committee ranks the extent of tornados as **LOW**.

**Extent: Hail**

The National Oceanic and Atmospheric Administration and the Tornado and Storm Research Organization (TORRO) have combined efforts to create the Hailstorm Intensity Scale. Table 17-XX provides details of this scale.

Table 17-28: Combined NOAA/TORRO Hailstorm Intensity Scale

<table>
<thead>
<tr>

<td>Baseball to Orange</td>
<td>Severe damage to aircraft body</td>
</tr>
</tbody>
</table>
Based on those extent ranking factors identified (above), the planning committee ranks the extent of the hail hazard as **LOW**.

**Extent: Lightning**

The National Weather Service (NWS) uses a Lightning Activity Level (LAL) scale to indicate the frequency and character of cloud-to-ground (C/G) lightning. The scale uses a range of 1 – 6, with 6 being the high end of the scale. Table below provides details of the LAL scale.

Table 17-29: Lightning Activity Level (LAL) Scale

<table>
<thead>
<tr>

<td>Dry lightning outbreak. (LAL of 3 or greater with majority of storms producing little or no rainfall.)</td>
<td>&gt;15%</td>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as **LOW**.

*Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events*
Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no established, objective severity scale for thunderstorms. That said, according to the Glossary of Meteorology published by the American Meteorological Society (AMS), a thunderstorm is reported as light, medium, or heavy according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;

- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;

128 Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
129 Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
**Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder). \(^{133}\) \(^{134}\)

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

**History of the Hazard**

Severe weather hazards have been an annual occurrence in Los Angeles County and on the Cal Poly Pomona campus in Los Angeles County. Severe weather hazards have also been an annual occurrence at satellite campus facilities in both Santa Paula (Ventura County) and Chino (San Bernardino County). Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\(^{135}\) For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\(^{136}\) To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**Los Angeles County**

---

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Los Angeles County since 1996.\(^{137}\) Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\(^{138}\)

- **High Wind**: at least 387 events, or approximately 15.28 events per year\(^ {139}\)
- **Strong Wind**: at least 3 events, or 0.12 events per year\(^ {140}\)
- **Thunderstorm Wind**: at least 43 events, or approximately 1.70 events per year\(^ {141}\)
- **All Wind Hazard events** (excluding Tornadoes): at least 427 events, or approximately 16.86 events per year.\(^ {142}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Los Angeles County, there have been at least 427 wind hazard events since 1996, excluding tornadoes.\textsuperscript{143} That translates to an approximate average historical frequency of occurrence of \textbf{16.86} wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 433 events) and simultaneous Database searches of all severe weather hazard events (i.e., 427 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Los Angeles County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{144} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 427 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Los Angeles County has experienced since 1996 have been costly. There have been 2 deaths and 4 injuries reported from wind hazard events (excluding tornadoes) in Los Angeles County; no property or crop damage has been reported.\textsuperscript{145}

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 12 reported events of tornadoes in Los Angeles County, which translates to approximately \textbf{0.47} tornado events per year.\textsuperscript{146}

\textsuperscript{143} National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Thunderstorm+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=LOS%2BANGELES%3A37&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA

The vast majority of tornado reports in Los Angeles County since 1996 have been of tornadoes with a severity rating of F0/EF0. Only one (1) or 12 of the tornadoes reported in has been rated F1/EF1 or higher (it was an F1 tornado that occurred in 1998); that translates to approximately 0.04 events of F1/EF1 tornadoes have occurred per year in Los Angeles County.¹⁴⁷

Historical Tornado Hazard Losses for Los Angeles County since 1996

According to the NCEI Storm Events Database, the tornado hazard events that Los Angeles County has experienced since 1996 have been minimal. There have been no deaths, or property or crop damage reported; however, 1 injury has been reported.¹⁴⁸ (Note: The F1/EF1 tornado that occurred in Los Angeles County in 1998 caused the one (1) reported injury.)

Hail

Information from the NCEI Storm Events Database indicates that since 1996, there have been 18 reported events of hail in Los Angeles County, which translates to approximately 0.71 hail events per year.¹⁴⁹ (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 19 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, over 100 miles away from Los Angeles County. The origin of this error is unknown at this time.)

Historical Hail Hazard Losses for Los Angeles County since 1996

According to the NCEI Storm Events Database, the hail hazard events that Los Angeles County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damages reported, property damage estimates have totaled approximately $3,500,000; the property damage estimate reflects one hail hazard event that occurred in 2003.¹⁵⁰ (Note: The San Diego County hail event that was included

erroneously in the search results for hail hazard events in Los Angeles County accounted
for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search
results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have
been 9 reported events of lightning in Los Angeles County, which translates to
approximately 0.36 lightning events per year.\(^{151}\)

**Historical Lightning Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Los
Angeles County has experienced since 1996 have been costly. While no property or crop
damages have been reported, there have been 2 deaths and 13 injuries attributed to
lightning hazard events.\(^{152}\)

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

**(Los Angeles County)**

Information obtained from the NCEI Storm Events Database indicates that there have
been 466 occurrences of the severe weather hazard in Los Angeles County. This
translates to 18.39 severe weather hazard occurrences per year.\(^{153}\)

Please note: Differences between the sums of individual component severe weather
hazard event Database searches (i.e., 472 events) and simultaneous Database searches of
all severe weather hazard events (i.e., 466 events) may be due to the following factors: (1)

value (i.e., 240 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Ventura County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Ventura County has experienced since 1996 have been costly. There has been 1 death associated with wind hazards; however, there have been no injuries, or property and crop damage.¹⁶³

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 5 reported events of tornadoes in Ventura County, which translates to approximately **0.20** tornado events per year.¹⁶⁴ All tornado reports in Ventura County since 1996 have been of tornadoes with a severity rating of F0/EF0.¹⁶⁵

**Historical Tornado Hazard Losses for Ventura County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Ventura County has experienced since 1996 have not generated any known losses; no deaths, injuries, or property or crop damage have been reported in Ventura County from tornado hazard events.¹⁶⁶

**Hail**

17-116
Ventura County severe weather hazard events recorded on the Storm Events Database, all deaths and injuries have been caused by wind hazard events alone. (Again, there have been no reported property or crop damages associated with severe weather hazards in Ventura County since 1996.)

San Bernardino County

Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in San Bernardino County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind**: at least 493 events, or approximately 19.46 events per year
- **Strong Wind**: at least 70 events, or 2.76 events per year
- **Thunderstorm Wind**: at least 116 events, or approximately 4.58 events per year

Historical Lightning Hazard Losses for San Bernardino County since 1996

According to the NCEI Storm Events Database, the lightning hazard events that San Bernardino County has experienced since 1996 have been costly. There have been 3 deaths and 9 injuries, and property damage estimates have totaled approximately $1,343,000; reported crop damage estimates have been negligible (i.e., $100).  

All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database (San Bernardino County)

Information obtained from the NCEI Storm Events Database indicates that there have been 796 occurrences of the severe weather hazard in San Bernardino County. This translates to 31.42 severe weather hazard occurrences per year. 

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 803 events) and simultaneous Database searches of all severe weather hazard events (i.e., 796 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for San Bernardino County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 796 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical, Aggregated Severe Hazard Losses for San Bernardino County since 1996

According to the NCEI Storm Events Database, the severe weather events that San Bernardino County has experienced since 1996 have been costly. There have been 7 deaths and 51 injuries, and property and crop damage estimates have totaled approximately $54,615,000 and $2,000,000, respectively. It is important to note that for all San Bernardino County severe weather hazard events recorded on the Storm Events Database, more than half of all deaths, the vast majority of injuries, all estimated crop damages, and approximately 96.8% of all estimated property damages have been caused by wind hazard events alone.

Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April. From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting

196 National Climatic Data Center. Storm Events Database. Retrieved 07.30.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Hail&eventType=%28Z%29+High+Wind&eventType=%28C%29+Lightning&eventType=%28Z%29+Strong+Wind&eventType=%28C%29+Thunderstorm&eventType=%28C%29+Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SAN%2BBERNARDINO%3A71&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA

up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.199 200

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Figure 17-14: Mean Annual Frequency of Santa Ana Wind events (1948-2012)201 202

Diablo Winds

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.²⁰³

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.²⁰⁴

---

²⁰⁴ Retrieved on 07.15.2021 from https://www.fireweather.org/diablo-winds
Strong sundowner wind events occur approximately **2-3 times per year**. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\(^\text{206}\)

**Historical Frequency of All Severe Weather Hazards**

The following tables show the average historical frequencies of severe weather hazard events for Los Angeles County, Ventura County, and San Bernardino County, respectively, since 1996.

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people at all Cal Poly Pomona campuses are at risk from the effects of severe weather hazards.
Please Note: The Cal Poly Pomona main campus is located primarily in an unincorporated area of Los Angeles County adjacent to the City of Pomona; however, the university owns some land within the Pomona city limits.\textsuperscript{207} As a result, hazard mitigation plans for both Los Angeles County and the City of Pomona are used as information resources for parts of this section.)

\textbf{Wind Hazards (Including Tornadoes)}

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the Cal Poly Pomona campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

\textbf{Cal Poly Pomona Main Campus, Unincorporated Los Angeles County and City of Pomona (Los Angeles County)}

According to the 2015 City of Pomona Natural Hazards Mitigation Plan (NHMP), “windstorms” (excluding tornadoes) are not a serious hazard for the city overall. However, the Pomona NHMP acknowledges that severe windstorms, originating mostly from Santa Ana wind events, can pose a significant risk to – and have a significant potential impact on – the City of Pomona.\textsuperscript{208} The 2019 County of Los Angeles All-Hazards Mitigation Plan is climate-change-focused, and does not include explicitly any severe weather hazards in its hazard identification profiles and risk assessments.\textsuperscript{209} To accommodate both hazard mitigation plans’ wind hazard assessments, as well as NCEI Storm Events Database historical frequencies, wind hazards (excluding tornadoes) are identified here as having low to medium significance for and minimal to moderate impact on both the City of Pomona and (by extension) the Cal Poly Pomona main campus. Due to their exclusion from both the city and County hazard mitigation plans, tornado hazards

\begin{footnotesize}

\end{footnotesize}
are considered to have low significance for and minimal potential impact on the city and on Cal Poly Pomona main campus areas.

**Cal Poly Pomona – Pine Tree Ranch Campus, Santa Paula (Ventura County)**

According to the 2015 Ventura County Multi-Hazard Mitigation Plan, the high wind hazard component of “winter storms” is considered to be significant, and may have a moderate potential impact on the County and on the Cal Poly Pomona main campus. Because the County is at very low risk from tornadoes, and tornadoes are not included in any hazard profile of the Plan, the potential impacts from tornadoes are considered to be minimal for the County and for the Cal Poly Pomona – Pine Tree Ranch Campus.210

**Cal Poly Pomona – Westwind Ranch Campus, Chino (San Bernardino County)**

The 2018 City of Chino Hazard Mitigation Plan does not address any severe weather hazards, as severe weather is not considered to be a hazard with significant potential to occur in the city. As a result, wind hazards are considered to be of low significance, and therefore to have a minimal potential impact on the city and (by extension) the Cal Poly Pomona – Westwind Ranch Campus.211

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

**Cal Poly Pomona Main Campus, Unincorporated Los Angeles County and City of Pomona (Los Angeles County)**

According to both the 2015 City of Pomona Natural Hazards Mitigation Plan (NHMP) and the 2019 County of Los Angeles All-Hazards Mitigation Plan, hail hazards are not explicitly identified to be significant hazards. Therefore, the hail hazard is considered to be of low significance for

---

significance and therefore to have minimal potential impact on the City of Pomona and (by extension) the Cal Poly Pomona main campus.\textsuperscript{212} \textsuperscript{213}

**Cal Poly Pomona – Pine Tree Ranch Campus, Santa Paula (Ventura County)**

According to the 2015 Ventura County Multi-Hazard Mitigation Plan, the hail hazard component of “winter storms” is considered to be a hazard that may accompany winter storms, but it is not a significant hazard in and of itself. As a result, it has a minimal potential impact on the County and on the Cal Poly Pomona – Pine Tree Ranch campus.\textsuperscript{214}

**Cal Poly Pomona – Westwind Ranch Campus, Chino (San Bernardino County)**

The 2018 City of Chino Hazard Mitigation Plan does not address any severe weather hazards, as severe weather is not considered to be a hazard with significant potential to occur in the city. As a result, hail hazards are considered to be of low significance, and therefore to have a minimal potential impact on the city and (by extension) the Cal Poly Pomona – Westwind Ranch Campus.\textsuperscript{215}

**Lightning**

Lightning strikes the United States about 20-25 million times a year.\textsuperscript{216} Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.\textsuperscript{217} Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.\textsuperscript{218} (Commercial claim payouts for lightning losses for the U.S. were not available.)

\textsuperscript{218} Retrieved on 07.21.2021 from https://www.iii.org/table-archive/20504
Cal Poly Pomona Main Campus, Unincorporated Los Angeles County and City of Pomona (Los Angeles County)

According to both the 2015 City of Pomona Natural Hazards Mitigation Plan (NHMP) and the 2019 County of Los Angeles All-Hazards Mitigation Plan, lightning hazards are not explicitly identified to be significant hazards. Therefore, the lightning hazard is considered to be of low significance and therefore to have minimal potential impact on the City of Pomona and (by extension) the Cal Poly Pomona main campus.219 220

Cal Poly Pomona – Pine Tree Ranch Campus, Santa Paula (Ventura County)

As a result, it has a minimal potential impact on the County and on the Cal Poly Pomona – Pine Tree Ranch campus.221

Cal Poly Pomona – Westwind Ranch Campus, Chino (San Bernardino County)

The 2018 City of Chino Hazard Mitigation Plan does not address any severe weather hazards, as severe weather is not considered to be a hazard with significant potential to occur in the city. As a result, lightning hazards are considered to be of low significance, and therefore to have a minimal potential impact on the city and (by extension) the Cal Poly Pomona – Westwind Ranch Campus.222

Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity.

Cal Poly Pomona Main Campus, Unincorporated Los Angeles County and City of Pomona (Los Angeles County)

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. While the 2019 County of Los Angeles All-Hazards Mitigation Plan has little (if any) explicit quantitative assessment on the probability of future occurrence of severe weather hazards, the 2015 City of Pomona Natural Hazards Mitigation Plan (NHMP) does state that windstorm events can be expected “perhaps annually” across the region.\textsuperscript{223} 224 Also, according to the NCEI Storm Events Database, some of the severe weather hazards have occurred in Los Angeles County at least once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the Cal Poly Pomona main campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the Cal Poly Pomona main campus reflect those of the surrounding community and County.

Based on the data available the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the Cal Poly Pomona main campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for the Cal Poly Pomona main campus is \textbf{HIGHLY LIKELY}.

\textbf{Cal Poly Pomona – Pine Tree Ranch Campus, Santa Paula (Ventura County)}

The 2015 Ventura County Multi-Hazard Mitigation Plan states that a “winter storm” with high winds, hail, and lightning can occur every year in the County.\textsuperscript{225} Also, according to the NCEI Storm Events Database, severe weather wind hazard events have occurred in Ventura County considerably more than once per year – at an average of 9.47 events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the Cal Poly Pomona – Pine Tree Ranch campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for Cal Poly Pomona – Pine Tree Ranch campus reflect those of the surrounding community and County.

Based on the data available from both the 2015 Ventura County Multi-Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the Cal Poly Pomona – Pine Tree Ranch campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for the Cal Poly Pomona – Pine Tree Ranch campus is \textbf{HIGHLY LIKELY}.

\begin{itemize}
\end{itemize}
once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for Cal Poly Pomona – Pine Tree Ranch campus is **HIGHLY LIKELY**.

**Cal Poly Pomona – Westwind Ranch Campus, Chino (San Bernardino County)**

The 2018 City of Chino Hazard Mitigation Plan does not address any severe weather hazards, as severe weather is not considered to be a hazard with significant potential to occur in the city. However, according to the NCEI Storm Events Database, wind hazards have occurred in San Bernardino County far more than once annually – at an average of 26.57 events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the Cal Poly Pomona – Westwind Ranch campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the Cal Poly Pomona – Westwind Ranch campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2018 City of Chino Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the Cal Poly Pomona – Westwind Ranch campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for the Cal Poly Pomona – Westwind Ranch is **HIGHLY LIKELY**.

**Cal Poly Pomona – All Campus Areas**

The probability of future occurrence of the severe weather hazard for all Cal Poly Pomona campus areas is **HIGHLY LIKELY**.

The following tables show the probabilities of future occurrence for component severe weather hazards for Cal Poly Pomona campus facilities in Los Angeles, Ventura, and San Bernardino Counties.

Vulnerability to the Hazard

People, structures, and assets at all Cal Poly Pomona campus areas are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. Cal Poly Pomona campuses also have vehicles that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the all Cal Poly Pomona campus areas. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within Cal Poly Pomona campuses are at risk from severe weather. There are approximately 429 campus buildings that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $355,971,530 for 255 buildings, and are unknown for the remaining 174 buildings. An analysis of projected dollar losses to campus buildings from severe
The populations at all Cal Poly Pomona campuses vary throughout the day. As of Fall, 2019, Cal Poly Pomona had 27,914 students and 2,650 faculty and staff. All are at risk from severe weather events, with 30,564 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to all Cal Poly Pomona campuses. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to Cal Poly Pomona.

It is evident that Cal Poly Pomona has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.

17.4 Social Vulnerability Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Pomona campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.
Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”

Table 17-36: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
</table>
| Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning? | ▪ International students  
▪ Students from out-of-state  
▪ Students in or aging out of foster care  
▪ Populations experiencing homelessness |
| Which population groups are most difficult to reach in an event?           | Populations who speak English as a second language                               |
| Which population groups have little/limited support networks if impacted by an event? | ▪ Vulnerable populations with high levels of inequity  
▪ Populations with limited digital connectivity |

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food
security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (undocumented, DACA, etc.), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as Very High, High, Medium, Low
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as Yes, No, In Progress, NA

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Those first identified as most difficult to reach in emergency communications are those with ESL language barriers, notably the top five languages of Spanish, Arabic, Chinese, Japanese and Korean.
- There is a communications plan that will be turned into an EOP annex.
- There is a MOU with a food vendor for the campus and while a planning has taken place, an annex for the dining services needs to be added into the EOP.
- There have been trainings for evacuation coordinators on how to help the AFN populations and there is an effort to add a component for bringing representatives into the EOC.
- COVID has “opened their eyes” and there is a need to add digital equity into the EOP.
- They have just started thinking about the impact of disasters on the living/shelter situation of the international students.
- There is a low concern regarding the students who are immigrants or have immigration status issues, as they are anticipated to have families and they will go back to their homes.
- If LGBTQI clubs reached out for emergency management training they would provide it, but they don’t reach out the groups specifically.
- For transportation, most students have cars and ride shares to the metro and bus lines.
- A noted issue was coordination with a broader spectrum of partners of the campus for planning purposes.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience
to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

*Drought*

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.229 Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be

---

more intense, even leading to “megadroughts” in the western states. Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.231

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

_________________________

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 232

**Hazardous Materials**

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates

primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease. Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.

**Landslides**

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied buildings which makes it a function of structural vulnerability and therefore, indirect. The degree of vulnerability to landslides by an individual considered at high risk, or even the general populations, also depends on human behavior, including many of the traditional social factors that are difficult to measure such as situational awareness, prior knowledge of hazards, and decision-making capabilities.

Landslides can result in primary lifeline failures through the loss of roads or power and communication lines. Transportation routes are often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods. Risk from landslide relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

---

233 https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/

Power Outage/Public Safety Power Shutdowns (PSPS)

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

Wildfire

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity.

Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone,

carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.\textsuperscript{239}

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.\textsuperscript{240}

**Hazard Mitigation and Emergency Management Planning**

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

18.1 University Profile

University History

CSU Sacramento or Sacramento State University came into existence in 1947. The current site has not always been the location CSU Sacramento has been at. Originally, Sacramento State was known as Sacramento State College and was located on the grounds of the current Sacramento City College. The site of the current campus was broke ground on May of 1951. Today, Sacramento State boasts seven academic colleges and a college of continuing education.

Sacramento State College, it is the eleventh oldest school in the 23-campus California State University system. The university enrolls approximately 31,500 students annually. The university offers 151 different Bachelor’s degrees, 69 Master’s degrees, 28 types of teaching credentials, and 5 Doctoral degrees.

CSU Sacramento is designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The ABA Administrative Council serves as an advisory body to the vice president and chief financial officer (CFO). Information is disseminated through this body, and it is expected that members of the Council convey this information to managers and staff of their individual ABA families – Budget Planning & Administration, Facilities Management, Financial Services, Human Resources, Sacramento State Police Department, Resource & Organizational Management, Risk Management Services, University Support Services and the Vice President for Administration, which includes Administrative Operations and Auditing & Consulting Services. This group is also responsible for initiating, implementing, and enhancing ABA’s organizational development, which includes strategic planning. This encompasses a variety of activities that promote cultural change to meet the evolving needs of the campus, employee productivity, morale and communications, and advice on other matters brought forward for consideration.

The Administrative and Business Affairs Council serves as an advisory body to the Vice President for Administration. Information is disseminated through this body for distribution to managers and staff of ABA families - Budget Planning & Administration,
Facilities Management, Financial Services, Public Safety, Risk Management Services, Resource & Organizational Management, University Transportation, Parking & Support Services, and the Office of the Vice President for Administration which includes Administrative Operations and Auditing & Consulting Services. The Council is also responsible for initiating, implementing, and enhancing the ABA Change Management Program, which includes Strategic Planning. This encompasses a variety of activities that promote cultural change to meet the evolving needs of the campus, employee productivity, morale and communications, and advice on other matters brought forward for consideration. Members of the Council share operational issues, customer concerns, status of projects and other matters pertinent to ABA. ABA Administrative Council members are expected to be proponents for change to assist in the development of a culture of service, efficiency and professionalism in Administration & Business Affairs, through the support for and advancement of the concepts listed below.

The ABA Management Council is an advisory group to the vice president and the ABA Administrative Council on all matters pertaining to the ABA division’s operations and delivery of customer service. The ABA Management Council will serve as an advisory group to the vice president and the ABA Administrative Council on all matters pertaining to the ABA division’s operations and delivery of customer service. Input from members is expected, and dissemination of critical information to staff will be conveyed through this group regarding changes in policies and procedures, mandates, employee programs and other matters brought forward for discussion.

The ABA Professionals Team, consisting of all ABA managers and staff, serves as an advisory group to the Vice President for Administration and the ABA Administrative Council, providing input on the operations of the division from the unit perspective. The vice president communicates critical information from the president or President’s Cabinet, divisional changes and program and budget information through team meetings each semester, or more frequently as needed.

University Mission

“As California’s capital university, we transform lives by preparing students for leadership, service, and success.”

CSU Sacramento outlines six strategic priorities in support of their goals by focusing on students’ success, providing opportunities for scholarship, research, and creative activity, diversity and inclusion. Additionally, proactively engage with the community, on-going innovation, maintaining integrity and remaining accountable to its community and stakeholders.

University Location

The campus sits on 300 acres, covered with over 3,500 trees and over 1,200 resting in the University Arboretum. The university is the site of two National Register of Historic Places, the Julia Morgan House and the terminus of the Pony Express. CSU Sacramento is located in the capital city of California, within the Sacramento County.
University Population

In the Fall of 2019, the total enrollment exceeded over 31,000 students. Latino students made up 34% of the student population, with White students making up 19% of the student population.

18.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate.

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.
18.3 Hazard Identification and Risk Assessment

Overview of California State University, Sacramento History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 18-1 (following).

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely**- 76%-100% that the hazard would occur annually.
- ** Likely**- 50%-75% that the hazard would occur annually.
- **Possible**- 11%-49% that the hazard would occur each annually.
- **Unlikely**- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 18-2 below.)

**Descriptions of Identified Communicable Disease Hazards at Sacramento State**

Sacramento State has identified one (1) communicable disease hazard that has had the greatest impact on campus – COVID-19. The following is a brief description of the communicable disease hazard at Sacramento State.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.  

Location of the Hazard

Communicable diseases have the potential to affect the entire CSU Sacramento (Sacramento State) planning area equally. As a result, the communicable disease hazard can be found at the Sacramento State campus located in Sacramento, CA (Sacramento County). The communicable disease hazard can also be found at four (4) offsite facilities owned and run by Sacramento State. Two (2) of these facilities – Hornet Commons (upcoming new student housing) and Folsom Hall – are located adjacent to the central campus. A third facility, the Julia Morgan House Event and Conference Center, is located approximately 3 miles away from the central campus. The fourth facility, The Sacramento State Aquatic Center, is located 14 miles away from the main campus, in Gold River, an unincorporated area in Sacramento County. Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) the Sacramento State main campus and offsite facilities are at risk of exposure to the communicable disease.

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be

---

allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For Sacramento State, approximately 6% of its 31,156 enrolled students (or 1,869 students) reside in student housing.  

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 22-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

---

7 California State University. CSU Campus Match. Retrieved 04.30.2021 from: https://www2.calstate.edu/attend/campuses/campus-match/Pages/campus-match.aspx
The Extent of CSU Sacramento Communicable Disease Hazards Except COVID-19:

Besides COVID-19, there was no information provided on other communicable disease hazards on campus.

The Extent of CSU Sacramento COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.  

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 293 cases of COVID-19 at CSU Sacramento. Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a

---

result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 18-5 and 18-6 show campus-level and County-level COVID-19 Case data for Sacramento State. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics have (and will continue to have) direct impact on life, health, and safety across the CSU system (including the Sacramento State campus). The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of Sacramento State students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including Sacramento State) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the

procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 18-6: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 18-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3

category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 18-7: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

<th>Other Hemorrhagic Diseases</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

**Probability of Future Occurrence of the Hazard**

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.
Table 18-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 18-8: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence. Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at CSU campuses. CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, CSU - Sacramento had 31,156 students and additional faculty and staff.) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic at Sacramento State

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

15 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csustystem/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

16 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csustystem/faculty-staff/employee-profile/csustystem/workforce/Pages/employee-headcount-by-campus.aspx
At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including Sacramento State) are at risk of developing an extreme incidence of COVID-19 and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

Economic Impact of COVID-19 Pandemic on CSU Financial Health

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 18-2 below for the economic impact to the Sacramento State campus). Several CSU campuses saw refund losses surpass $10 million. (See Figure 18-2.)

Figure 18-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs

---

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 18-11.) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

**Vulnerability Assessment Conclusions**

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable
disease hazard. *If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time.* This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 18-12 below for the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system (including Sacramento State). In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Dam and Levee Failure**

**Description of the Hazard**

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water.\(^{24}\) Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from over topplings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures

---

potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

Sacramento County is home to a variety of flood control facilities and levee systems mostly along the river systems including along the American River and Sacramento River. The American River drains a large portion of the mountains of the Sierra Nevada draining runoff towards the Sacramento River. The Sacramento River drains a number of northern California watersheds from the Sierra Nevada, Coastal Range, and Cascade Mountains passing 4-5 miles west of the CSU Sacramento campus. The Sacramento River and tributary rivers are regulated by a number of large dam facilities that could pose a hazard to the Sacramento region but do not include the CSU Sacramento campus within their inundation zones. These facilities include Lake Shasta and Oroville Lake.
Figure 18-3A: Dams and Levees near CSU Sacramento

Figure 18-4B: Dams and Levees near CSU Sacramento Folsom
The American River is a year-round flowing natural river. The campus sits at a bend of the river and in a location where the river channel narrows slightly from the channel width upstream. The river feeds into the Sacramento River 6 ¾ miles downstream from the campus and eventually into the Pacific Ocean through the San Francisco Bay. The American River is lined with levees on both banks. The campus is surrounded by dense residential and commercial land uses. Critical transportation networks serving the campus cross the river systems and levees protecting the Sacramento community.
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
Low hazard potential dams are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

<td>High Hazard</td>
</tr>
</tbody>
</table>

The CSU Sacramento campus lies within the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the entire campus is expected to be impacted by the inundation area. The inundation area is expected to spread water across large areas of the Sacramento region. There are multiple transportation corridors that lie within the dam inundation zones that could compromise transportation routes and areas the campus community reside or work. Based on the above factors, the planning committee ranks the extent of the hazard as Moderate.

**Extent – Levee Failure**

Levees are used along numerous rivers, flood control channels, and other waterways including the American River and Sacramento River. The CSU Sacramento campus lies within the levee flood protected area. Recent modifications to the levees lining the American River have been completed enhancing the protection level in these areas. The CSU Sacramento campus additionally lies between the levee lining the southern bank of the American River and a levee on the western border of the campus. Flood waters that may release from the American River may back up further on campus as the water is held by the secondary levee. Based on the above factors, the planning committee ranks the extent of the hazard as Moderate.

**History of the Hazard**

There are no records of dam or levee failures in areas that present a threat to the CSU Sacramento campus. However, Sacramento County has experienced the following levee failures elsewhere in the County:

Table 18-13: Sacramento County Dam or Levee Failures

<table>
<thead>
<tr>

<th>Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>June 1972</td>
<td>Andrus Island Levee</td>
<td>Unknown</td>
<td>Federal Disaster DR-342</td>
</tr>
</tbody>
</table>

While there have been no dam failures in Sacramento County, Folsom Dam has experienced events that have compromised the dam’s functional capabilities. On July 17, 1995 spillway gate #3 failed. This resulted in increasing flows into the American River significantly. No flooding downstream occurred due to the failure of the gate. On May 15, 1997, Folsom Dam experienced cavitation damage to the river outlets. A large hole developed in one of the dam conduits, Minor damage was discovered in five other conduits. No flooding occurred as a result of this incident.

Potential Impacts of the Hazard

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

The area downstream from the Folsom and Nimbus Dams includes the populated areas of Sacramento County. CSU Sacramento resides immediately adjacent to the American River and is within the dam inundation zone for the Folsom Dam. Additionally, the inundation zone covers a large portion of Sacramento County providing that those members of the campus community who reside or are employed in these areas would be heavily impacted. The campus would experience the same effects from a dam inundation...
event that would be experienced by the broader region. In addition to damages resulting from the sudden release of water, this would also be in the form of transportation routes and other community critical infrastructure being impacted by the inundation. This specific hazard would substantially alter the ability of the campus to maintain operations as damages would be extensive, the campus community in these areas would be heavily affected with the loss of life and homes, and student financial capacity to support ongoing education being diminished.

**Levee Failure Impacts**

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

**Probability of Future Occurrence of the Hazard**

Sacramento County is determined to be at risk from dam and levee failure in many parts of the county. The location of the CSU Sacramento campus is on the American River, 21 miles downstream from the Folsom Dam. The American River serves as the eastern boundary of the campus. There are multiple levees in proximity to the campus and thus the campus is within a levee protected zone. There are no official recurrence intervals that
have been calculated for dam or levee failures. Based on historical experience and occurrences, the likelihood of this hazard is low.

The probability of future occurrence for both dam and levee failures is **Unlikely**.

**Vulnerability to the Hazard**

The CSU Sacramento campus is subject to the effects of flooding resulting from compromised dams and levees. The effects would likely be mostly indirect affecting members of the campus community and regional transportation networks and services. However, the campus is located within the dam inundation zone for the Folsom and Nimbus Dams. In the case of dam failure, the amount of time to respond to the needs of the campus community prior to inundation will be limited.

The most significant challenge regarding dam failures is they generally result in catastrophic outcomes. Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

Vulnerability to a dam or levee failure on the CSU Sacramento campus will vary depending on when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

The maximum total replacement costs due to dam and levee failure are **unknown**, as estimated campus facility and structure costs were not available for CSU Sacramento.
Vulnerability Assessment Conclusions

While the occurrence of dam failures has not been historically relevant near the CSU Sacramento campus, the potential for hazards related to the region’s dams still exist. The Sacramento area has experienced threats to its levee systems throughout a number of events. The consequences of a dam failure would generate catastrophic results to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.

Drought

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry
period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.

- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - Sacramento) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified throughout Sacramento County and on the CSU Sacramento campus. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to the campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously in the state, with 80-100% of the state impacted for 12 of the last 20 years.  

Extent of the Hazard

Given the historical occurrence of severe drought impacts throughout Sacramento County (which includes the campus planning area) and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire CSU system-wide planning area, the potential impacts are variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities historically impacted by drought within each jurisdiction.

In addition, drought-related land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30 feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Though not having occurred on campus, these impacts remain issues of concern for the campus over the long term.

For CSU – Sacramento, the extent of the hazard is Moderate (corresponding to D1-D2 on the extent scale below) and addressed through water conservation and conversion to drought resistant landscaping. However, the campus planning committee recognizes that the potential for more severe conditions exists and is tied to regional water resource vulnerabilities tied to Sacramento and American rivers, and water retention infrastructure.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

Table 18-14: Impacts of Drought Levels as Determined by US Drought Monitor

<table>
<thead>
<tr>
<th>Category</th>
<th>Impact</th>
</tr>
</thead>
<tbody>
<tr>
<td>D0</td>
<td>Soil is dry; irrigation delivery begins early</td>
</tr>
<tr>
<td></td>
<td>Dryland crop germination is stunted</td>
</tr>
<tr>
<td></td>
<td>Active fire season begins</td>
</tr>
<tr>
<td></td>
<td>Winter resort visitation is low; snowpack is minimal</td>
</tr>
</tbody>
</table>

| D1 | Dryland pasture growth is stunted; producers give supplemental feed to cattle |
|    | Landscaping and gardens need irrigation earlier; wildlife patterns begin to change |
|    | Stock ponds and creeks are lower than usual |

| D2 | Grazing land is inadequate |
|    | Producers increase water efficiency methods and drought-resistant crops |
|    | Fire season is longer, with high burn intensity, dry fuels, and large fire spatial extent; more fire crews are on staff |
|    | Wine country tourism increases; lake- and river-based tourism declines; boat ramps close |
|    | Trees are stressed; plants increase reproductive mechanisms; wildlife diseases increase |
|    | Water temperature increases; programs to divert water to protect fish begin |
|    | River flows decrease; reservoir levels are low and banks are exposed |

| D3 | Livestock need expensive supplemental feed, cattle and horses are sold; little pasture remains, producers find it difficult to maintain organic meat requirements |
|    | Fruit trees bud early; producers begin irrigating in the winter |
|    | Federal water is not adequate to meet irrigation contracts; extracting supplemental groundwater is expensive |
|    | Dairy operations close |
|    | Marijuana growers illegally tap water out of rivers |
|    | Fire season lasts year-round; fires occur in typically wet parts of state; burn bans are implemented |
|    | Ski and rafting business is low, mountain communities suffer |
|    | Orchard removal and well drilling company business increase; panning for gold increases |
|    | Low river levels impede fish migration and cause lower survival rates |
|    | Wildlife encroach on developed areas; little native food and water is available for bears, which hibernate less |
|    | Water sanitation is a concern, reservoir levels drop significantly, surface water is nearly dry, flows are very low; water theft occurs |
|    | Wells and aquifer levels decrease; homeowners drill new wells |
|    | Water conservation rebate programs increase; water use restrictions are implemented; water transfers increase |
### History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous. According to the US Drought Monitor, Time Series data, Sacramento County experienced eight drought periods covering 12 years from 2000-2021, which includes the CSU - Sacramento footprint. The 2012-2017 drought period resulted in severe reductions in water supply leading to campus water restrictions and impacts to the campus landscape.

Figure 18-6: Periods of Drought in Sacramento County, CA, 2001 – 2021

---

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

Source: https://droughtmonitor.unl.edu/data/timeseries
Source: https://droughtreporter.unl.edu/advancedsearch.aspx

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 29

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions has been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on Sacramento County which includes the CSU - Sacramento campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent. 31

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought

throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the CSU - Sacramento campus planning area is a potential reduction in water availability for the regional and municipal area tied to the campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - Sacramento to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of agricultural research crops and field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. However, the wildfire hazard is analyzed separately in this plan. (See wildfire section below).

In reviewing the occurrences of drought for Sacramento County (which includes CSU - Sacramento), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2014-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - Sacramento, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data are currently available for tree mortality on campus; however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and

buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area. 

At present, drought related damage to campus buildings and infrastructure at CSU - Sacramento has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - Sacramento is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Sacramento. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Probability of Future Occurrence of the Hazard

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence in the state in any given year. Given that CSU - Sacramento lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Sacramento campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, all stakeholders at geographic levels from the state down to the CSU - Sacramento planning area, potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water
withdrawals have been occurring at a deficit rate of 1 – 2 million acre-feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

### Vulnerability of Populations

Drought vulnerabilities include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerability measures apply to the students, faculty and staff of the CSU - Sacramento campus.

### Property Vulnerability

Drought vulnerabilities include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerability measures apply to the properties of the CSU - Sacramento campus.

### Natural Environment Vulnerability

The historical and potential impacts of drought on the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

---

The core issue shaping drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for CSU - Sacramento’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of Sacramento and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**
Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.

**Earthquake**

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to
these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU Sacramento is located in the southern Sacramento Valley. In general, fault systems extend along the mountain ranges on the eastern and western edges of the valley a distance from CSU Sacramento. There are no known fault systems in the immediate area surrounding the campus.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 85 miles west of the CSU Sacramento campus. In addition to the San Andreas Fault, the Coastal Ranges and Sierra Nevada Mountains are home to or near additional fault systems with the potential to generate strong ground shaking. The Calaveras Fault traverses south to north traversing through the eastern portions if the San Francisco Bay Area extending 60 miles southwest of the CSU Sacramento campus. The Hayward Fault traverses the East Bay communities of Hayward through Berkeley 62 miles southwest of CSU Sacramento. The Green Valley Fault extends along the eastern slopes of the Coastal Ranges to the northwest into the area of Lake Berryessa 40-45 miles west of the CSU Sacramento campus. The 290-mile long Great Valley Fault extends along the eastern base of the Coastal Ranges from Kettleman City north to Orland 30 miles west of the CSU Sacramento campus. The Swain River-Spencerville Fault extends through the foothills of the Sierra Nevada Mountains 28 miles to the northeast of the campus. There are numerous additional faults in the area on all sides of the campus.
The CSU Sacramento campus does not reside in areas designated to be liquefaction zones.

**Extent of the Hazard**

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity, and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave.
during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

- **Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb. Damage great in substantial buildings, with partial collapse. Buildings shifted off foundations.**

- **Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations. Rails bent.**

The graph below (Figure 18-8) illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

#### Figure 18-9: Earthquake Magnitude and Equivalent Energy Release

![Graph Showing Earthquake Magnitudes and Equivalent Energy Release](https://www.usgs.gov/media/images/graph-showing-earthquake-magnitudes-and-equivalent-energy-release)

---

Given that earthquakes in this region have remained minor in intensity and infrequent, and that the campus is not located in a liquefication zone or near any fault systems, the planning committee ranks the extent of the hazard on the campus as **Low**.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Sacramento County also has a limited history of earthquake activity particularly in the central part of the County including where CSU Sacramento is located. Earthquakes in this region have remained minor in intensity and infrequent. Sacramento has felt shaking from earthquakes from other regions but have not resulted in damages.

**Potential Impacts of the Hazard**

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. A major earthquake in the Sacramento area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Sacramento could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Sacramento could result in extensive casualties, expansive structural damages, panic, widespread utility outages,

---

39 Sacramento County Local Hazard Mitigation Plan, October 2016
communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Sacramento region limiting immediate assistance that the campus may normally expect.

Local impacts to CSU Sacramento campus caused by an earthquake could include:

- Damage to levees surrounding campus
- Damage to upstream flood control systems on American River
- Damage to adjacent water treatment facility and potential hazardous materials release
- Damage and secondary fires to commercial and industrial buildings to the west of campus
- Potential hazardous material releases on and off campus
- Damage to rail lines along western boundary of campus
- Infrastructure damage to freeway system
- Structural damage to bridges over waterways and flood control channels
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to regional levees
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The
likelihood for the fault systems surrounding Sacramento is included in the following table.

Table 18-19: Major Potentially Active Faults in Proximity to CSU Sacramento

The Sacramento area is not known to be a seismically active area. However, the region is located between two active seismic zones in the Sierra Nevada Mountains and the San Francisco Bay Area. While no major earthquakes have been recorded within Sacramento County, the region has felt shaking from earthquakes located in other parts of Northern California. Based on the earthquake shaking potential in the Sacramento area, the proximity to the fault systems listed above, the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region tend to remain to the west along the Coastal Ranges and to the east in the Sierra Nevada Mountains. Many of these cross major transportation routes potentially reducing the availability of access and the supply chain. However, Sacramento is likely less vulnerable to the direct effects of earthquake as known fault systems are removed from the area. The geographic location of Sacramento sits at the base of river systems that have deposited sediment from the surrounding mountains. In many cases, these sediment-based soils are loose and expose the potential for liquefaction. The soils of the area surrounding the campus are described by

40 Sacramento County Local Hazard Mitigation Plan, October 2016

the Local Hazard Mitigation Plan as generally being not conducive to significant liquefaction.

The known fault systems generating the threat to Sacramento generally exist to the east and west of the city but do not cross into the city including the CSU Sacramento campus. The distance to these surrounding systems helps mitigate significant vulnerabilities in the event a seismic event was to occur on those systems. In the event of an earthquake occurring in the region on an unknown system, the potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the CSU Sacramento campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the city. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with sheltering and care of those unable or unwilling to return to their homes. Damages to the homes of the members of the campus community may place greater demands on campus resources and capabilities in the short-term period following a seismic event.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable
populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

The maximum total replacement costs due to earthquake are unknown, as estimated campus facility and structure costs were not available for CSU Sacramento.

**Vulnerability Assessment Conclusions**

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the Sacramento area and the CSU
Sacramento campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU Stanislaus campus and community.

In the event that a major earthquake was to strike along the fault systems surrounding Sacramento, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Sacramento County region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

Vulnerabilities will be seen in the physical infrastructure on the campus and the human population of the campus community. Campus infrastructure is vulnerable to severe shaking particularly in areas where the ground is loose or susceptible to liquefaction. Specifically older buildings, masonry constructed buildings, and other structures susceptible to shaking related damage are the most vulnerable. Communication systems, computer networks, and other electronic systems may be vulnerable when overwhelmed by increased demand during emergencies or by shaking related damages. The people of the campus community are vulnerable to effects of intense shaking in the form of injuries from falling debris, exposure to secondary floods or fires, loss of employment, extreme disaster induced stress, and loss of access to critical services or social contacts.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.
Erosion

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another”. Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable.

Location of the Hazard

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area, such as the American River, which is adjacent to the campus. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across all those areas of the campus with erosion-prone characteristics. Currently, no such locations have been identified on campus, though campus leadership may consider investigating whether such locations are present on campus in the future.

Extent of the Hazard

There is no published scale of severity or extent for this geologic hazard. If conditions are favorable, erosion is likely to occur. Sacramento County considers waterway bank erosion to be limited in extent, occurring in less than 10% of the County. However, the number of high-risk erosion sites identified by the USACE in an annual erosion inventory of the Sacramento River continues to grow each year. Given no record of occurrence of erosion on campus and ongoing monitoring efforts, the planning committee ranks the extent of the hazard as Low.

History of the Hazard

While there have been no recorded incidents of erosion on the CSU Sacramento campus, several stormwater projects have already been put into place on campus to reduce sediment loads and prevent erosion in the American River.

Potential Impacts of the Hazard

Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, the probability of at least a limited degree of erosion taking place somewhere on the campus is **High** over the long term.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Sacramento infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion.

In the wider Sacramento community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

Vulnerability Assessment Conclusions

While the ability to predict future erosion on the CSU Sacramento campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Heat**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.\(^{43}\)

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.\(^ {44}\) As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.\(^ {45}\)

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.\(^ {46}\) In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.\(^ {47}\)

**Location of the Hazard**

Extreme heat events are a non-spatial hazard and may occur throughout the Sacramento State campus.

**Extent of the Hazard**

\(^ {45}\) Ibid.

Extreme heat has a wide range of extent and severity markers and characteristics. In the City of Sacramento, monthly average maximum temperatures in June through October range approximately from the low 80s to the mid-90s. Temperatures at or above 90° F are common during the summer in Sacramento. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded in the City of Sacramento is 111° F. The city reached this record during a statewide heat wave in July 2006 during a consecutive stretch of triple-digit temperatures, and again on August 15, 2020 during another stretch of statewide heat waves, which caused rolling blackouts to maintain electrical grid stability. Given five extreme heat events from 2006-2020, and the historical impacts to the electrical grid and infrastructure, the planning committee ranks the extent of the hazard as Moderate.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach those criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 18-9 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.
Table 18-21: Health Risks Associated with Heat Index

</tbody>
</table>

History of the Hazard

Based on data gathered from the NCDC and the National Centers for Environmental Information (NCEI) Storm Events Database, there have been five excessive heat events in Sacramento County since 1959, but all occurring from 2006 - present.

**July 2006:** the highest daily temperature recorded in the City of Sacramento of 111° F was reached during a statewide heat wave with a consecutive stretch of triple-digit temperatures

**July 5, 2007:** This was one of the driest summers on record for the state of California, which fueled at least 9,000 separate wildfires for the year.

**June 18, 2017; August 1, 2017:** A lengthy heat wave affected large parts of the western United States during the summer of 2017, with record-breaking temperatures in many major metro areas hitting 115° F or higher. Temperatures in Sacramento reached 104° F or higher on several consecutive days in June.

August 15, 2020: Another stretch of statewide heat waves caused rolling blackouts to maintain electrical grid stability. 111° F was reached.

Potential Impacts of the Hazard

---

During an excessive heat event, Sacramento State may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

**Probability of Future Occurrence of the Hazard**

Hot summer temperatures above 90° F are common in the City and County of Sacramento. Notably, the County of Sacramento also includes excessive heat as a critical hazard that is highly susceptible to influence from climate change. It is highly likely that hot days will occur annually. Based on hazard history of extreme heat events, (5 events in the past 17 years) it is possible that an extreme heat event will occur annually.  

**Vulnerability to the Hazard**

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result. This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Sacramento State is aware of the potential for extreme heat events. During the summertime, the school holds minimal classes to keep students and faculty off-campus.

---

and runs on “summer hours” to keep staff from working outside during the hottest hours of the day. The campus has not been affected by power shut-offs in recent memory. Therefore, while this is a hazard that the campus may experience with regularity, the campus has ample familiarity with heat events to handle the risks and vulnerabilities.

**Estimate of Potential Losses**

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

**Vulnerability Assessment Conclusions**

While the ability to predict future heat events at the Sacramento State campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), areas of North-Central California have warmed approximately 1.5 – 2 degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.52

---

**Cold**

**Description of the Hazard**

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.53

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.54 This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

---

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underlying tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes. It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases. The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6°F. Hypothermia occurs when your body temperature falls below 95°F. As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

Location of the Hazard

Extreme cold events are a non-spatial hazard, and may occur at the Sacramento State campus.

Extent of the Hazard

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in the City of Sacramento are typically in the low 40s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in Sacramento was 18°F on December 11, 1932. Based on no history of extreme cold and just 6 frosty/freeze events since 1968, the planning committee ranks the extent of the hazard as Low.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30°F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure 18-9 (following) depicts the National Weather Service’s methodology for determining the

56 Ibid.

wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow).
In 2011, the National Weather Service introduced an experimental program that issued warnings for extreme cold events, independent of other severe weather warnings. The test areas included North and South Dakota and Minnesota. However, in 2012, after a single season of use, the program was abandoned, based on reports of confusion among test audiences.\(^{59}\)

**History of the Hazard**

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, Sacramento County has had six frost/freeze events, dating back to 1998, but no extreme cold hazards. \([Records\ for\ this\ hazard\ were\ first\ recorded\ in\ 1996]\).

**Potential Impacts of the Hazard**

Should an extreme cold event occur, Sacramento State might experience impacts due to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

**Probability of Future Occurrence of the Hazard**

The City of Sacramento has experienced freeze/frost events but has never experienced an extreme cold event. Due to the campus’s location in a temperate climate, it is **Unlikely** that this hazard will occur annually.

**Vulnerability to the Hazard**

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more likely to suffer illness or death as a result.60 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Sacramento State is aware that there is a low chance of an extreme cold event in the Sacramento area.

**Estimate of Potential Losses**

Based on the previous historical occurrences of extreme cold events, annualized losses are considered to be negligible. In an extreme cold event, loss of human life or health impacts are a greater concern than is property damage.

**Vulnerability Assessment Conclusions**

While the ability to predict future extreme cold events at the Sacramento State campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), areas near Sacramento have warmed

approximately 1.5 – 2 degrees on average over the last century, with less rainfall. This may lead to fewer frost/freeze events in the future.\textsuperscript{61}

**Identified Data Limitations**

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

**Flood**

**Description of the Hazard**

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the

environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Floods can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.
Atmospheric Rivers

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California, they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.

Figure 18-12: Introduction to Atmospheric Rivers

---------------------------

Location of the Hazard

Sacramento lies in the heart of the Sacramento Valley between the Sierra Nevada Mountains and the Coastal Ranges. The city is established at the confluence of the Sacramento and American Rivers. These river systems and the regional creeks have been identified as the primary flood sources for Sacramento County. The Sacramento River watershed encompasses more than 27,000 square miles of drainage or approximately 17% of the land area of California carrying 30% of the state’s water surface water. The watershed receives the majority of its water from snowfall generating 22 million acre-feet of surface water run-off into the Sacramento River and eventually the San Francisco Bay. The American River watershed is a portion of the larger Sacramento River watershed drains an area of 2,200 square miles into the Sacramento River through the City of Sacramento.

Figure 18-13: Flood Hazard Areas in Sacramento, CA
The CSU Sacramento campus is located immediately adjacent to the American River. The American River forms a bend turning direction at the point of the campus. Levees protect both sides of the river and form the boundary between the campus and the river. The American River drains Folsom Lake through Folsom Dam. Folsom Dam sits 21 miles upstream from the campus. The CSU Sacramento campus is entirely located in a designated Zone X: Area with Reduced Flood Risk Due to Levee. The access routes into and out of the campus are also found in areas primarily designated as Zone X: Area with Reduced Flood Risk Due to Levee.

Figure 18-14: Flood Hazard Zones Around CSU Sacramento
Extent of the Hazard

The CSU Sacramento campus is entirely located in a designated Zone X: Area with Reduced Flood Risk Due to Levee. The access routes into and out of the campus are also found in areas primarily designated as Zone X: Area with Reduced Flood Risk Due to Levee. However, although the CSU Sacramento campus resides in a minimally threatened flood zone that is protected by levees, flood events are still possible and isolated heavy precipitation events can still pose localized flooding hazards. Access in and out of the campus may become compromised in flooding events on or off campus. There are specific buildings and areas of the campus that are low lying and have a greater risk for isolated flooding. Based on these factors, the planning committee ranks the extent of the hazard as Low to Moderate.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBMs), Flood Insurance Rate Maps (FIRMs), and Flood Boundary and Floodway Maps (FBFMs). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood

---

zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 18-22: Flood Zone Designations and Descriptions

</table>
History of the Hazard

Flooding in Sacramento County and the broader Sacramento Valley region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the CSU Sacramento campus. On campus, heavy rainfall events can produce isolated areas of flooding and ponding, though no record of flooding events are reported specifically for the campus.

The following flood summaries are provided by the Sacramento County Local Hazard Mitigation Plan and the Sacramento Area Flood Control Agency (SAFCA). The CSU campus was not flooded during the events (below), however, the threat of flooding

---

66 Sacramento County Local Hazard Mitigation Plan, October 2016
continued to exist during these periods as the American River was also flowing at high levels for long durations of time placing tremendous stress on the levee system. These events did cause localized flooding within the neighborhoods surrounding the campus.

Flooding in January of 1995 was caused by heavy rains over a large portion of northern California including the Sacramento area. Flood damage was reported throughout much of the county, but the most severely impacted area was in the Arcade, Morrison, Florin, and Dry Creek areas. The county received both a governor’s proclamation and a presidential disaster declaration.

The January 1997 flood was the largest flooding event Sacramento County since the 1986 flooding. Counties throughout northern California experienced widespread flooding condition, levee breaks, and local evacuations. The series of tropical storms that contributed to this round of flooding also contributed to rapid snow melt in the Sierra Nevada Mountains increasing the volume of water entering into the Sacramento Valley.

The winter of 2017 brought continuous storms into northern California including the Sacramento area. A series Atmospheric River storm systems began in January of 2017 and continued through February. These storms caused rivers to reach high levels, reservoirs to fill, and the limits of flood control systems to be tested. The Sacramento Weir was fully opened for the first time in 11 years, levees along the Cosumnes River were compromised, and the Oroville Dam spillway failed.

Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
• Employment losses
• Agricultural (crops and livestock) damages or destruction
• Environmental damage
• Prolonged periods of necessary dewatering
• Flooding erosion may alter natural drainage channels
• Societal and community impacts
• Psychological impacts of impacted populations
• Disruptions to education delivery to community

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

Sacramento County is determined have considerable portions of the county to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Sacramento County has a long-documented history of large-scale flood events. Floods can occur at any time but are most common in the Sacramento region with winter storms that are saturated with subtropical moisture.

The area surrounding the CSU Sacramento campus is an urban residential environment. The campus borders the American River which drains the 1,900 square mile American River Watershed. Levees are in place to protect the campus from the river. The campus is located in an area classified as Zone X Special Flood Hazard Area (Area with Reduced Flood Risk Due to Levee). The river channel opposite of the levee is zoned as Zone AE Special Flood Hazard Area (Area Inundated by 1% Annual Chance of Flooding) and has a history of flood events. Access in and out of the campus may become compromised in flooding events on or off campus. There are specific buildings and areas of the campus that are low lying and have a greater risk for isolated flooding. As the area is also subject to isolated urban or street flood events, this provides a further demonstration of potential flood activity.

The probability of future occurrence for flooding is Possible.

Vulnerability to the Hazard

The CSU Sacramento campus is subject to the effects of isolated flooding resulting primarily from excessive precipitation and isolated strong storms. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of Sacramento due to overflow or damage to flood control systems. The flood control channels, levees and drainage systems that surround the campus have
limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the CSU Sacramento campus will vary depending on when the flood was to occur and the location of any people and/or assets located in low lying areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community may become trapped on campus depending on the level of flooding occurring on surface streets. However, in region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

CSU Sacramento is in proximity to a variety of industrial and commercial facilities in the surrounding communities. When these facilities are inundated with flood water, the potential for chemical release exists presenting possible exposures to individuals from the campus community. These facilities additionally line many of the primary access routes in and out of the campus.

During low probability, severe flood evenbts, some campus buildings and infrastructure would be vulnerable to large-scale flooding if it reaches the university. Campus utilities and communication capabilities might be impacted by flood waters rendering them disabled. A flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. Flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation located in isolated low lying areas of the campus.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year,
the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

The maximum total replacement costs due to flood are unknown, as estimated campus facility and structure costs were not available for CSU Sacramento.

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods.

The proximity to the American and Sacramento River presents an additional flood hazard for the campus.

The potential for flooding generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has
exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls located in low lying areas.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Hazardous Materials**

**Description of the Hazard**

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.)

---

possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from *Natechs* or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. The planning committee indicates that chemicals are located in science labs on campus, and that hazardous materials are transported by rail very close to the campus. Hazmat waste sites are also located near campus. At larger scales (beyond the campus planning area) hazardous materials and

---

infrastructure are located throughout the city and county of Sacramento, and reflect different types, configurations and scales dispersed across these geographic areas.

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

However, for the CSU – Sacramento planning committee, although chemicals are well managed in campus science labs, and no events have taken place on campus, trains transporting chemicals close to the campus (including two derailments to date) increase the extent of the hazard risk. In addition, gas pipelines and hazardous waste sites are located close to the campus. Based on these factors, it is prudent to rank the extent of the hazard for the CSU – Sacramento campus as Moderate, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

---

According to the campus planning committee, two train derailments took place very close to the campus in approximately 2011/2012 and 2015/2016. No events have taken place since that time.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – Sacramento campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

Potential Impacts of the Hazard (Natechs)

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Sacramento) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the CSU – Sacramento campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low to Moderate - the campus has not experienced a hazmat event on campus, but 2 train derailments took place near the campus. As such, the risk of occurrence on or near campus is beyond campus control and is multiplied. In addition, nearby hazardous materials and infrastructure further increase vulnerability and probability of a campus-related event. Moreover, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the CSU – Sacramento campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: chemicals are present in science and research labs. In addition, a rail line transporting chemicals runs along the western and southern borders of campus and several hazardous waste sites are very close to the campus footprint. Gases and
chemicals or hazardous waste, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Sacramento leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Sacramento) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Sacramento County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Sacramento campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and

Identified Data Limitations

The CSU – Sacramento planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

*Landslide*

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

---

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within the deposition zone and can result in downstream flooding. Post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 18-14. Based on Figure 18-14 (below), the CSU Sacramento campus is located in an area with a very low degree of susceptibility to landslide.

Figure 18-15: Deep-seated Landslide Susceptibility Surrounding CSU Sacramento

Based on the Figure below, the CSU-Sacramento campus is not located in or near any landslide susceptibility zones.

---

Extent of the Hazard

The extent of landslide hazards in Sacramento County is limited to a small strip along the eastern boundary; landslides are not likely to occur in Sacramento. However, the indirect impacts of landslides in the region may cover a larger geographical extent. Based on the campus’ location distant from any landslide zones, and no history of occurrences on or near the campus, the planning committee ranks the extent of the hazard as **Low**.

History of the Hazard

FEMA has declared seven major disasters in Sacramento County involving landslides, mudslides, or mud flows since 1983. The campus has no history of landslides.

Potential Impacts of the Hazard

CSU Sacramento may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.
Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels.\textsuperscript{12} Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

**Probability of Future Occurrence of the Hazard**

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred rarely in Sacramento and therefore are not likely to occur in the future. Based on these factors, and the location of the campus far away from landslide zones, the probability of future occurrence is **Unlikely**.

**Vulnerability to the Hazard**

The severity and magnitude of future landslides is negligible in Sacramento. The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. That said, the CSU Sacramento campus exhibits very few, if any building and infrastructure vulnerabilities due to its location; therefore, its landslide vulnerability is limited to secondary effects of a landslide such as a power outage or transportation disruption. **Estimate of Potential Losses**

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Sacramento.

**Vulnerability Assessment Conclusions**

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides are not likely to impact the campus, though indirect impacts to campus transportation and utilities are possible. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may
impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the CSU Sacramento campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.

Power Outage

Description of the Hazard

Sacramento is the capital city of the state of California. It is also the seat and largest city of Sacramento County. It is also the home of CSU Sacramento (Sacramento State).

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly populated areas like Sacramento without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the Sacramento State University campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of Sacramento State student residents in on-campus housing would also be affected by a power outage on campus and in the area.

Additionally, a severe outage to Sacramento would directly affect the campus and the community.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions are:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, as a hazard, it has the potential to occur and affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.
Rotating blackouts become a possibility when Stage 3 is reached.

A power outage could affect the entire area of the campus, including the Sacramento State athletic fields, classrooms resident halls, administrative offices, virtual, telephonic and radio communications, leading to loss of lighting in campus parking structures, and creating a cascading hazard for commuters as they depart from or arrive to campus in the evening. Additionally, the university is located within proximity of highly utilized thoroughfares for the transportation of goods to throughout California, within one of the busiest areas of the Silicon Valley.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. However, given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard

Sacramento State did not report experiencing any power outages due to PSPS but has experienced outages due to mechanical failure, human error, accidents, and other utility provider related power outages. Sacramento State did not report any power outages in the recent years at Sacramento State but did advise that the university is expanding their mitigation efforts by replacing sub-stations and upgrading outdated systems that may potentially exacerbate the probability of a power outage.

Potential Impacts of the Hazard

Instructors, campus residents, staff, and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.
With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

Probability of Future Occurrence of the Hazard

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City of Sacramento and Sacramento County experience such outages. As such, the probability ranking for the Sacramento area is Likely. Since the CSU Sacramento campus has also recorded power outage events, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

Vulnerability to the Hazard

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

Estimate of Potential Losses

The data provided by Sacramento State does not report any value for potential losses due to power outage.

Vulnerability Assessment Conclusions

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Sacramento State. Vulnerable
populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

Sacramento State did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.

**Volcano (Associated Air Quality)**

**Description of the Hazard**

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

**Location of the Hazard**

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long

---

Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU Sacramento or Sacramento County is located within a volcano hazard zone.

**Extent of the Hazard**

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While CSU Sacramento does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

**History of the Hazard**

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California.\(^{11}\) The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.\(^ {12}\)

**Potential Impacts of the Hazard**

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Sacramento is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Sacramento.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
• Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Sacramento, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

CSU Sacramento is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

Wildfire

Description of the Hazard
While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- Topography – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.
- Weather – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire

---

78 State of California Hazard Mitigation Plan, September 2018
behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. Sacramento is located in the heart of the Sacramento Valley between the southern Sierra Nevada Mountains and Coastal Ranges. In general, areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur 12 miles to the east and 32 miles to the west of Sacramento. These areas surrounding the valley are topographically diverse, contain heavier vegetative fuels, and often have residential development interspersed. The land in the Sacramento Valley where the CSU Sacramento campus is located, is largely urban, suburban, or otherwise developed and lies a long distance from any fire hazard severity zones.

The CSU Sacramento campus is located in the eastern portion of the City of Sacramento. The area immediately surrounding the campus is predominately developed with residential and commercial land uses. The American River Parkway is immediately adjacent to the campus containing light to moderate fuels but is narrow and contains a line of trees and brush along the river-bed immediately next to the campus. Extensive agricultural and open fields exist surrounding the city. The campus is located 4 miles east of downtown Sacramento. High Fire Hazard Severity Zones are found along the length of the foothills to the Sierra Nevada Mountains and Coastal Ranges.

However, the CSU Sacramento campus is located in the Central Valley surrounded by the mountains and extensive areas of fire hazards. These mountain ranges host three national forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the valley in the right weather conditions. The geography of the Central Valley creates a topography that captures air pollutants including smoke within the surrounding mountains and the development of inversion layers. The CSU Sacramento campus is located in a region in
which is vulnerable to wildfire smoke that can saturate the air around the campus even from substantial distances.

Figure 18-16: Fire Hazard Severity Zones, Sacramento, CA

Extent of the Hazard

The area immediately surrounding the CSU Sacramento campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. Based on the above factors, the planning committee ranks the extent of the hazard for the campus as **Low to Moderate**.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future

---

or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 18-25: National Fire Danger Rating System⁸⁰

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>

</tr>
<tr>
<td>CLASS 4:</td>
<td>Fires start very easily and spread at a very fast rate</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity</td>
</tr>
<tr>
<td>Very High Danger (VH)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>COLOR CODE: Orange</th>
<th>characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 5: Extreme (E) COLOR CODE: Red</td>
<td>Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</td>
</tr>
</tbody>
</table>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.

Figure 18-17: Air Quality Index for Ozone and Particulate Pollution

---

History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. The Sacramento Region also has a long history of wildfire activity primarily in the foothills and open rangelands. Wildfires occurring in the Sacramento Region have resulted in thousands of acres burned and substantial damages.

CSU Sacramento does not have a history of wildfire activity occurring within proximity to the campus. However, the campus has experienced multiple days of poor air quality due to fires burning in throughout northern California. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Sacramento. CSU Sacramento personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

83 Sacramento County Local Hazard Mitigation Plan, October 2016
Potential Impacts of the Hazard

The location of the CSU Sacramento campus surrounded by areas of urban development removed from areas with a fire hazard places a minimal direct threat from wildfire to the campus. The potential impacts to wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets
- Air conditioning systems overwhelmed
• Greater demands on air filtration systems
• Greater demands on healthcare systems
• Reduced outdoor work productivity
• Closures of academic session

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Residential communities along the Wildland Urban Interface may experience extensive damage or destruction in areas the campus community members call home. Utilities feeding areas of Sacramento County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, research, scenic value, and wildlife that are a part of the culture of the campus community.

Probability of Future Occurrence of the Hazard

Based on the wildfire threat potential in the area surrounding the CSU Sacramento campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered Unlikely.

Based on the wildfire threat potential in the area surrounding the Sacramento region, including the volume of areas in elevated Fire Hazard Severity Zones surrounding the Sacramento Valley, the probability of wildfire generated smoke impacts to air quality is considered Possible.

Vulnerability to the Hazard

The CSU Sacramento campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban area of Sacramento. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of Sacramento. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people or the generation of smoke. These effects may spill onto the campus.

Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Fires along the American River Parkway have potential to present fire exposure to the campus but limited potential to produce conditions that would allow for fire spread onto the campus. Smaller vegetation fires are remotely possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than
older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

Some areas of particular vulnerability on the campus includes:

- Students and staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC or do not have HVAC will cause limitations in filtering of air during smoke filled days.
- Power outages or brownouts during days with high levels of smoke will limit shelter in place options during heat events in summer.

The greater concerns regarding vulnerabilities to wildfire on CSU Sacramento are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Sacramento Valley even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Sacramento students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU Sacramento campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows,
and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

The maximum total replacement costs due to wildfire are unknown, as estimated campus facility and structure costs were not available for CSU Sacramento.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Sacramento County; however, wildfire incidents do not pose a direct risk to the CSU Sacramento campus. The location of the CSU Sacramento campus surrounded by densely developed residential, commercial, and industrial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities. Any direct threat posed by wildfire would likely be generated via the American River Parkway, however the parkway proximal to the campus is lacking dense vegetation.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The students, faculty, and staff of CSU Sacramento who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the campus. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.

Additionally, the topography of northern California surrounded by mountains allows for smoke filled air to linger in the Sacramento Valley with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains generating tremendous quantities of smoke present tremendous health related vulnerabilities to
members of the campus community. The campus community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, Lightning)**

**Description of the Hazard**

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods

---

ranging from about three (3) to seven (7) years, the surface waters across a large swath of
the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to
normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle,
directly affects rainfall distribution in the tropics and can have a strong influence on
weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring
between them called the Neutral phase. The El Niño phase is characterized by unusually
warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific,
while the La Niña phase is characterized by unusually cold ocean temperatures and
stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases
lead to significant differences from the average ocean temperatures, winds, surface
pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that
conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across
the world, including in California. On average, areas across California experience
exceptionally stormy winters with increased precipitation under El Niño conditions, but
experience less stormy and drier winters under La Niña conditions. This variability in
storminess and precipitation brought on by El Niño and La Niña events affects the both
the frequency and intensity of severe weather conditions experienced by all CSU
campuses, including CSU Sacramento.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer
Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected
north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation
over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As
a result, most summer storms are generated due to the incursion of moist air from the
Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in
the desert and mountain regions of the state. In the winter months, the Pacific High
decreases in intensity and moves south, permitting powerful Pacific storms to move into
and across the state; these storms can produce extreme winds, heavy rains (including

---

88 Retrieved on 07.17.2021 from https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions
89 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
“atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.91

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU Sacramento), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.92

**Types of Storms in California**

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.93 The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.94 These storms affect (in varying degrees) all CSU campuses, including CSU Sacramento.

- **Thunderstorm:** A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.95 Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.96 Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.97

The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\(^98\)\(^99\)

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.\(^100\)
- **Wind storm**: marked by high wind with little or no precipitation.\(^101\)
- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\(^102\)
- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.\(^103\)
- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\(^104\)
- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially

\(^{98}\) Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

\(^{99}\) Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm

ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\textsuperscript{105}

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\textsuperscript{106} Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”\textsuperscript{107}

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU Sacramento).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any

\textsuperscript{107} Retrieved on 07.15.2021 from https://forecast.weather.gov/glossary.php?word=wind%20gust
duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\textsuperscript{108}

**Strong Winds**

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\textsuperscript{109}

**Thunderstorm Winds**

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\textsuperscript{110}

Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\textsuperscript{111} However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

**Tornadoes**

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\textsuperscript{112} This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\textsuperscript{113} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{114}

**Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.**

**Santa Ana Winds.** A type of wind hazard that is peculiar to Southern California is called a **Santa Ana Wind.** Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern

\textsuperscript{111} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/

Baja California (Mexico). They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape. (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

---

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.\textsuperscript{118}

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining

\textsuperscript{117} Retrieved on 07.14.2021 from https://twitter.com/nwslosangeles/status/933049473034579968

\textsuperscript{118} Retrieved on 07.13.2021 from https://www.fireweather.org/diablo-winds
narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.119 120 121

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.122 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.123

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.124

---

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{125} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including at the CSU Sacramento main campus and at off-campus facilities owned by the school. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all CSU Sacramento campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU Sacramento reflect those of the surrounding community and County. As a result, all assets and people at CSU Sacramento are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Sacramento area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MILD**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.\textsuperscript{126} First developed in 1805, it is still used today to estimate wind strengths.\textsuperscript{127}

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^\text{129}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 18-29: Fujita Tornado Scale (Pre-February 2007)\(^\text{130}\)

<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as LOW.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms.\textsuperscript{134}  \textsuperscript{135} That said, according to the \textit{Glossary of Meteorology} published by the American Meteorological Society (AMS), a thunderstorm is reported as \textit{light, medium, or heavy} according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\textsuperscript{136}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- \textbf{Airmass Thunderstorm}: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{137}
- \textbf{Frontal Thunderstorm}: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{138} or
- \textbf{Squall-line Thunderstorm}: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\textsuperscript{139}  \textsuperscript{140}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as \textbf{LOW}.

\textsuperscript{134} Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
\textsuperscript{135} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
History of the Hazard

Severe weather hazards have been an annual occurrence in Sacramento County and on the CSU Sacramento campus. Historical data for these hazards are presented below.

Historical Storm Data Collection: NCEI Storm Events Database

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.¹⁴¹ For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.¹⁴² To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Sacramento County since 1996.¹⁴³ Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.¹⁴⁴

- **High Wind:** at least 42 events, or approximately 1.66 events per year¹⁴⁵

¹⁴³ National Climatic Data Center. Storm Events Database. ¹⁴⁵ Retrieved on 07.19.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&beginDate_mm=01
• **Strong Wind**: at least 30 events, or 1.18 events per year

• **Thunderstorm Wind**: at least 9 events, or approximately 0.36 events per year

• **All Wind Hazard events** (excluding Tornadoes): at least 75 events, or approximately 2.96 events per year. (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Sacramento County, there have been at least 75 wind hazard events since 1996, excluding tornadoes. That translates to an approximate average historical frequency of occurrence of 2.96 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 81 events) and simultaneous Database searches of all severe weather hazard events (i.e., 75 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Sacramento County have actually taken place hundreds of

miles away, but are erroneously recorded as events that have occurred in the County. When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 75 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Sacramento County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Sacramento County has experienced since 1996 have been costly. There have been 3 deaths and 2 injuries, and property and crop damage estimates have totaled approximately $12,988,000 and $39,000, respectively.151

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 10 reported events of tornadoes in Sacramento County, which translates to approximately 0.39 tornado events per year.152

The vast majority of tornado reports in Sacramento County since 1996 have been of tornadoes with a severity rating of F0/EF0. Only one (1) of the tornadoes reported in has been rated F1/EF1 or higher (it was an EF1 tornado that occurred in 2012); that translates to approximately 0.04 events of F1/EF1 tornadoes have occurred per year in Sacramento County.153

**Historical Tornado Hazard Losses for Sacramento County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Sacramento County has experienced since 1996 have been costly. While there have been

no deaths, injuries, or crop damage, property damage estimates have totaled approximately $730,000.\textsuperscript{154} (Note: The one (1) F1/EF1 tornado that occurred in Sacramento County in 2012 caused no deaths, injuries, property losses, or crop losses.)

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 8 reported events of hail in Sacramento County, which translates to approximately 0.32 hail events per year.\textsuperscript{155} (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of nine (9) reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Sacramento County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Sacramento County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Sacramento County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damages reported, property damage estimates have totaled approximately $111,030.\textsuperscript{156} (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Sacramento County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there has been one (1) reported event of lightning in Sacramento County, which translates to approximately 0.04 lightning events per year.\textsuperscript{157}
**Historical Lightning Hazard Losses for Sacramento County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Sacramento County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damages reported, property damage estimates have totaled approximately $150,000.158

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

Information obtained from the NCEI Storm Events Database indicates that there have been 94 occurrences of the severe weather hazard in Sacramento County. This translates to 3.71 severe weather hazard occurrences per year.159

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 101 events) and simultaneous Database searches of all severe weather hazard events (i.e., 94 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Sacramento County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.160 When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 94 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Sacramento County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Sacramento County has experienced since 1996 have been costly. There have been 3

159 Retrieved on 07.19.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Hail&eventType=%28Z%29+High+Wind&eventType=%28C%29+Lightning&eventType=%28Z%29+Strong+Wind&eventType=%28C%29+Thunderstorm+Wind&eventType=%28C%29+Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SACRAMENTO%3A67&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA

deaths and 2 injuries, and property and crop damage estimates have totaled approximately $13,979,000 and $39,000, respectively.\textsuperscript{161} It is important to note that for all Sacramento County severe weather hazard events recorded on the Storm Events Database, 100\% of all deaths, injuries, and crop losses, and approximately 93\% of all property losses, have been caused by wind hazard events alone.

Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April.\textsuperscript{162} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textbf{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6 days accounting for 90\% of all occurrences. The remaining 10\% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{163} \textsuperscript{164}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

\textsuperscript{161} Retrieved on 07.19.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Hail&eventType=%28Z%29+HighWind&eventType=%28C%29+Lightning&eventType=%28Z%29+StrongWind&eventType=%28C%29+Thunderstorm+Wind&eventType=%28C%29+Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SACRAMENTO%3A67&hailfilter=0.00&tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SACRAMENTO%3A67&hailfilter=0.00&to

**Diablo Winds**

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^{167}\)

---

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{168}

Figure 18-20: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\textsuperscript{169}

\textbf{Sundowner Winds}

Strong sundowner wind events occur approximately \textbf{2-3 times per year.} These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\textsuperscript{170}

* Note: The Santa Ana and Sundowner wind hazards are not present in Sacramento County. They are included here for information purposes only.

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within CSU Sacramento campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU
Sacramento campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus. According to the 2016 Sacramento Countywide LHMP, wind hazards (including tornadoes) are considered to be low significance, and therefore to have a minimal potential impact on the County and (by extension) CSU Sacramento.171

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed. According to the 2016 Sacramento Countywide LHMP, hail hazards are considered to be of medium significance, and therefore have a moderate potential impact on the County and (by extension) CSU Sacramento.172

**Lightning**

Lightning strikes the United States about 20-25 million times a year.173 Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.174 Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.175 (Commercial claim payouts for lightning losses for the U.S. were not available.)

175 Retrieved on 07.21.2021 from https://www.iii.org/table-archive/20504
According to the 2016 Sacramento Countywide LHMP, lightning hazards are considered to be of medium significance, and therefore have a moderate potential impact on the County and (by extension) CSU Sacramento.\textsuperscript{176}

### Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The 2016 Sacramento Countywide Local Hazard Mitigation Plan (LHMP) states that there is a near 100\% chance that each of the severe weather hazards profiled above for Sacramento County (i.e., wind, tornado, hail and lightning) will occur in the future.\textsuperscript{177} Also, according to the NCEI Storm Events Database, some of these same severe weather hazards have occurred in Sacramento County at least once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Sacramento campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU Sacramento campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the Sacramento Countywide LHMP and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU Sacramento campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU Sacramento is \textbf{HIGHLY LIKELY}. See Table below for probabilities of future occurrence for component severe weather hazards for the county and the campus.

Table 18-34: Severe Weather Hazard Probabilities of Future Occurrence for Sacramento County and CSU Sacramento.

<table>
<thead>
<tr>
<th>Severe Weather Hazard Category</th>
<th>Average Number of Hazard Events Per Year</th>
<th>Probability of Future Occurrence</th>
</tr>
</thead>
</table>

Vulnerability to the Hazard

People, structures, and assets on CSU Sacramento campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The CSU Sacramento campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire CSU Sacramento campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within the CSU Sacramento campus are at risk from severe weather. There are approximately 64 buildings on the main campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. Unfortunately, the total replacement costs due to severe weather hazard are unknown, as estimated campus facility and structure values for CSU Sacramento were not available. Moreover, an analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.
The population at the CSU Sacramento campus varies throughout the day. As of Fall, 2019, CSU Sacramento had 31,156 students and 3,228 faculty and staff. All are at risk from severe weather events, with 34,384 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to the CSU Sacramento campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU Sacramento.

It is evident that the CSU Sacramento campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.

18.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionally more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Sacramento campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
Table 18-35: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
</table>
| Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning? | Foreign language speakers
|                                                                         | Commuter students                                    |
| Which population groups are most difficult to reach in an event?         | Deaf employees (deaf studies professors)              |
| Which population groups have little/limited support networks if impacted by an event? | DACA students                                        |

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**
In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- The most difficult to reach in an event are deaf studies professors whose offices have doorbells with lights. (Campus has a high of hearing-impaired population.)
- Those who have little support networks if impacted by an event are the Dreamers (DACA students) living off campus as a result of immigrations issues with their parents.
- High concern with the portion of students who are homeless and living out of their vehicles; they have no resources for them.
- Concern with evacuation due to fire because a lot of buildings are older and do not have evacuation chairs in stairwells.
- The new parking structure #5 was retrofitted with WIFI repeaters at all locations so students without internet at home can work from their cars.
- No issues with immigration status because they have incorporated information into the EOP

**Campus High Hazards and Potentially Vulnerable Populations**

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on
subsistence fishing for their livelihoods.\textsuperscript{180} Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\textsuperscript{181} Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

\textit{Earthquake}

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing

for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.\textsuperscript{182}

\textit{Erosion}

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

\textit{Extreme Temps}

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

\textit{Heat}

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and

inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 183

**Flood**

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such

as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. ¹⁸⁴

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural health and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, anger, sadness and grief. ¹⁸⁵ Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

**Hazardous Materials**

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or

evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease. Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.

**Power Outage/Public Safety Power Shutoffs (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And,

---

186 https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/

in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision

making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

19.1 University Profile

University History

California State University, San Bernardino (CSU San Bernardino) was founded in 1960 as San Bernardino-Riverside State College. The school earned its university status in 1984, officially becoming CSU San Bernardino. Today, the school includes five colleges and is classed as a Master's College and University by the Carnegie Institute. It is a federally recognized Hispanic-Serving Institution and was selected by the Carnegie Foundation for Distinctive Community Engagement. In 2020, the National Security Agency chose CSU San Bernardino to help lead its cybersecurity workforce development initiative and named the school’s Cybersecurity Center as the Community National Center for Cybersecurity Education.

CSU San Bernardino is designated as a Hispanic-Serving Institution (HSI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The Faculty Senate of CSU San Bernardino includes elected faculty representing each of the five colleges, as well as a voting counselor, librarian, lecturer, and student representatives. The president and provost are active ex-officio members of the Senate. The Senate includes over 50 standing, special, college, and department committees. Meanwhile, both the Staff Council and Associated Students, Incorporated are made up of representatives who participate in shared governance.

CSU San Bernardino is developing a Shared Governance Steering Committee, which will include representatives of the Associated Students, Faculty Senate, Staff Council, and the Administration. The future goals of this Committee will be to create partnerships with the community, integrate input from all stakeholders, and share accountability. The school is in the process of finalizing the CSUSCB Statement on Shared Governance.

University Mission

"Create a dynamic learning environment through premiere programs and services that promote student success, enhance the learning experience, and engage students intentionally with communities”.

In support of this mission, CSU San Bernardino has a vision to advance communities and regions by connecting them with students focused on social justice and integrity. The
Core values driving these goals center around social justice, sustainability, inclusivity, and transparency.

University Location

The 441-acre CSU San Bernardino campus is located in northern San Bernardino, framed by the San Bernardino Mountains. San Bernardino, a city of approximately 215,000, is located between the Cajon and San Gorgonio passes, positioning it as an intermodal logistics hub. The city is located approximately 60 miles east of Los Angeles and 60 miles northeast of the Pacific Ocean.

University Population

CSU San Bernardino typically enrolls approximately 20,000 students per semester. In fall 2020, the 19,404-student population was overwhelmingly made up of undergraduate degree seekers with an average age of 22. Hispanic students made up 66% of all students, with White students making up the second most populous group at 12%. 81% all students are first-generation, and 58% are considered low-income. The student population is also overwhelmingly female.

In addition to the student population, the University is home to approximately 950 faculty and staff.

19.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities
located in the identified hazard area.

**Requirement §201.6(c)(2)(ii)(B):** The plan should describe vulnerability in terms of an estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate.

**Requirement §201.6(c)(2)(ii)(C):** The plan should describe vulnerability in terms of providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

**Requirement §201.6(c)(2)(iii):** For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

### 19.3 Hazard Identification and Risk Assessment

**Overview of California State University, San Bernardino History of Hazards**

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

**Hazard Identification**

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s *How-To Series*, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population,
and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 19-1 (following).

Table 19-1: Hazard Identification Determinations

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:
- Highly Likely- 76%-100% that the hazard would occur annually.
- Likely- 50%-75% that the hazard would occur annually.
- Possible- 11%-49% that the hazard would occur each annually.
- Unlikely- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 19-2 below.)

**Descriptions of Identified Communicable Disease Hazards at CSU San Bernardino**

CSU San Bernardino has identified two (2) communicable disease hazards that have had the greatest impact on campus – COVID-19 and Tuberculosis. The following are brief descriptions of the communicable disease hazards at CSU San Bernardino.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.  

**Tuberculosis**

Tuberculosis (TB) is a potentially serious infectious disease that mainly affects the lungs. Tuberculosis is caused by bacteria that spread from person to person through microscopic droplets released into the air. This can happen when someone with the untreated, active form of tuberculosis coughs, speaks, sneezes, spits, laughs or sings.

Although tuberculosis is contagious, it's not easy to catch. It is more likely for someone to get tuberculosis from a close family member or coworker than from a stranger. Most people with active TB who have had appropriate drug treatment for at least two weeks are no longer contagious.

Many strains of tuberculosis resist the drugs most used to treat the disease. People with active tuberculosis must take several types of medications for many months to eradicate the infection and prevent development of antibiotic resistance. 

---

Location of the Hazard

Communicable diseases have the potential to affect the entire CSU San Bernardino (CSUSB) planning area equally. As a result, the communicable disease hazard can be found both at the CSU San Bernardino (CSUSB) main campus located in San Bernardino, CA (San Bernardino County), and at the CSUSB satellite campus in Palm Desert, CA (Riverside County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) both CSUSB locations are at risk of exposure to the communicable disease hazard.

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For CSU San Bernardino, approximately 8% of its 20,311 enrolled students (or 1,625 students) reside in student housing.  

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 19-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

---

8 California State University. CSU Campus Match. Retrieved 04.30.2021 from: https://www2.calstate.edu/attend/campuses/campus-match/Pages/campus-match.aspx
The Extent of CSU San Bernardino Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Tuberculosis at CSU San Bernardino. Tuberculosis would be classified at either the BSL-2 or BSL-3 containment level.  

The Extent of CSU San Bernardino COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3. 

History of the Hazard

Most communicable disease data are maintained by at the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

---

Table 19-5 shows county-level COVID-19 case data for San Bernardino County and Riverside County. County case data are updated on at least a weekly basis. No campus-level COVID-19 case data could be found for CSU Bernardino. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including CSU – San Bernardino. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU San Bernardino students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic, and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU San Bernardino) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.). \(^{13}\)

Table 19-5: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 19-7 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 19-6: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG I</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one’s hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>

</tbody>
</table>

These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

### RG 4

<table>
<thead>
<tr>
<th>H5N1 (Bird Flu)</th>
<th>Dengue Hemorrhagic Fever</th>
</tr>
</thead>
<tbody>
<tr>
<td>Marburg Virus</td>
<td>Ebola Virus</td>
</tr>
<tr>
<td>Smallpox</td>
<td>Lassa Fever</td>
</tr>
<tr>
<td>Crimean-Congo Hemorrhagic Fever</td>
<td>Other Hemorrhagic Diseases</td>
</tr>
</tbody>
</table>

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are *not* available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

### Probability of Future Occurrence of the Hazard

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency. Table 19-8 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:
Table 19-7: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence. Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the CSU San Bernardino campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, the CSU- San Bernardino had 20,311 students and additional faculty and staff.) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic on the CSU San Bernardino campus.

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU San Bernardino) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high

negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 19-2 below for the economic impact to the campus). Several CSU campuses saw refund losses surpass $10 million. (See Figure 19-2.)

**Mitigative Relief from Federal Assistance**

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 19-10.) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems. Table 19-11 shows the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

See Table 19-11 below for the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system, including CSU San Bernardino. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.
Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

Dam and Levee Failure

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting

communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from over toppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

San Bernardino County is home to a variety of flood control facilities and levee systems mostly along the base of the various mountains and hills throughout the county. Levees have been constructed along flood control channels providing community protection, primarily along the Santa Ana River at the base of the San Bernardino Mountains. The CSU San Bernardino campus immediately adjacent to the dam and levee system at Devils Canyon.
There are a number of dam facilities along the base of the San Bernardino Mountains. The Devils Canyon Dike #1 Dam is immediately adjacent to the campus on the northwest side. The reservoir is not normally full and is made available to capture runoff from the Devils Canyon section of the San Bernardino Mountains. The CSU San Bernardino campus lies outside of dam inundation zones for this facility but major transportation routes south of the campus are within the inundation zone including Kendall Drive and University Parkway. The larger facilities include the Seven Oaks Dam located in San Bernardino County east of Highland on the Santa Ana River. This is a large reservoir with the potential holding capacity of 145,600-acre feet of water when full, however this lake is not normally a storage facility that routinely holds water instead used for flood control when needed. The Seven Oaks Dam does not have a direct impact on the campus but would affect the community supporting the campus.

Figure 19-4: Devils Canyon Dike #1 Dam Breach Inundation Map

---

26 California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
Devils Canyon drains the eastern portion of the San Bernardino Mountains south of Crestline and Cedar Pines Park. The California Aqueduct additionally feeds into southern California near this location. There are a series of levees that extend from the dam facility that line the reservoir and extend around the northwestern corner of the campus. The levee forms the western and northern borders of the campus. The campus is located within a levee protected zone for Devils Canyon.
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

<td>Devils Canyon Dike #1</td>
<td>79af</td>
<td>High Hazard</td>
</tr>
</tbody>
</table>

The CSU San Bernardino campus lies outside of the inundation zone of the Devils Canyon Dike #1 Dam. However, the campus borders the reservoir facility. In the event of a catastrophic failure of the Devils Canyon Dike #1 Dam, the CSU San Bernardino campus is expected to remain out of the inundation area. The inundation area is expected to spread water down the discharge channel onto Kendall Dr and University Parkway, two of the primary access routes to the campus. These transportation corridors that lie within the dam inundation zone would compromise access to and from the campus affecting the ability to evacuate, gain access to emergency services, and receive supplies. The roadways expected to become inundated in a dam breach scenario would limit access to Interstate-215. Based on the above factors, the planning committee ranks the extent of the hazard as **Moderate**.

**Extent – Levee Failure**

Levees are used to contain potential water releases from the Devils Canyon Basins immediately adjacent to the campus. The CSU San Bernardino campus lies within the levee flood protected area. In the event any of these basins were filled at elevated levels and a failure of a levee were to occur, the community surrounding the campus would likely experience flood related damages. This specific hazard could alter the ability of the campus to maintain operations as damages would be extensive. Depending on the location of a breach, the campus community would be heavily affected with the loss of life and homes, access to campus would be limited, and student financial capacity to support ongoing education being diminished. Based on the above factors, the planning committee ranks the extent of the hazard as **Moderate**.

**History of the Hazard**

There are no records of dam or levee failures in areas that present a threat to the CSU San Bernardino campus. Additionally, there have been no occurrences of dam or levee

---

failure threatening the Palm Desert Campus in Riverside County. San Bernardino County has not experienced dam or levee failures elsewhere in the County:

Potential Impacts of the Hazard

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

Levee Failure Impacts – A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

**Probability of Future Occurrence of the Hazard**

San Bernardino County is determined to be at risk from dam and levee failure in various locations of the county. The location of the CSU San Bernardino campus in proximity to the Devils Canyon Dike (dam) demonstrates that the potential exists for future dam related issues. Portions of the neighborhoods surrounding the campus are within the dam inundation zone for the Devils Canyon Dike but flows towards the south and away from the campus. Access routes to and from the campus would be impacted by a collapse of this facility. The campus is bordered by the Devils Creek diversion levees along the west and northwest borders of the campus. The campus lies entirely within the levee protection zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on historical experience and occurrences, the likelihood of this hazard is low.

The CSU San Bernardino, Palm Desert campus is not within proximity to any dams nor within any dam inundation zone. There are no identified levees in proximity to the Palm Desert campus and thus the campus is outside of any levee protected zone. The probability of future occurrence for both dam and levee failures is **Unlikely**.

**Vulnerability to the Hazard**

The CSU San Bernardino campus is subject to the potential effects of flooding resulting from compromised dams and levees. The effects of dam failure would likely be indirect affecting members of the campus community and regional transportation networks and services. Some flood control channels are lined by levees intended to protect the surrounding areas from rises in water level. In the case of dam failure, the amount of time to respond to the needs of the campus community prior to inundation will be limited.

The most significant challenge regarding dam failures is they generally result in catastrophic outcomes. Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.
The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of flood insurance will cause extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the CSU San Bernardino campus will vary depending on when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $626,694,141. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU San Bernardino.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the CSU San Bernardino campuses, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. The consequences of a dam failure would generate catastrophic results to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to
the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.
**Drought**

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
• **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU San Bernardino) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified throughout San Bernardino County and the city of San Bernardino where the campus is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to the campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously in the state, with 80-100% of the state impacted for 12 of the last 20 years. ²⁸

**Extent of the Hazard**

Although drought impacts have not been reported specifically for the campus, given the historical occurrence of severe drought impacts throughout the city and county surrounding the planning area and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk to the state, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. That said, although drought affects the entire CSU 23 campus planning area, the potential impacts are variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities that shape drought vulnerability within each jurisdiction; currently, the extent of drought on campus is evaluated by the committee to be minimal.

In addition, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Though such effects have not been reported on campus, they remain issues of concern for the campus in the long term.

Although the campus planning team identifies the extent of the hazard as Low (qualitatively) which corresponds to D0 – D1 on the Extent scale (below), San Bernardino County has experienced more severe drought conditions for 15 of the past 20 years, including 5 years of D4 levels. As such, the campus planning team recognizes that while historic impacts shaping the extent of drought on campus have been minimal, the potential impacts are tied to trends across larger geographic areas, and, therefore, the committee recognizes that the extent of drought on campus has the potential to increase in the future.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

</tbody>
</table>
History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous. According to the US Drought Monitor, Time Series data, San Bernardino County has experienced 7 periods of drought between 2000 and 2021 including a severe drought event from 2011 – 2019 that impacted the entire county encompassing the CSU - San Bernardino footprint.

Figure 19-6: Periods of Drought in San Bernardino County, California, 2000 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

Source: https://droughtreporter.unl.edu/advancedsearch.aspx
Source: https://www.ncdc.noaa.gov/stormevents

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the

---

region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions has been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 19-7: Periods of Drought in San Luis Obispo County, California, 2000 – 2021

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the county surrounding the CSU - San Bernardino campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal’. The report calls the

groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent. 33

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

Though no impacts have been recorded on campus, the most significant potential impact associated with drought across the CSU - San Bernardino campus planning area a potential reduction in water availability for the municipal area tied to each campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - San Bernardino to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of any agricultural research crops and/or field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. 34 However, the wildfire hazard is analyzed separately in this plan. (See Wildfire section below).

In reviewing the occurrences of drought for San Bernardino (city and county), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - San Bernardino, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle)

further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area. 35

At present, drought related damage to campus buildings and infrastructure at CSU - San Bernardino has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - San Bernardino is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - San Bernardino. A reduction of electric power generation and water quality deterioration are also potential impact factors.

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence in the state in any given year. Given that CSU - San Bernardino lies within a frequently drought-impacted county and region (according to Time Series data), it is prudent to extend this Highly Likely probability of occurrence to the planning area even though historic occurrence and impacts are reported to be minimal.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - San Bernardino campus.
Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - San Bernardino planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

Vulnerability of Populations

Drought vulnerabilities for California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerability measures apply to the students, faculty and staff of the CSU – San Bernardino campus.

Property Vulnerability

---

Drought vulnerabilities for property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerability measures apply to the properties of the CSU - San Bernardino campus.

**Natural Environment Vulnerability**

Drought vulnerabilities for the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

With regard to the campus, currently, the primary vulnerabilities are drought impacted trees and landscaping (flora). And, the core issue shaping drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for CSU - San Bernardino’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of San Bernardino and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are
already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.

---

**Earthquake**

**Description of the Hazard**

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by
rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU San Bernardino is located in the northern portions of the San Bernardino Valley. In general, fault systems surround and traverse through San Bernardino and Riverside Counties including the area of CSU San Bernardino. Throughout the basin the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

The Pacific Plate and the North American Plate come together at the San Andreas Fault ½ mile northeast of the CSU San Bernardino campus. In addition to the San Andreas Fault, San Bernardino County is home to or near additional fault systems with the potential to generate strong ground shaking. The San Jacinto Fault extends from Borrego Springs to Lytle Creek along the eastern edges of San Bernardino 2 ½ miles west of the campus. The Cucamonga Fault is another east to west fault 6-7 miles west of the campus traversing the base of the San Gabriel Mountains. There are numerous additional active faults in the area on all sides of the campus.

The CSU San Bernardino, Palm Desert campus is also in the area of a number of active faults. The San Andreas Fault is 3-4 miles north of the campus extending along the base
of the San Bernardino Mountains and the hills of the Joshua Tree National Park. The San Jacinto Fault is 21 miles west of the campus on the opposite side of the San Jacinto Mountains. The Blue Cut Fault extends east to west through the Joshua Tree National Park 11 miles from the campus.
The CSU San Bernardino campus resides next to areas designated to be liquefaction zones. All campus facilities are located outside of the liquefaction zone or areas where liquefaction zones overlap with areas prone to landslides. The areas designated as being susceptible to liquefaction is the Devils Canyon Flood Basins adjacent to the campus including the dams and levees onsite. Additionally, substantial areas of the community surrounding the campus reside within the liquefaction zones including access routes into and out of the campus. This includes Interstate 10, Interstate 215, State Route 210, State Route 30, Waterman Ave., and the Southern Pacific Railroad. The liquefaction zone generally follows the path of the Cajon Wash, the Santa Ana River, and downtown San Bernardino.

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity, and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is
further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

Table 19-16: Modified Mercalli Intensity Scale

</tr>
</tbody>
</table>
The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 19-9: Earthquake Magnitude and Equivalent Energy Release

Although the CSU San Bernardino campus resides next to areas designated to be liquefaction zones, all campus facilities are located outside of the liquefaction zone. However, the campus is surrounded and traversed by powerful fault systems, and the area has experienced several catastrophic events, including the Northridge event. Given the above factors along with the probability for future impacts, the planning committee ranks the extent of the hazard as **High**.

History of the Hazard

---

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. San Bernardino County also has a long history of earthquake activity. The entire area of the Inland Empire is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The June 28, 1992 Landers and Big Bear Earthquakes struck early in the morning centered in the desert and mountains of San Bernardino County 50 and 30 miles east of CSU San Bernardino. The Landers epicenter was in a sparsely populated area but was felt from Los Angeles to areas in Nevada, Arizona, and Idaho. The earthquake ruptured five different faults. Significant ground ruptures were developed displacing the ground up to 6 feet vertically. The earthquake created $92 million in damages and killed 3 people. The Big Bear Earthquake struck 3 hours following the Landers event. The earthquake caused major damage to structures, roadways, and infrastructure of the mountain community of Big Bear. 40% of the structures on the mountain were damaged and generated landslides on the three roads into the resort community isolating the area for days.

The January 9, 1994 Northridge Earthquake became the costliest seismic event in California history. The earthquake caused extensive damage to structures, the transportation infrastructure, utility systems, water storage, communications, and critical facilities. This level of damage due to the fault that ruptured was directly underneath a densely populated urban area. The Northridge Earthquake was found to raise the nearby mountains by as much as 70 centimeters. The earthquake was provided a federal disaster declaration (DR-1008).

\textsuperscript{41} City of Fullerton Local Hazard Mitigation Plan, May 21, 2020
The October 1, 1987 Whittier Narrows Earthquake shook a large part of southern California. The earthquake caused $358 million in damages, especially in the Alhambra, Pasadena, and Whittier areas. The earthquake resulted in extensive infrastructure damages, multiple injuries, and 8 fatalities. The earthquake was provided a federal disaster declaration (DR-799).

The February 9, 1971 Magnitude 6.5 San Fernando Earthquake struck the San Fernando Valley in Los Angeles just after 6am. The intense shaking caused the collapse of freeway overpasses, hospitals, and other infrastructure. It damaged thousands of homes and businesses, a reservoir, and critical infrastructure. 65 people were killed and 2,000 more were injured. The shaking was felt for 300 miles including in Las Vegas, Nevada. The earthquake was provided a federal disaster declaration (DR-299).

The March 10, 1933 Long Beach Earthquake registered at a Magnitude 6.4 occurred along the Newport-Inglewood Fault. The earthquake resulted in over $50 million in damages, 500 injuries, and 120 fatalities. Unreinforced masonry structures were the source of most of the casualties. 70 schools were destroyed and 120 were damaged. This earthquake promoted statewide standards in building design and construction for schools and other structures to better withstand seismic events.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Los Angeles area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near San Luis Obispo could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near San Luis Obispo could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Central Coast region limiting immediate assistance that the campus may normally expect.
Local impacts to the CSU San Bernardino campus caused by an earthquake could include:

- Injuries and damage related casualties
- Ground rupture
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway and roadway system
- Landslides blocking primary access routes including US 101 and CA SR 1
- Damage to rail lines transiting through San Luis Obispo
- Structural damage to bridges over waterways and flood control channels
- Damage to power grid and widespread power outages
- Disruption in water services
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to flood control facilities
- Structural damage to campus academic and support buildings
- Damage or loss of academic research, documents, electronic storage, art, and literature.
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Gaps in service delivery to vulnerable populations
- Considerable stress and fear among community
- Spontaneous creation of tent cities or outdoor camping on personal property
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the San Bernardino County fault systems surrounding CSU San Bernardino is included in the following table.

The San Bernardino County Multi-Jurisdictional Hazard Mitigation Plan identifies that the probability of an earthquake with a Magnitude 6.7 or greater occurring in Southern California in the next 30 years is estimated to be 97%.

Based on the earthquake shaking potential in the Inland Empire region, the proximity to the above listed fault systems, the probability of seismic ground shaking generating damage is considered Possible.

**Vulnerability to the Hazard**

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of CSU San Bernardino places the campus in a suburban community near residential, commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to San Bernardino generally surround the city and some cross into the city including near the CSU San Bernardino campus. The San Andreas Fault traverses the northern edge of the campus. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced

42 San Bernardino County Multi-Jurisdictional Hazard Mitigation Plan, 2017
43 Southern California Earthquake Center, Earthquake Information, [https://scedc.caltech.edu/earthquake/faults.html](https://scedc.caltech.edu/earthquake/faults.html)
individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected.

Elements of the vulnerability to a major earthquake on the CSU San Bernardino campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the area. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. As the CSU San Bernardino campus is downstream from dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.
Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $626,694,141.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater San Bernardino County, Low Desert region, and the CSU San Bernardino campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU San Bernardino campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding San Bernardino, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader San Bernardino County region creating large-scale regionwide needs for critical assistance
and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Erosion

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another”. Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable.

Location of the Hazard

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across those areas of the campus with erosion-prone characteristics.

such locations have been identified on the campus, though an effort to do so may be conducted in the future.

Extent of the Hazard

There is no published scale of severity or extent for this geologic hazard. If conditions are favorable, erosion is likely to occur. Given no history of occurrence and no known erosion prone locations on campus, the planning committee ranks the extent of the hazard as **Low**.

History of the Hazard

**There have been no recorded incidents of erosion on the CSU San Bernardino campus.**

Potential Impacts of the Hazard

Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, the probability of future occurrence for at least a limited degree of erosion occurring somewhere on the campus is **High over the long term**.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU San Bernardino infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion.

In the wider San Bernardino community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks. Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

Vulnerability Assessment Conclusions
While the ability to predict future erosion on the CSU San Bernardino campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Description of the Hazard (Extreme Heat)**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.46

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.47 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.48

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.49 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.50

**Location of the Hazard**

---

48 Ibid.

Extreme heat events are a non-spatial hazard, and may occur at the Cal State San Bernardino campus.

Extent of the Hazard

Extreme heat has a wide range of extent and severity markers and characteristics. In the City of San Bernardino, monthly average maximum temperatures in June through October range approximately from the high 80s to the high 90s. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at the San Luis Obispo Polytech Station was 113° F on September 2, 1982.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach those criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur. Given 28 excessive heat events with three events resulting in deaths and power outage emergencies, the planning committee ranks the extent of the hazard as **Moderate to High**.

Figure 19-10 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

Figure 19-10: Methodology for Determining Heat Index

---

As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been 28 excessive heat events that have affected San Bernardino County. Four deaths were attributed to a heat wave that occurred in September 2007. However, the majority of these events have not impacted the City of San Bernardino as greatly as the eastern areas of the county in terms of power outage impacts. Of the 28 excessive heat events identified for the County of San Bernardino, only two (in 2006 and 2010) have affected the city. In 2006, an excessive heat incident caused a power outage event, which then escalated to a Stage One CAISO Power Emergency and a 2010 heat wave that impacted much of the southeastern desert region.

Potential Impacts of the Hazard

During an excessive heat event, Cal State San Bernardino may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air

---

conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

**Probability of Future Occurrence of the Hazard**

The City of San Bernardino regularly experiences summertime temperatures well into the 90s. Using the scale provided, it is Possible that this hazard will occur annually.

**Vulnerability to the Hazard**

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.\(^5^4\) This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Cal State San Bernardino is aware of the potential for extreme heat events during the summertime. The county sponsors nearly 50 cooling centers that are open to the public, one located in the City of San Bernardino.

The risk of power shut-offs is of concern to the campus. While the campus has ample warning from the utility, it is a constant threat, particularly during the summertime. In 2020, the campus had its power shut off four times, with the longest outage lasting 24 hours. Several buildings and facilities were forced to run on generator power, which had a significant impact on university operations. Cal State San Bernardino has invested in sustainability measures to reduce its energy footprint and use renewable energy sources. As an example, the school adjusts cooling operations in the San Bernardino Central Plant to use less energy. The water that is used to provide conditioned air is chilled late at night to take advantage of cooler outdoor temperatures and the lower price of electricity. This water is then stored in thermal energy storage tanks which insulates the water throughout the next day.\(^5^5\)

\(^5^4\) Centers for Disease Control and Prevention. *Heat and People with Chronic Medical Conditions.* Retrieved 03.13.21 from [https://www.cdc.gov/disasters/extremeheat/medical.html](https://www.cdc.gov/disasters/extremeheat/medical.html)

\(^5^5\) CSUSB Office of Sustainability. *Energy Efficiency.* Retrieved 03.23.21 from [https://www.csusb.edu/sustainability/energy](https://www.csusb.edu/sustainability/energy)
Given the potential for hotter and more frequent heat waves due to climate change, Cal State San Bernardino may want to continue to invest in these types of strategies to handle the risks and vulnerabilities of extreme heat.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the Cal State San Bernardino campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.56

Description of the Hazard (Extreme Cold)

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.57

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.58 This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underly tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes.59 It can be permanently damaging if not treated promptly and can lead to infection, nerve

damage, or amputation in severe cases.60 The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6°F. Hypothermia occurs when your body temperature falls below 95°F.61 As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

**Location of the Hazard**

Extreme cold events are a non-spatial hazard, and may occur at the Cal State San Bernardino campus.

**Extent of the Hazard**

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in the City of San Bernardino are typically in the low 40s to mid-40s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in San Bernardino was 16°F, which was reported on two consecutive days, January 21-22, 2002. Given 8 frost/freeze events and no extreme cold events, the panning committee ranks the extent of the hazard as **Low**.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30°F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.62

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure 19-11(following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow).

---

60 Ibid.
In 2011, the National Weather Service introduced an experimental program that issued warnings for extreme cold events, independent of other severe weather warnings. The test areas included North and South Dakota and Minnesota. However, in 2012, after a single season of use, the program was abandoned, based on reports of confusion among test audiences.64

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, San Bernardino County has had eight frost/freeze events on record dating back to 1998, but no extreme cold hazards. [Records for this hazard were first recorded in 1996].

Potential Impacts of the Hazard

Should an extreme cold event occur, Cal State San Bernardino might experience impacts due to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

Probability of Future Occurrence of the Hazard

The City of San Bernardino has experienced frost/freeze events, but has never experienced an extreme cold event. Due to the campus’s location in a temperate climate, it is Unlikely that this hazard will occur annually.

Vulnerability to the Hazard

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more likely to suffer illness or death as a result.65 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Cal State San Bernardino is one of the CSU campuses facing the greatest variance in temperatures. Wintertime low temperatures average out in the 40s, while summertime highs are typically in the 90s. The campus has faced several freeze/frost events, but cold nighttime temperatures in the fall and winter are not unusual due to the Santa Ana winds.

Estimate of Potential Losses

Based on the previous historical occurrences of extreme cold events, annualized losses are considered to be negligible. In an extreme cold event, loss of human life or health impacts are a greater concern than is property damage.66

Vulnerability Assessment Conclusions

While the ability to predict future extreme cold events at the Cal State San Bernardino campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), areas of Southern California have warmed approximately three degrees on average over the last century, with less rainfall. This may lead to fewer frost/freeze events in the future.67

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

Flood

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that

are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.
may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric Rivers**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California, they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Location of the Hazard

San Bernardino is located in the eastern end of the Inland Empire region of Southern California. San Bernardino is comprised of a diverse geography including dense urban areas, suburban neighborhoods, heavy industry, open fields, vegetation filled valleys, and the elevation rise into the San Bernardino Mountains. The City of San Bernardino sits at the base of the San Bernardino National Forest and steep mountain slopes. Along the northern edges of the CSU San Bernardino campus is the boundary to hillsides and drainages from higher elevations. These ravines drain the mountains that the campus sits below into the Devils Canyon and surrounding drainages. The Devils Canyon Reservoir facilities provide water distribution control for the State Water Project and local flood control that contribute to the potential for flooding on campus. The area surrounding the campus is a combination of developed suburban environments predominately consisting of residential and commercial land uses and open hillsides.

The CSU San Bernardino campus is entirely located in a designated Zone X: Area with Reduced Flood Risk Due to Levee. The access routes into and out of the campus servicing locations to the west and south are found in areas primarily designated as Zone X. The CSU San Bernardino campus is located adjacent to the Devils Canyon reservoir. The campus is situated in a valley between the San Bernardino Mountains and the Shandin Hills. The mountains to the north of the campus rise to over 5,000 feet in elevation and provide a collection source for the orographic effect of Pacific storms. The campus and the surrounding neighborhoods sit on a gentle slope allowing for most localized precipitation to drain south and away from the campus. The northern San Bernardino neighborhoods are served by a series of catchment basins and flood control channels to further distribute water.
Extent of the Hazard

The CSU San Bernardino campus is entirely located in a designated Zone X: Area with Reduced Flood Risk Due to Levee. The access routes into and out of the campus servicing locations to the west and south are found in areas primarily designated as Zone X: Area of Minimal Flood Hazard, access routes to and from the east are primarily located in Zone X: Area with Reduced Flood Risk Due to Levee or Zone X: 0.2% Annual Chance Flood Hazard. The CSU San Bernardino, Palm Desert Campus is entirely located in a designated Zone X: Area of Minimal Flood Hazard. The access routes into and out of the Palm Desert Campus are found in areas primarily designated as Zone X: Area of Minimal Flood Hazard. Based on the campus’ location in a minimal flood risk zone, and a history of limited and localized flooding, the planning committee ranks the extent of the hazard as Low.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

---

Table 19-21: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised map in place of Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, BFEs derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
<tr>
<td>Zone AH</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.</td>
</tr>
<tr>

</tbody>
</table>
Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.

History of the Hazard

Flooding in San Bernardino and the broader Inland Empire region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the CSU San Bernardino campus. No record of flood events are reported for the campus, but in general, occasional heavy rainfall events will produce limited and localized ponding in low lying areas.

70 San Bernardino County Multi-Jurisdictional Hazard Mitigation Plan, 2017
Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Inability for campus operations to resume
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard
San Bernardino County is determined have considerable portions of the county to be at high risk from flooding. Flooding is the second most common and widespread hazard identified by the County. San Bernardino County has experienced 10 flooding events since January of 2010. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common in the San Bernardino area with winter storms saturated with subtropical moisture. The CSU San Bernardino campus is located within a Zone X Special Flood Hazard Area (Area with Reduced Flood Risk Due to Levee) and borders a Zone A (Area Inundated by 1% Annual Chance for Flooding). There are specific buildings and areas of the campus that have a greater risk for isolated flooding.

The probability of future occurrence for flooding is **Unlikely**.

**Vulnerability to the Hazard**

The CSU San Bernardino campus is subject to the effects of limited and localized flooding resulting primarily from excessive precipitation and isolated strong storms. There is a remote potential for flooding and damage on campus and surrounding residential and commercial areas of northern San Bernardino due to overflow or damage to flood control systems at Devils Canyon. The channels and extending irrigation channels that surround the campus have limited storage or volume capacities. However, the campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the CSU San Bernardino campus will vary depending on when the flood were to occur and depending on whether any people and assets are located near low lying flood prone areas where localized flooding or ponding occurs. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community may become trapped on campus depending on the level of flooding occurring on surface streets. However, during low probability, severe region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

CSU San Bernardino is in proximity to a variety of industrial and commercial facilities in the areas east of the campus. When these facilities are inundated with flood water, the potential for chemical release exists presenting possible exposures to individuals from the campus community. These facilities additionally line many of the primary access routes in and out of the campus. The areas that these facilities reside are lower in elevation than the campus.

The campus sits on land that slowly elevates towards the San Bernardino Mountains that are situated behind the university limiting the effects of widespread flooding. Some campus buildings and infrastructure might be vulnerable to localized flooding if it reaches the university. Campus utilities and communication capabilities might be impacted by flood waters rendering them disabled. A low probability flood covering a large portion of
the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. Flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings in any areas of the campus prone to localized flooding.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $626,694,141. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets exposed to mostly localized flooding and ponding from overflow of campus creeks or isolated or large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. In addition to localized flood vulnerabilities, the proximity to the Devils Canyon system presents an additional hazard for the campus.

The potential for flooding generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Hazardous Materials

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or
significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards:** fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards:** carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a

---

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. The planning committee indicates that chemicals are located in science labs on campus, and mapping indicates that hazardous waste sites, gas pipeline and a rail line are located near campus. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city and county of San Bernardino, and reflect different types, configurations and scales dispersed across these geographic areas.

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

For the CSU – San Bernardino planning committee, chemicals are managed in campus science labs, and no events have taken place on campus. The rail line, gas pipeline and waste sites are approximately ½ mile from the campus. Based on these factors, the extent of the hazard for the CSU – San Bernardino campus is Low, but to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and

recover from immediate disaster threats, and that responsible parties may have an
incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill
Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already
2096 spill events had occurred. Such events have occurred in all the cities and/or counties
where CSU campuses are located. 76

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-
technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past
earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

According to the campus planning committee, no events have taken place on campus.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under
certain conditions related to direction of air flow (air-based chemical release) and
population density or the contamination of a community’s main water supply. Either type
of release could necessitate large scale evacuation. By contrast, in the rural
unincorporated areas where population densities are low, even in the event of a large
release, the number of homes that may need to be evacuated would be significantly
lower than in an urban environment. The occurrence of a hazmat incident can also result
in the shut-down of transportation corridors which can last for hours at a time while the
impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if
absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources
become unsafe and unusable, depending on the amount of contaminant. Some
chemicals cause painful and damaging burns if they come in direct contact with skin.
Prolonged and concentrated exposure to such chemicals can produce severe long-term
impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the
students, staff and environment on the CSU – San Bernardino campus.

With regard to the natural environment overall, contamination of air, ground, or water
may result in harm to fish, wildlife, livestock, and crops. The release of hazardous
materials into the environment may cause debilitation, disease, or birth defects over a
long period of time. Loss of livestock and crops may lead to economic hardships within
the community.

76 Cal OES. Spill Report View. Retrieved 04.21.2021 from:
https://w3.calema.ca.gov/operational/malhaz.nsf/$defaultView?OpenView&Start=121&ExpandView
Recent California examples include the 2016 Aliso Canyon methane gas leak\(^77\), which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. \(^78\) Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impacts of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – San Bernardino) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

**Probability of Future Occurrence of the Hazard**

The probability of occurrence for a hazmat event on the CSU – San Bernardino campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low - the campus has not experienced a hazmat event on campus. In addition, hazardous materials and

infrastructure ½ mile away may increase vulnerability and the probability of a campus-
related event. Moreover, hazmat occurrences are largely based on human error, and any
changes in risk and vulnerability factors such as a decreased vigilance in materials
oversight and handling practices or changes in the amount of chemicals or exposure will
likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the CSU – San Bernardino campus. As identified by
the campus planning committee and on the hazmat map, the following vulnerabilities are
present on campus: chemicals are present in science and research labs. In addition, a rail
line, gas pipeline and several hazardous waste sites are about ½ mile to the campus
footprint. Gases and chemicals or hazardous waste, if spilled or released, could impact
human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because
(unlike natural hazards) the probability of occurrence is dependent on human error, which
itself is variable based upon a fluctuating set of interrelated factors, some of which lack
prediction or control, given the complexity of how all natural and built environments and
hazmat risks factors interrelate at the local or campus level, it is prudent to assume for
planning purposes that the campus’ vulnerability is a sub-set of the larger community’s
vulnerability. As such, the CSU – San Bernardino leadership maintains vigilance to
mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate
quantitative measure of vulnerability because of the variable nature of a hazardous
materials spill. For example, the release of a toxic airborne chemical in a populated area
has severe impact potential, whereas the impact potential of a small chemical spill in a
remote or rural area is most likely limited to remediation of soil. And, in both cases, the
probability of occurrence is dependent on human error, which itself is variable based
upon a fluctuating set of interrelated factors, some of which lack prediction or control. In
all cases, different types and amounts of hazardous materials interact with fluctuating
combinations of human error to produce different event outcomes with variable impact
costs.
Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – San Bernardino) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the San Bernardino County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – San Bernardino campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – San Bernardino planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high

---

earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 19-15. Based on the Figure below, the campus is adjacent to landslide susceptibility zones and sits between two small areas of high susceptibility.

Figure 19-15: Deep-seated Landslide Susceptibility Surrounding CSU San Bernardino

Extant of the Hazard

In San Bernardino, landslides are more likely to occur in the steep slopes to the north and south of the city. The San Gabriel mountains, both steep and erosive, contain steeply walled canyons above areas with high population density. When heavy rain occurs, there is significant potential for floods and landslides throughout the County, and indirect impacts may cover a larger geographical extent. Based on the campus’ close proximity to

---

the landslide hazard zone, and the history of significant impacts in the county, the planning committee ranks the extent of the landslide hazard for the campus as **Moderate**.

**History of the Hazard**

FEMA has declared twelve major disasters involving landslides, mudslides, mud flows, and debris flows since 1978 in San Bernardino County. NOAA recorded thirty debris flow events from 2003 to 2019. On December 25, 2003, a landslide formed in the San Bernardino Mountains and filled the percolation basins located 3.5 miles north of San Bernardino City center, resulting in 14 casualties and $5 million in damage. The landslide was induced by rainfall. No landslides have been reported on or immediately adjacent to the campus.

**Potential Impacts of the Hazard**

CSU San Bernardino may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly affect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

**Probability of Future Occurrence of the Hazard**

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in the San Gabriel Mountains and therefore are highly likely to occur in the future. Given the location of the campus adjacent to the landslide zone, and the occasional occurrence of severe landslides in the county, the planning committee ranks the probability of the landslide hazard in some way affecting the campus as **Possible**.

**Vulnerability to the Hazard**

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The
structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress.

Any population proximal to a landslide when it occurs is vulnerable to its impacts.

Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU San Bernardino.

Vulnerability Assessment Conclusions

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the CSU San Bernardino campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.
**Power Outage**

**Description of the Hazard**

San Bernardino is a city situated in an area of Southern California known as the Inland Empire. Located in San Bernardino County, the City of San Bernardino has a span of nearly 60 square miles and is the home of CSU San Bernardino. The city and county are situated within a valley topography. San Bernardino is unique among Southern Californian cities because of its wealth of water, which is mostly contained in underground aquifers; a large part of the city is over the Bunker Hill Groundwater Basin, including Downtown.

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly populated areas like San Bernardino without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the CSU San Bernardino campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of SJSU student residents in on-campus housing would also be affected by a power outage on campus and in the area.

Additionally, a severe outage to San Bernardino would also directly affect the campus and the community.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions are:

- **Planned:** Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- **Unscheduled:** Some intentional disruptions must be done "on the spot" in response to an emergency.
- **Demand-Side Management:** Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- **Load Shedding:** When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.
Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, as a hazard, it has the potential to occur and affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached.

A power outage could affect the entire area of the campus, including the CSU San Bernardino athletic fields, classrooms resident halls, administrative offices, virtual, telephonic and radio communications, leading to loss of lighting in campus parking structures, and creating a cascading hazard for commuters as they depart from or arrive to campus in the evening. Additionally, the university is located within proximity of highly utilized thoroughfares for the transportation of goods to throughout California, within one of the busiest areas of the Inland Empire.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. However, given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.
History of the Hazard

The City of San Bernardino has experienced major power outages in the past, affecting a large number of residents. Some of the most recent power outage events include the following:

- September 5, 2020: Rolling power outages occurred in an effort to conserve energy due to an overwhelmed grid and Public Safety Power Shut-offs due to extreme heat and wind events occurring in San Bernardino County.
- December 7, 2020: Southern California Edison cut electricity to more than 43,000 of its customers in public safety power shutoffs as Santa Ana winds battered much of the region.
- January 19, 2021: High wind events prompted SCE to create outages through Public Safety Power Shut offs.

The CSU San Bernardino campus has also experienced power outages in recent years:

- October 10, 2019: Cal State San Bernardino closed because of an electricity outage aimed at mitigating the threat of wildfires amid dry, windy conditions in Southern California.

Potential Impacts of the Hazard

Instructors, campus residents, staff, and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter
temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City of San Bernardino experiences such outages. As such, the probability ranking for the San Bernardino area is **Likely**. Since the CSU San Bernardino campus has also recorded power outage events, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

**Estimate of Potential Losses**

The data provided by Cal State San Bernardino State does not report any value for potential losses due to power outage.

**Vulnerability Assessment Conclusions**

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at SJSU. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a
power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, classrooms may not be usable if lighting equipment is not functioning, impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

Cal State San Bernardino did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU San Bernardino or San Bernardino County is within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While CSU San Bernardino does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.
Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU East Bay is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU San Bernardino.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU San Bernardino, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses
Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

**Vulnerability Assessment Conclusions**

CSU San Bernardino is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

**Identified Data Limitations**

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

**Wildfire**

**Description of the Hazard**

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire

84 **State of California Hazard Mitigation Plan**, September 2018
growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially influence the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests, and other lands with high susceptibility to fire occurring throughout the state. CSU San Bernardino is located along the base of the San Bernardino Mountains and at the opening of the Cajon Pass. Areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur to the east, west, north, and south of the campus. Additionally, these fire hazard zones exist in other areas throughout San Bernardino County. These areas surrounding the valley are topographically diverse,
contain heavier vegetative fuels, and often have residential development interspersed. The land in the San Bernardino Valley where the CSU San Bernardino campus is located, is largely developed with a variety of mixed land uses. The North San Bernardino neighborhoods surrounding the campus exist within wildland-urban interface area with a history of destructive fires.

The CSU San Bernardinno campus is located in the northern portion of the City of San Bernardino and bordering open lands that are within the San Bernardino National Forest. The areas immediately to the south and east of the campus are predominately residential neighborhoods. The areas to the west and north include open hillsides with dense vegetation. Fire Hazard Severity Zones are found throughout the campus and throughout the hillsides surrounding the campus to include Very High Fire Hazard Severity Zones (VHFHSZ).

CSU San Bernardino further is located at the opening of the Cajon Pass providing over mountain access from the San Bernardino Valley to the California High Desert. This pass is also the sight of a funneling of winds in “Santa Ana” wind conditions. These offshore winds result when high pressure builds over the Great Basin or Upper Mojave Desert. The high-pressure systems push air into the mountain passes of the Transverse Ranges and through the few passes through the mountains. As the air is funneled through these passes, the wind narrows and is compressed causing the velocity to increase significantly. The relative humidity during these events is often critically low. These downslope winds are extremely dry and strong adding to enhanced fire threat or increases the intensity of existing fires. The CSU San Bernardino campus is just 5 miles from the opening of the Cajon Pass at Devore, CA.
Figure 19-16: Fire Hazard Severity Zones, CSU San Bernardino

Figure 19-17: Fire Hazard Severity Zones, San Bernardino, CA

Extent of the Hazard

While the threat to fire directly affecting the campus is considerable, the direct effect of fire generated smoke is also likely to occur. Fires are likely to occur in close proximity to the campus generating smoke that could envelop the campus in the right atmospheric conditions. Fires that are large enough to generate volumes of smoke to cover great distances have the potential to affect the air quality of the San Bernardino County and Inland Empire area including the campus. This will especially be the case in weather conditions creating strong offshore Santa Ana Winds. The potential for this impact has been demonstrated during the summers of 2018, 2019, and 2020 as fires burned across the state and spread smoke over vast distances. Fires burning well outside of the San Bernardino County region have the potential to distribute smoke onto the CSU San Bernardino campus.

The area immediately surrounding the CSU San Bernardino campus is in direct proximity to fire hazard zones designated as High or Very High Fire Hazard Severity Zones. The County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. Based on the above factors, the planning committee ranks the extent of the hazard for the campus as **High**.
The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 19-24: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel -- especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>

</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Color Code</th>
<th>Class Description</th>
<th>Fire Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Orange</td>
<td>Class 4: Very High Danger (VH)</td>
<td>Fires start very easily and spread at a very fast rate. Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</td>
</tr>
<tr>
<td>Red</td>
<td>Class 5: Extreme (E)</td>
<td>Fire situation is explosive and can result in extensive property damage. Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</td>
</tr>
</tbody>
</table>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. San Bernardino County also has a long history of wildfire activity primarily along the foothills and in the mountains. Wildfires occurring in the San Bernardino County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damages.

The campus does have a history of wildfire activity occurring within direct proximity to the campus. Additionally, the campus has experienced the effects of large wildfires occurring elsewhere in San Bernardino County. The campus closed due to fires in 1980 and 2003. The San Bernardino campus has experienced days of poor air quality due to fires burning in parts of the county, although infrequent.

89 California Department of Forestry and Fire Protection, Stats and Events, [https://www.fire.ca.gov/stats-events/](https://www.fire.ca.gov/stats-events/)
90 San Bernardino County Multi-Jurisdictional Hazard Mitigation Plan, 2017
The Panorama Fire ignited on November 24, 1980, because of an arsonist. Strong Santa Ana winds gusting up to 90 miles per hour quickly pushed the fire from the San Bernardino Mountains downhill into the neighborhoods of northern San Bernardino. The fire would destroy 425 structures, burn 28,800 acres, and kill 5 people. The fire would also burn onto the CSU San Bernardino campus and destroy the Shipping and receiving Warehouse and severely damage the campus’ cooling towers.

The Old Fire started on October 21, 2003 in Waterman Canyon near the point of ignition for the Panorama Fire. This Arson caused fire would end up consuming much of the southern facing slopes of the San Bernardino Mountains pushed by strong Santa Ana Winds. This fire would ultimately merge with the Grand Prix Fire. The Old Fire burned 91,281 acres, destroyed 1,003 structures including over 900 homes, forced over 80,000 people to evacuate, and killed 6 people. The fire burned onto the CSU San Bernardino campus destroying modular classrooms, damaged others, and burned landscaping.

Potential Impacts of the Hazard

The location of the CSU San Bernardino campus surrounded by areas designated as High or Very High Fire Hazard Severity Zones places a threat of flame, ember, and smoke exposure from wildfire to the campus. There is potential for fire to occur on three sides of the campus and in the surrounding hillsides composed of light to moderate fuels. The threat of these neighboring hillsides to campus structures is substantial.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction of damage
- Residential property destruction or damage
- Damage to residence halls located along borders of campus
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or disrupted transportation, lifelines, and supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Potential for community wide evacuation
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Threat to Murillo Family Observatory
- Threat to Animal House
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Inland Empire including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

**Probability of Future Occurrence of the Hazard**

Based on the wildfire threat potential in the area surrounding the CSU San Bernardino campus and hillsides along the north and east side of the campus, including the immediate proximity to Local Fire Hazard Severity Zones listed as “Very High”, the density of residential and commercial development, and the historic occurrences of fires, the annual probability of wildfire related damage on the campus is considered Possible.

Based on the wildfire threat potential in the area surrounding Southern California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality on campus is considered Possible.

**Vulnerability to the Hazard**
The CSU San Bernardino campus is subject to direct impact from wildfire due to the campus location within a wildland-urban interface zone. The campus is identified to reside within designated local Very High Fire Hazard Severity Zones. The campus is surrounded by hillsides and open lands containing combustible vegetation combined with residential development. Additionally, vulnerabilities to the effects of wildfire would lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillsides adjacent to the campus and extending onto the campus or localized fires involving single structures or small areas in the surrounding neighborhoods. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These localized incidents occur periodically throughout the year in this area around CSU San Bernardino. Incidents of this nature could likely have significant impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures. Structures with vegetation and other combustibles near the structure increases the ability of fire to spread to buildings.

Depending on the extent of a wildfire affecting the campus, access could become cutoff during fire incidents. The campus is served by three roadways providing access on and off of university grounds. University Parkway is the primary route providing access to Interstate 215, Campus Parkway provides the western side of the campus access to Kendall Drive, and NorthPark Blvd allows access to into the neighborhoods east and south of the campus. The availability of these access routes will be dependent upon the conditions at the time of the event. The primary routes including Kendall Drive and Interstate 215 could also be impacted by larger fires extending beyond the area of the campus restricting access and generating congestion closer to the campus. The university is limited by these routes for access to and from the campus. Access for supplies, equipment, and emergency services in addition to evacuation away from the campus would likely be forced to use alternative routes through the northern San Bernardino area.

The greater concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Inland Empire even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU San
Bernardino students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU San Bernardino campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-fire environment. Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $626,694,141. However due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been frequent in San Bernardino County, including wildfire incidents that have threatened or caused damages near the CSU San Bernardino campus. The location of the CSU San Bernardino campus surrounded by open hillsides with light to moderate vegetative fuels along the entire northern edges presents a threat of fire to the campus community and campus assets. The placement at the opening of the Cajon Pass and the Santa Ana Winds coming down the pass exacerbate the threat provide greater emphasis on campus vulnerabilities to fire. The foothills and mountains surrounding San Bernardino County host environments that are ideal for the development of wildfire activity. The consequences of fires in these areas would present primary and secondary consequences to the CSU San Bernardino campus and expose vulnerabilities on the campus and to the campus community.

The topography of the valley surrounded by mountains allows for smoke filled air to linger in the valleys of the Inland Empire with the potential for unhealthy air quality depending on wind conditions. Fires in the watersheds of the San Bernardino and San Gabriel Mountains and tributaries may damage vegetation stabilizing hillsides and result in increased sediments to be discharged into the river system and reservoirs reducing their capacity and effectiveness.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.
Severe Weather (Wind, Tornado, Hail, Lightning)

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases are associated with significant changes in weather patterns around the world.
lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.\(^{95}\)

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California.\(^{96}\) On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions.\(^{97}\) This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU San Bernardino.

**Regional Climate Influences on Severe Weather across California**

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.\(^{98}\)

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU San Bernardino), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.\(^{99}\)

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage. The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California. These storms affect (in varying degrees) all CSU campuses, including CSU San Bernardino.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. Severe thunderstorms are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.

- **Wind storm**: marked by high wind with little or no precipitation.

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.

---

105 Retrieved on 07.15.2021 from [https://www.noaa.gov/explainers/severe-storms](https://www.noaa.gov/explainers/severe-storms)

106 Retrieved on 07.15.2021 from [https://www.weather.gov/safety/thunderstorm](https://www.weather.gov/safety/thunderstorm)

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.\(^{110}\)

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\(^{111}\)

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\(^{112}\)

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\(^{113}\) Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” \(^{114}\)

---

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Donslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU San Bernardino).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\(^\text{115}\)

**Strong Winds**

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\(^\text{116}\)

**Thunderstorm Winds**

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\(^\text{117}\)

Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\(^\text{118}\) However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

**Tornadoes**

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\(^\text{119}\) This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from

\(^\text{118}\) Retrieved on 07.15.2021 from [https://www.nssl.noaa.gov/education/svrwx101/wind/types/](https://www.nssl.noaa.gov/education/svrwx101/wind/types/)

\(^\text{119}\) Retrieved on 07.15.2021 from [https://www.earthnetworks.com/tornado/](https://www.earthnetworks.com/tornado/)
the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\textsuperscript{120} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{121}

**Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.**

*Santa Ana Winds.* A type of wind hazard that is peculiar to Southern California is called a *Santa Ana Wind.* Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{122} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{123} (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

---

\textsuperscript{120} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/
\textsuperscript{121} Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions
\textsuperscript{123} Retrieved on 07.13.2021 from https://www.weather.gov/safety/wind-mountain-valley
What Drives a Santa Ana Wind?

1. High surface pressure builds over the Great Basin region with lower pressure off Southern Cal Coast. (Fall-mid Spring)

2. Air remains relatively cold across the deserts. As the air extends through the mountain passes...it become compressed and warms. (See lower right map) Lower relative humidity also occurs helping to dry out vegetation and can fan any existing fires.

3. Wind speed increases as it squeezes through the mountain and valley canyons. Wind gusts can vary from 45 to 100 mph depending on the strength of the Santa Ana event.

4. Strong winds create turbulence for area flights and can make interstate travel difficult as well as choppy seas for mariners.

Diablo Winds. The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.\(^\text{125}\)

Sundowner Winds. Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and

\(^{125}\) Retrieved on 07.13.2021 from https://www.fireweather.org/diablo-winds
coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.\footnote{126} \footnote{127} \footnote{128}

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.\footnote{129} It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.\footnote{130}

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\footnote{131}

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{132} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including either at the CSU San Bernardino main campus or at satellite campus facilities owned by the school. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all CSU San Bernardino campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU San Bernardino campuses reflect those of the surrounding community and County. As a result, all assets and people at CSU San Bernardino campuses are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the San Bernardino (San Bernardino County) and Palm Desert (Riverside County) areas, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.\textsuperscript{133} First developed in 1805, it is still used today to estimate wind strengths.\textsuperscript{134}

---

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.
**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.136

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 19-28: Fujita Tornado Scale (Pre-February 2007) 137

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as LOW.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms.\textsuperscript{141} \textsuperscript{142} That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light*, *medium*, or *heavy* according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\textsuperscript{143}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{144}
- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{145} or
- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\textsuperscript{146} \textsuperscript{147}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

\textsuperscript{141} Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
\textsuperscript{142} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
History of the Hazard

Severe weather hazards have been an annual occurrence in San Bernardino and on the CSU San Bernardino campus. Historical data for these hazards are presented below.

Historical Storm Data Collection: NCEI Storm Events Database

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\textsuperscript{148} For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\textsuperscript{149} To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

San Bernardino County

Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in San Bernardino County since 1996.\textsuperscript{150} Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\textsuperscript{151}

- **High Wind**: at least 493 events, or approximately 19.46 events per year\textsuperscript{152}

\textsuperscript{150} National Climatic Data Center. Storm Events Database. Retrieved 07.19.2021 from https://www.ncdc.noaa.gov/stormevents/
\textsuperscript{151} National Climatic Data Center. Storm Events Database. Retrieved 07.19.2021 from https://www.ncdc.noaa.gov/stormevents/
\textsuperscript{152} National Climatic Data Center. Storm Events Database. Retrieved 07.30.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SAN%2BBERNARDINO%3A71&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitButton=Search&statefips=6%2CCALIFORNIA
- **Strong Wind**: at least 70 events, or 2.76 events per year\(^\text{153}\)
- **Thunderstorm Wind**: at least 116 events, or approximately 4.58 events per year\(^\text{154}\)
- **All Wind Hazard events** (excluding Tornadoes): at least 673 events, or approximately 26.57 events per year.\(^\text{155, 156}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in San Bernardino County, there have been at least 673 wind hazard events since 1996, excluding tornadoes.\(^\text{157, 158}\) That translates to an approximate average historical frequency of occurrence of **26.57** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 679 events) and simultaneous Database searches of all severe weather hazard events (i.e., 673 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;“ and/or (2) severe weather hazard events such as “Thunderstorm Wind”

or “Hail” that are reported for San Bernardino County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{159} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 673 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

### Historical Wind Hazard Losses for San Bernardino County since 1996

According to the NCEI Storm Events Database, the wind hazard events that San Bernardino County has experienced since 1996 have been costly. There have been 4 deaths and 42 injuries, and property and crop damage estimates have totaled approximately $52,873,000 and $2,000,000, respectively.\textsuperscript{160} 161

#### Tornado Wind Hazards

Information from the NCEI Storm Events Database indicates that since 1996, there have been 16 reported events of tornadoes in San Bernardino County, which translates to approximately 0.63 tornado events per year.\textsuperscript{162}

The 11 out of the 16 the tornadoes reported in San Bernardino County since 1996 have been of tornadoes with a severity rating of F0/EF0. Each of the remaining five (5) tornadoes have had a severity rating of F1/EF1; that translates to approximately 0.20 events of F1/EF1 tornadoes that have occurred per year in San Bernardino County.\textsuperscript{163}

Historical Tornado Hazard Losses for San Bernardino County since 1996

According to the NCEI Storm Events Database, the tornado hazard events that San Bernardino County has experienced since 1996 have been moderate. There have been no deaths, injuries, or crop damages reported, but property damage estimates have totaled approximately $41,000.164

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 52 reported events of hail in San Bernardino County, which translates to approximately 2.05 hail events per year.165 (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 53 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from San Bernardino County. The origin of this error is unknown at this time.)

Historical Hail Hazard Losses for San Bernardino County since 1996

According to the NCEI Storm Events Database, the hail hazard events that San Bernardino County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damages reported, property damage estimates have totaled approximately $358,100.166 (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in San Bernardino County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 55 reported events of lightning in San Bernardino County, which translates to approximately 2.17 lightning events per year.167

Historical Lightning Hazard Losses for San Bernardino County since 1996

According to the NCEI Storm Events Database, the lightning hazard events that San Bernardino County has experienced since 1996 have been costly. There have been 3 deaths and 9 injuries, and property damage estimates have totaled approximately $1,343,000; reported crop damage estimates have been negligible (i.e., $100).168

All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database

Information obtained from the NCEI Storm Events Database indicates that there have been 796 occurrences of the severe weather hazard in San Bernardino County. This translates to 31.42 severe weather hazard occurrences per year.169 170

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 803 events) and simultaneous Database searches of all severe weather hazard events (i.e., 796 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for San Bernardino County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.171 When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 796 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

171 Dos Santos, Renato. (2016). Some Comments on the Reliability of NOAA’s Storm Events Database. SSRN
According to the NCEI Storm Events Database, the severe weather events that San Bernardino County has experienced since 1996 have been costly. There have been 7 deaths and 51 injuries, and property and crop damage estimates have totaled approximately $54,615,000 and $2,000,000, respectively.\(^{172}\) It is important to note that for all San Bernardino County severe weather hazard events recorded on the Storm Events Database, more than half of all deaths, the vast majority of injuries, all estimated crop damage, and approximately 96.8% of all estimated property damage have been caused by wind hazard events alone.

**Riverside County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Riverside County since 1996.\(^{174}\) Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\(^{175}\)

- **High Wind**: at least 486 events, or approximately 19.18 events per year\(^{176}\)
- **Strong Wind**: at least 44 events, or 1.74 events per year\(^{177}\)

Historical Wind Hazard Losses for Riverside County since 1996

According to the NCEI Storm Events Database, the wind hazard events that Riverside County has experienced since 1996 have been costly. There have been three (3) deaths and 40 injuries, and property and crop damage estimates have totaled approximately $62,933,000 and $65,000, respectively.  

Tornado Wind Hazards

Information from the NCEI Storm Events Database indicates that since 1996, there have been 18 reported events of tornadoes in Riverside County, which translates to approximately 0.71 tornado events per year. While the vast majority of tornado reports in Riverside County since 1996 have been of tornadoes with a severity rating of F0/EF0, there have been (3) F1/EF1 tornadoes and one (1) EF2 tornado also reported.

Historical Tornado Hazard Losses for Riverside County since 1996

According to the NCEI Storm Events Database, the tornado hazard events that Riverside County has experienced since 1996 have been costly. While there have been no deaths or crop damages reported, there have been three (3) injuries, and property damage estimates have totaled approximately $21,486,000.

All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database (Riverside County)

Information obtained from the NCEI Storm Events Database indicates that there have been 704 occurrences of the severe weather hazard in Riverside County. This translates to **27.79** severe weather hazard occurrences per year.\(^{193}\) \(^{194}\)

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 710 events) and simultaneous Database searches of all severe weather hazard events (i.e., 704 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado;” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Riverside County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{195}\)

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 704 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical, Aggregated Severe Hazard Losses for Riverside County since 1996

According to the NCEI Storm Events Database, the severe weather events that Riverside County has experienced since 1996 have been costly. There have been four (4) deaths and 51 injuries, and property and crop damage estimates have totaled approximately **$84,685,000** and **$75,100**, respectively.\(^{196}\) \(^{197}\) **It is important to note that for all Riverside**
County severe weather hazard events recorded on the Storm Events Database, 75% of all deaths, 78.4% of all injuries, 74.9% of all estimated property damages, and 86.6% of all estimated crop damages have been caused by wind hazard events alone.

Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April. From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Diablo Winds

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.²⁰³
Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{204}

Figure 19-21: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\textsuperscript{205}

\textbf{Sundowner Winds}

Strong sundowner wind events occur approximately \textit{2-3 times per year}. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\textsuperscript{206}

\textbf{Historical Frequency of All Severe Weather Hazards}

Table below shows the average historical frequency of severe weather hazard events for San Bernardino County since 1996.)

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within CSU San Bernardino campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU San Bernardino campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

**CSU San Bernardino Main Campus, San Bernardino (San Bernardino County)**

According to the 2016 City of San Bernardino Hazard Mitigation Plan Update, High Winds/Straight Line Winds and Tornado hazards are each considered to have a “Low” or minimal potential impact on the city and (by extension) on the CSU San Bernardino main campus.\(^\text{207}\)

**CSU San Bernardino – Palm Desert Campus, Palm Desert (Riverside County)**

According to the 2018 County of Riverside Multi-Jurisdictional Local Hazard Mitigation Plan, wind hazards (excluding tornadoes) are considered to have a moderate to high potential impact, and tornadoes are considered to have a moderate potential impact on Riverside County and (by extension) on the CSU San Bernardino – Palm Desert Campus.208

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

**CSU San Bernardino Main Campus, San Bernardino (San Bernardino County)**

According to the 2016 City of San Bernardino Hazard Mitigation Plan Update, hail is considered to have a “Low” or minimal potential impact on the city of San Bernardino and (by extension) on the CSU San Bernardino main campus.209

**CSU San Bernardino – Palm Desert Campus, Palm Desert (Riverside County)**

The 2018 County of Riverside Multi-Jurisdictional Local Hazard Mitigation Plan does not include the hail hazard as significant enough to profile; as a result, the hail hazard is considered to have a minimal potential impact on Riverside County and (by extension) on the CSU San Bernardino – Palm Desert Campus.210

**Lightning**

Lightning strikes the United States about 20-25 million times a year.211 Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.212 Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.213 (Commercial claim payouts for lightning losses for the U.S. were not available.)

---

**CSU San Bernardino Main Campus, San Bernardino (San Bernardino County)**

According to the 2016 City of San Bernardino Hazard Mitigation Plan Update, lightning is considered to have a “Medium/Limited” or moderate potential impact on the city and (by extension) on the CSU San Bernardino main campus.  

**CSU San Bernardino – Palm Desert Campus, Palm Desert (Riverside County)**

The 2018 County of Riverside Multi-Jurisdictional Local Hazard Mitigation Plan does not include the lightning hazard as significant enough to profile; as a result, the lightning hazard is considered to have a minimal potential impact on Riverside County and (by extension) on the CSU San Bernardino – Palm Desert Campus.

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year. Future occurrences of such events are projected to increase in both their frequency and intensity.

**CSU San Bernardino Main Campus, San Bernardino (San Bernardino County)**

The 2016 City of San Bernardino Hazard Mitigation Plan Update states that wind and lightning severe weather hazards each have a “High” (i.e., “Highly Likely/Likely”) probability of future occurrence in the County, while tornadoes and hail each have a “Low” (i.e., “Unlikely”) probability of future occurrence in the County. Also, according to the NCEI Storm Events Database, some of these same severe weather hazards (i.e., wind and lightning) have occurred in San Bernardino County more than once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of both CSU San Bernardino main campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU San Bernardino main campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2016 City of San Bernardino Hazard Mitigation Plan Update and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU San Bernardino campus at least once on an

---

annual basis. Therefore, the probability of future occurrence of the severe weather hazard for the CSU San Bernardino main campus is **HIGHLY LIKELY**.

**CSU San Bernardino – Palm Desert Campus, Palm Desert (Riverside County)**

The 2018 County of Riverside Multi-Jurisdictional Local Hazard Mitigation Plan states that there is a moderate possibility that high wind hazard events will occur in the County occasionally (i.e., once every 5 years) in the future.\(^{217}\) However, according to the NCEI Storm Events Database, severe weather wind hazards have occurred in Riverside County far more than once annually – at an average of 25.18 events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU San Bernardino – Palm Desert campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for CSU San Bernardino – Palm Desert reflect those of the surrounding community and County identified in the Table below.

Taking into account the data available from both 2018 County of Riverside Multi-Jurisdictional Local Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the for CSU San Bernardino – Palm Desert campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU San Bernardino – Palm Desert is **HIGHLY LIKELY**.

**CSU San Bernardino – All Campus Areas**

The probability of future occurrence of the severe weather hazard for all CSU San Bernardino campus areas is **HIGHLY LIKELY**.

The following tables show the probabilities of future occurrence for component severe weather hazards for CSU San Bernardino campuses in San Bernardino County and Riverside County.

Vulnerability to the Hazard

People, structures, and assets on both CSU San Bernardino campuses are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The CSU San Bernardino campuses also has vehicles that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the all areas of both CSU San Bernardino campuses. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All CSU San Bernardino campus structures are at risk from severe weather. There are approximately 111 buildings at the main campus that could be damaged by wind, hail, and/or lightning. (Estimated facility costs at the Palm Desert campus are currently not
available.) If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $626,694,141 for 80 buildings, and are unknown for the remaining 31 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at both CSU San Bernardino campuses varies throughout the day. As of Fall, 2019, CSU San Bernardino had 20,311 students and 2,118 faculty and staff. All are at risk from severe weather events, with 22,429 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to both CSU San Bernardino campuses. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU San Bernardino.

It is evident that CSU San Bernardino has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection

218 Retrieved on 07.19.2021 from https://www2.calstate.edu/csualumni/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx
services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
19.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU CAMPUS campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
Table 19-36: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>

<td>N/A</td>
</tr>
</tbody>
</table>
| Which population groups have little/limited support networks if impacted by an event? | • International students  
  • Students experiencing homelessness  
  • Populations from outside the region |

**Resilience Variables Related to Campus Emergency Management**

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**
In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Given a large-scale event, students would need a lot of Health and Wellness help. They would have a large portion of students who would reach out. Currently have one appendix for the student health center, and a small portion should be expanded. “Would love to delve more into this more.” It is based on the on-campus resources, it is reflected there, but very minimally.
- Have a CERT team, and they participate in exercises.
- Communications is a high issue of concern because people don’t even know they need to get the coms piece, for when new students come to campus. There is vulnerability across the board. They have a communications annex, and
emergency messaging was honed during the PSPS. A lot came up in the audit and the challenge is how to address. The auditor asked them to address in different language. They would like to put priority in that effort. Worked well to go back, look at the planning shortfalls when less students to look at [the messages].

- International students are of concern because they are not aware of the systems that are in place and there is a language barrier. There is a small accounting for this in the plan.
- Immigrants/immigration status issues (undocumented, DACA, etc.) is a definite issue of concern. It is “big on the campus.” would be great to have outreach to the groups and have resources. Developing plan is in process and it would be great to have plans and resources. There is not have enough manpower for all of these groups to having them knowing it is there and it is a shortfall of being able to get out there. While it is not a politically charged campus by nature (“not enough of me to go around – that is our downfall”) “What if the student doesn’t know, where do I go? Am I going to have to stop going to school?” They don’t know the resources.
- The LGBTQI population is of concern for them knowing what is out there; what they will need and what can be provided. If they must evacuate campus, “that is going to be a rough time / in a shelter / letting them know if that resource is there.” The auditor required them to have a line about some of the groups but not yet addressed.
- LGBTQI and DACA fall down the most – would be best of those two groups.
- Transportation dependency is an issue of concern and they are in the processes of addressing this as a planning issue. Started meeting with local school bus to put a contract into place to provide assistance to move off the campus but question is where to move them to? Senior administration doesn’t understand a block of room can’t be kept. Started planning and there are a lot of pieces to it.
- The power outages have been a “blessing in disguise” [for issue planning].

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.
Table 19-38: CSU San Bernardino *Highly Likely, Likely and Possible* Hazards

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\(^{220}\) Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\(^{221}\) Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to

water quality issues due to loss of drinking water, increased fire danger that leads to
drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat
events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on
social stability for all populations. In addition to the physical impact exposure during a
no-notice earthquake event and the social and logistical challenges of a recovering
community, an earthquake can have lasting impacts long afterwards due to post
traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet
scientifically realistic earthquake sequence that is being used to better understand
hazards for the San Francisco Bay region during and after a magnitude-7 earthquake
(mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk
populations located in areas of concentrated damage are anticipated to experience longer
recovery trajectories, increased long term housing displacement, and transportation
impacts due to dependencies on transit dependencies. When neighborhood schools
close, families with school age children may move to other areas to keep their children in
schools. Persons with access and functions needs are likely to be more dependent on
access to functioning medical, social and personal health care services that would be
overwhelmed by the event and therefore increasing their vulnerabilities. For the
homeless populations, the loss of social community services and damages to shelters
could add to protracted relocations. For the young and mobile populations who rent, the
major disruption to housing, jobs and transit will also drive relocation. Widespread
housing damage and preexisting housing market constraints will make it “extremely
challenging” for the socially and economically vulnerable populations to find alternative
housing near their home communities. Those who utilize interim and irregular housing
for months and years after a disaster are more vulnerable to physical, social, and mental
disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks
and post disaster conditions delay population return and increase outmigration.

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability
to these events and their impacts depends on human behavior and the traditional social
factors such as situational awareness, prior knowledge of hazards, social capital and

---

https://doi.org/10.3133/sir20175013v3, accessed 0162021
decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutants, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitoes that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme cases, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has
been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 223

**Hazardous Materials**

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for

---

environmental disease. Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.

**Landslides**

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied buildings which makes it a function of structural vulnerability and therefore, indirect. The degree of vulnerability to landslides by an individual considered at high risk, or even the general populations, also depends on human behavior, including many of the traditional social factors that are difficult to measure such as situational awareness, prior knowledge of hazards, and decision-making capabilities.

Landslides can result in primary lifeline failures through the loss of roads or power and communication lines. Transportation routes are often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods. Risk from landslide relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk.

---

224 [https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/](https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/)

Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.

---

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

20.1 University Profile

University History

San Diego State University (SDSU) is the oldest higher education institution in San Diego. SDSU was founded on March 13, 1897. San Diego State was originally known as the San Diego Normal School, where they provided training and education for school teachers. In 1921, the name changed to the San Diego State Teachers College and eventually unified with the San Diego Junior College campus. That union would only last through 1946. In 1931, the campus relocated to the Mission-Revival style genre buildings. Today that area is known as the Main Quad. In 1960, San Diego Teachers College would eventually join the California State University System. By 1971, the university would change its name to San Diego State University.

SDSU is designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

San Diego State University (SDSU) operates under a shared governance philosophy — where each member of the community (whether faculty, student, staff, or administrator) has an opportunity to weigh in on matters of policy and procedure. SDSU’s governing bodies include the Office of the President, the University Senate, and Associated Students.

The University Senate considers a wide range of issues like, policies with respect to the general welfare of the University, educational policy, the selection of administrative personnel, maintain adequate communication within the University community, appoint University Senate Committees and the ultimate authority to recommend approval of candidates for graduation.

University Mission

“The mission of San Diego State University is to provide research-oriented, high-quality education for undergraduate and graduate students and to contribute to the solution of problems through excellence and distinction in teaching, research, and service. The university strives to impart an appreciation and broad understanding of the human
experience throughout the world and the ages. This education extends to diverse cultural legacies and accomplishments in many areas, such as the arts and technology; the advancement of human thought including philosophy and science; the development of economic, political, and social institutions; and the physical and biological evolution of humans and their environment. San Diego State University pursues its mission through its many diverse departments and interdisciplinary programs in the creative and performing arts, the humanities, the sciences, and the social and behavioral sciences.”

University Location

SDSU is located in San Diego, CA, the second largest city in the state. San Diego has miles of sandy beaches along the Pacific Ocean and a short drive to the international border to Mexico. San Diego State is located in the mid-city region of San Diego

University Population

San Diego State’s population exceeded 33,000 with an overwhelming population of undergraduates making up 78% of the student population. White students make up 34.6% of the student population with Latinos second in population with 28.1%.

20.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an]
estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate ..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

20.3 Hazard Identification and Risk Assessment

Overview of San Diego State University History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 20-1 (following).

Table 20-1: Hazard Identification Determinations

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely**- 76%-100% that the hazard would occur annually.
- **Likely**- 50%-75% that the hazard would occur annually.
- **Possible**- 11%-49% that the hazard would occur each annually.
- **Unlikely**- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

1. Travel through the air, such as tuberculosis, measles, or COVID-19;
2. Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
3. Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
4. Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 20-2 below.)

**Descriptions of Identified Communicable Disease Hazards at San Diego State University**

San Diego State University (SDSU) has identified three (3) communicable disease hazards that have had the greatest impact on campus – COVID-19, Meningitis, and Mumps. The following are brief descriptions of the communicable disease hazards at SDSU.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It’s not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.  

**Meningitis**

Meningitis is an inflammation of the fluid and membranes (meninges) surrounding the brain and spinal cord. The swelling from meningitis typically triggers signs and symptoms such as headache, fever and a stiff neck. Early meningitis symptoms may mimic the flu (influenza). Symptoms may develop over several hours or over a few days.

Most cases of meningitis in the United States are caused by a viral infection, but bacterial, parasitic and fungal infections are other causes. Some cases of meningitis improve without treatment in a few weeks. Others can be life-threatening and require emergency antibiotic treatment. Bacterial meningitis is particularly serious and can be fatal within days without prompt antibiotic treatment. Delayed treatment also increases the risk of permanent brain damage or death. 

**Mumps**

Mumps is a viral infection that primarily affects saliva-producing (salivary) glands that are located near the ears. Mumps can cause swelling in one or both of these glands, and is

---

contracted by breathing in saliva droplets from an infected person who has just sneezed or coughed. Mumps can also be contracted from sharing utensils or cups with someone who has mumps.

Complications of mumps, such as hearing loss, are potentially serious but rare. There's no specific treatment for mumps.

Mumps outbreaks far less common than they used to be, but can affect people who aren't vaccinated – especially in close-contact settings such as schools or college campuses.⁷

Location of the Hazard

Communicable diseases have the potential to affect the entire San Diego State University (SDSU) planning area equally. As a result, the communicable disease hazard can be found at the SDSU main campus located in San Diego, CA (San Diego County). The communicable disease hazard can also be found at the Brawley, CA and Calexico, CA (Imperial County) sites of the SDSU-Imperial Valley satellite campus.⁸ Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) three (3) SDSU locations are at risk of exposure to the communicable disease hazard.

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For SDSU, approximately 15% of its 35,081 enrolled students (or 5,262 students) reside in student housing.⁹,¹⁰

---

¹⁰ California State University. CSU Campus Match. Retrieved 04.30.2021 from: https://www2.calstate.edu/attend/campuses/campus-match/Pages/campus-match.aspx
Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 20-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

Figure 20-1: Biosafety Levels (BSLs)

The Extent of San Diego State University (SDSU) Communicable Disease Hazards Except COVID-19:

---

Before the COVID-19 pandemic, there were cases of Meningitis and Mumps at San Diego State University (SDSU). Measles would be classified at the BSL-2 containment level, and Mumps would also be classified at the BSL-2 containment level.  

**The Extent of San Diego State University (SDSU) COVID-19 Communicable Disease Hazard:**

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.

**History of the Hazard**

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 121 cases of COVID-19 at SDSU. Each CSU campus is an integral part of the surrounding community. Any event that occurs on a CSU campus has an effect on both the adjacent areas of campus and on the community-at-large – and vice-versa. Communicable disease hazard events are no exception. Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 20-5, 20-6, and 20-7 show campus-level and County-level COVID-19 case data for San Diego State (SDSU). These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

## Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the SDSU campus. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of SDSU students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already

---

occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including SDSU) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 20-7: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 20-9 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall into these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 20-8: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one’s hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

### RG 3

<table>
<thead>
<tr>
<th>Anthrax</th>
</tr>
</thead>
<tbody>
<tr>
<td>West Nile Virus</td>
</tr>
<tr>
<td>SARS Virus (Including COVID-19)</td>
</tr>
<tr>
<td>Tuberculosis</td>
</tr>
<tr>
<td>Typhus</td>
</tr>
<tr>
<td>Yellow Fever</td>
</tr>
<tr>
<td>Hantaviruses</td>
</tr>
<tr>
<td>Avian Flu</td>
</tr>
</tbody>
</table>

These bacteria and viruses cause severe to fatal
disease in human, but vaccines or other
treatments do exist to combat them. Laboratory
personnel have specific training in handling
pathogenic and potentially lethal agents and are
supervised by competent scientists who are
experienced in working with these agents. This is
considered a neutral or warm zone.

### RG 4

<table>
<thead>
<tr>
<th>H5N1 (Bird Flu)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dengue Hemorrhagic Fever</td>
</tr>
<tr>
<td>Marburg Virus</td>
</tr>
<tr>
<td>Ebola Virus</td>
</tr>
<tr>
<td>Smallpox</td>
</tr>
<tr>
<td>Lassa Fever</td>
</tr>
<tr>
<td>Crimean-Congo Hemorrhagic Fever</td>
</tr>
<tr>
<td>Other Hemorrhagic Diseases</td>
</tr>
</tbody>
</table>

These viruses and bacteria cause severe to fatal
disease in humans, for which vaccines or other
treatments are *not* available. When dealing with
biological hazards at this level the use of a Hazmat
suit and a self-contained oxygen supply is
mandatory. The entrance and exit of a BSL-4 lab
will contain multiple showers, a vacuum room, an
ultraviolet light room, autonomous detection
system, and other safety precautions designed to
destroy all traces of the biohazard. Multiple
airlocks are employed and are electronically
secured to prevent both doors opening at the
same time. All air and water service going to and
coming from a BSL-4 lab will undergo similar
decontamination procedures to eliminate the
possibility of an accidental release.

**Probability of Future Occurrence of the Hazard**

There are significant data limitations regarding non-COVID-19 communicable disease
cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it
is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19
communicable disease hazards. However, based on the limited data, it is feasible to
present qualitative probabilities of future occurrence based on ranges of communicable
disease frequency. Table 20-10 shows a probability scale of future occurrence for the nine
(9) communicable disease hazards profiled in this assessment. This scale is divided into
four (4) levels of probability:
Table 20-9: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence. Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the SDSU campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, the CSU System had 480,541 students and 53,763 faculty and staff.) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic on the SDSU campus.

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including SDSU) are at risk of developing an extreme incidence of COVID-19,

20 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

21 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 20-2 below for the economic impact to the campus.) Several CSU campuses saw refund losses surpass $10 million. (See Table Figure 20-2.)

Figure 20-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs

![Figure 20-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs](image)

**Mitigative Relief from Federal Assistance**

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table CD.10) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

</table>
Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. *If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.*

See Table 20-13 below for the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

Table 20-12: Scenario of Communicable Disease Hazard Affecting 10% of the CSU Population.

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system (including San Diego State). In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Dam and Levee Failure**

**Description of the Hazard**

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water.
into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtopping to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

**Location of the Hazard**

San Diego County is home to a number of flood control facilities mostly located at the base of the hills and mountains of the county. There are few levee systems mostly in the coastal plains and valleys region including along the San Diego River and the south county. The San Diego River drains the mountains east of San Diego, San Vincente Reservoir, and El Capitan Reservoir. Levees have been constructed to protect the banks of

the San Diego River downstream past where the channel extends past the campus. Levees are also used in containment of flood channels in areas of level topography on the valley floor. The levees that line the San Diego River are located downstream from the campus. In short, there are no levees in the area of San Diego State University campus and the campus is not located within a designated levee protected zone identified in the National Levee Database30.

The primary hazard dam for the San Diego State University (SDSU) campus is Murray Dam located 1 ½ miles east of the campus. The dam feeds the Chaparral Creek which passes by the campus. The campus is elevated on a bluff from the river valley. The campus does have parking lot 16, parking lot 17, Building A, the SDSU Garage, and Villa Alvarado Residences that are located on the valley floor within the dam inundation zone for Murray Dam.

The San Diego River is a seasonal river providing flood control and drainage that extends through populated areas. The river feeds into the Pacific Ocean after extending 30 miles through San Diego County. The San Vicente Reservoir and El Capitan Reservoir feed into the San Diego River. The river is an unregulated channel from the dams to the ocean. The San Diego State University campus is situated higher in elevation on a hillside from the San Diego River channel. The distance from the river to the campus boundary is just over a half of a mile.
Figure 20-4: Murray Dam Breach Inundation Map

Figure 20-5: El Capitan Dam Breach Inundation Map
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- High hazard potential dams may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- Significant hazard potential dams are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- Low hazard potential dams are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

The San Diego State University campus lies outside of the inundation zone of the dams listed above with the exception of the facilities located in the lower elevations of the valley floor next to Interstate 8. In the event of a catastrophic failure of the identified dams, most of the San Diego State University campus is expected to remain out of the inundation area. The inundation area is expected to spread water across the Chaparral Creek valley floor including across Interstate 8. There are multiple transportation corridors that lie within the dam inundation zones that could compromise transportation routes and areas the campus community reside or work. Based on the above factors, the planning committee ranks the extent of the hazard as Low to Moderate.

**Extent – Levee Failure**

The levees that line the San Diego River are located downstream from the campus. In short, there are no levees in the area of San Diego State University campus and the campus is not located within a designated levee protected zone. Based on these factors, the planning committee ranks the extent of the hazard as Low.

**History of the Hazard**

There are no records of dam or levee failures in areas that present a threat to the San Diego State University campus. Additionally, there have been no occurrences of dam failure threatening the Imperial Valley Campus in Imperial County. San Diego County has experienced the following dam failures:

**Potential Impacts of the Hazard**

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those

---

experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Villa Alvarado Residence Halls flooding and damages
- Displaced residents from residence halls
- Loss of property contents
- Infrastructure damage
- Flooding to Building A and SDSU Garage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

Probability of Future Occurrence of the Hazard

San Diego County is determined to be at risk from dam and levee failure in many parts of the county. The location of the San Diego State University campus is downstream 1.4 miles to the southeast of the Murray Dam and Reservoir but elevated by 100-150 feet on a bluff overlooking the San Diego River channel demonstrating that the remote potential exists for future dam or levee related issues. However, the dam inundation zone does include lower elevation sites: the Villa Alvarado Residence Hall complex, parking lot 17, parking lot 16, and central receiving. There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on historical experience and occurrences, the likelihood of this hazard is low.

The San Diego State University, Imperial Valley campus is not within proximity to any dams nor within any dam inundation zone. There are no identified levees in proximity to the Imperial Valley campus and thus the campus is outside of any levee protected zone. The probability of future occurrence for both dam and levee failures is Unlikely.

Vulnerability to the Hazard

The San Diego State University campus is subject to the potential effects of flooding resulting from compromised dams and levees. The effects of dam failure would likely be indirect affecting members of the campus community and regional transportation networks and services. Some flood control channels are lined by levees intended to protect the surrounding areas from rises in water level. In the case of dam failure, the amount of time to respond to the needs of the campus community prior to inundation will be limited.

The most significant challenge regarding dam failures is they generally result in catastrophic outcomes. Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations.
These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of flood insurance will cause extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the San Diego State University campus will vary depending on when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $726,584,983. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at San Diego State.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the San Diego State campuses, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. The consequences of a dam failure would generate catastrophic results to
downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.
**Drought**

**Description of the Hazard**

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought focus** is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for San Diego State University (SDSU)) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified in San Diego County and the City which surround the SDSU campus. Drought is not a location-specific hazard and affects the entire campus planning area equally. Drought location is not isolated to the campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years. ³³

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout the region, county and city surrounding the planning area, and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire CSU 23-campus system, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically or potentially impacted by drought within each jurisdiction.

In addition, drought-related land subsidence has occurred throughout the state and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels in California have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Though such effects have not been reported on campus, they remain issues of concern for the campus over the long term.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

Although the campus planning team identifies the extent of the hazard as Low (qualitatively) which corresponds to D0 – D1 on the Extent scale (below), San Diego County has experienced more severe drought conditions for 15 of the past 20 years, including 5 years of D4 levels. As such, the campus planning team recognizes that while historic impacts shaping the extent of drought on campus have been minimal, the potential impacts are tied to trends across larger geographic areas, and, therefore, the committee recognizes that the extent of drought on campus has the potential to increase in the future.

curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor;

History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous, including San Diego County, and the city of San Diego which includes the SDSU footprint. Although no drought occurrences have been reported specifically for the campus, according to the US Drought Monitor, Time Series data, San Diego County has experienced 6 periods of drought between 2000 and 2021, encompassing 15 of the last 20 years, including the most severe and prolonged drought from 2012 – 2020.

Figure 20-7: Periods of Drought in San Diego County, California, 2000 – 2021

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been in effect in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the SDSU campus planning area:

Note: San Diego County experienced drought for 3 additional years (2012 – 2020).

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state's agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal’. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.  

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and

regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the SDSU campus planning area is a potential reduction in water availability for the municipal area tied to each campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of SDSU to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of any agricultural research crops and/or field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. 39 However, the wildfire hazard is analyzed separately in this plan. (See below for coverage of the wildfire hazard).

In reviewing the occurrences of drought for San Diego County and the City, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to SDSU, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campus. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus; however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs

20-43
such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area. ⁴⁰

At present, drought related damage to campus buildings and infrastructure at SDSU has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for SDSU is ultimately tied to broader interdependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including SDSU. A reduction of electric power generation and water quality deterioration are also potential impact factors.

</table>

### Hydropower
- **Type**: Indirect
- **Impact**: Decreased summer flows resulting from earlier snowmelt and a shift in peak runoff could affect hydropower generation during summer months

### Precipitation
- **Type**: Direct
- **Impact**: Warmer winter temperatures will result in a greater percentage of precipitation falling as rain rather than as snow

### Groundwater
- **Type**: Indirect
- **Impact**: Reduction in snowpack and extended periods of drought are likely to increase dependency on groundwater

---

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) state-wide indicates that some degree of drought has nearly a 100% probability of occurrence in the state in any given year. Given that SDSU lies within a drought impacted region, as made evident by the Time Series data for the county, it is prudent to extend this likelihood of occurrence to the planning area.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the SDSU campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the SDSU planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water.
for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

**Vulnerability of Populations**

Drought vulnerabilities on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerability measures apply to the students, faculty and staff of the SDSU campus.

**Property Vulnerability**

Drought vulnerabilities for property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the SDSU campus.

**Natural Environment Vulnerability**

Drought vulnerabilities for the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping the impact of drought throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS

---

led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought impacts to state and SDSU’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of San Diego and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

Fault Rupture – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

Liquefaction – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

Subsidence - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local
environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

Location of the Hazard

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. San Diego State University is located in central San Diego east of Mission Valley. In general, fault systems surround and traverse through San Diego County including the area of San Diego State University. Throughout the valleys the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 85-90 miles east of the San Diego State University campus. In addition to the San Andreas Fault, San Diego County is home to or near additional fault systems with the potential to generate strong ground shaking. The Elsinore Fault extends across the northern portions of the county in a southeast to northwest direction 35 miles northwest of the campus. The Rose Canyon Fault is another southeast to northwest fault 7-8 miles west of the campus traversing through downtown San Diego then paralleling the coastline. The Coronado Bank Fault extends offshore approximately 20-25 miles west of the campus. There are numerous additional faults in the area on all sides of the campus.

The Calexico campus is located in proximity to a number of active faults capable of producing strong earthquake. The campus is 7 miles west of the Imperial Fault. The Cerro Prieto Fault is 7 miles southwest of the Calexico campus in Mexico. The Superstition Hills Fault is 12 miles north of the campus. The campus is 12 miles south of the Brawley Fault which extends through the Salton Sea to the San Andreas Fault. The San Andreas Fault is 50 miles north of the campus and extend to the northeast towards Palm Springs.
The San Diego State University campus does not reside within areas designated to be liquefaction zones. However, substantial areas of the community surrounding the campus reside within the liquefaction zones including access routes into and out of the campus. These zones are mostly following the creek channels including the San Diego River and Mission Valley. The affected transportation corridors include Interstate 8, Interstate 15, College Avenue, and San Diego Metropolitan Transit Light Rail. The liquefaction zone generally follows the Mission Valley floor.

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity, and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and
evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

<td></td>
</tr>
</tbody>
</table>

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.
San Diego State is surrounded by liquefaction zones. In addition, powerful fault systems traverse and surround the campus, and the area has experienced numerous powerful and damaging events, though no major damages have been recorded since the 1979 Imperial Valley event. That said, the potential for severe impacts remains. The impacts of a major earthquake would be felt beyond the campus and have long reaching effects. The risk of casualties and damages would likely extend to the homes and workplaces of members of the campus community including students, staff, and faculty. As such, the planning committee ranks the extent of the hazard as Moderate.

History of the Hazard

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. San Diego County also has a long history of earthquake activity. The entire area of San Diego County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The May 18, 1940 Imperial Valley Earthquake became the largest seismic event in the Imperial Valley at the time. The Imperial Valley Earthquake resulted in 8 people being killed, multiple injuries, and $6 million in damages. The earthquake caused extensive damage to structures, the transportation infrastructure, utility systems, irrigation systems, and critical facilities. The Imperial Fault displayed a surface rupture extending of at least 25 miles. The earthquake was felt as far away as Los Angeles and Tucson.

The April 8, 1968 Borrego Mountain Earthquake shook a large part of southern California. The earthquake caused extensive damage across southern California. The earthquake resulted in extensive infrastructure damages, power lines being severed, roadway damages, and structural damages. Ground displacement was found along the Superstition Hills Fault miles from the epicenter. The earthquake was felt as far away as Yosemite Valley, Fresno, and Las Vegas.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils to the north of the campus along the San Diego River presents a potential for liquefaction creating greater ground instability during seismic events. Major transportation routes servicing the campus exist in these areas. A major earthquake in the San Diego area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

---

46 San Diego County Multi-Jurisdictional Hazard Mitigation Plan, October, 2017
Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near San Diego could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near San Diego could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader San Diego County region limiting immediate assistance that the campus may normally expect.

Local impacts to San Diego State University campus caused by an earthquake could include:

- Damage and secondary fires to industrial buildings to the west of campus
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway and road system
- Damage to underground transit
- Structural damage to bridges
- Landslides to hills on north side of campus
- Physical Plant located on hillside
- Potential liquefaction damage to areas near the San Diego River and Alvarado Creek
- Potential isolation among on-campus residents
- Structural damage to flood control and drainage systems
- Damage to the Lake Murray Dam
- Structural damage to campus academic and support buildings
- Structural damage to parking structure
- Structural damage to residence halls resulting in displaced student populations
- Potential isolation among on-campus residents
- Structural damage to nearby residences and apartment complexes
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

**Probability of Future Occurrence of the Hazard**

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the San Diego County fault systems surrounding San Diego is included in the following table.

</tbody>
</table>

Based on the earthquake shaking potential in the San Diego County region, the proximity to the above listed fault systems, the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of San Diego State University places the campus in a suburban community near residential, commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to San Diego generally surround the city and some cross into the city including near the San Diego State University campus. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected.

Elements of the vulnerability to a major earthquake on the San Diego State University campus will vary depending on when the earthquake were to strike. The primary basis of

---

47 San Diego County Multi-Jurisdictional Hazard Mitigation Plan, October 2017

48 Southern California Earthquake Center, Earthquake Information, https://scedc.caltech.edu/earthquake/faults.html#I

vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the area. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. As the San Diego State University campus is downstream from dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $726,584,983.

*Buildings with no value defined are also included in the respective Zones they are found in.

The table above includes 14 facilities located at the Calexico based San Diego State University, Imperial Valley campus. The provided cost estimates for the Imperial Valley campus includes $18,144,214. However, 12 facilities do not have costs included.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater San Diego and Imperial County regions and the San Diego State University campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the San Diego State University campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding San Diego, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader San Diego County region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population is additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are
magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

---

**Erosion**

**Description of the Hazard**

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.”\(^{50}\) Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

**Location of the Hazard**

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While coastal erosion can happen in any storm, it is more likely during El Nino events, which occur every 5-7 years. For the purpose of this campus-level analysis, the erosion hazard poses an equal risk across the terrain of the SDSU campus.

Other incidents of erosion, such as occurs around buildings, is relatively non-spatial and can occur in any locations with conducive soil structure and a source of movement, such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. An effort to identify specific erosion prone locations on campus has not been conducted, but campus leadership may consider doing so in the future.

---

Extent of the Hazard

Erosion is occurring on the Pacific coastline west of San Diego State University (SDSU). While there is no published scale of severity or extent for this geologic hazard on the SDSU campus, erosion is likely to occur if conditions are favorable. As such, for the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the SDSU campus with erosion-prone characteristics. No erosion locations have been identified on campus, and no history of erosion is present on campus. As such, the planning committee ranks the extent of the hazard as **Low**.

History of the Hazard

Coastal cliff erosion has been ongoing in San Diego. In 2000, a woman was killed by a coastal landslide in Encinitas, caused by eroded and unstable cliffs. However, there have been no recorded incidences of erosion on the SDSU campus.

Potential Impacts of the Hazard

Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. As a result, and in consideration of the potential extent of erosion, the probability of at least a limited degree of erosion occurring somewhere on the campus in the future is **High** over the long term.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. SDSU infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. CSU leadership would consider performing an analysis to identify such at-risk buildings, infrastructure, slopes and soil types in the future.

In the wider San Diego community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.
Vulnerability Assessment Conclusions

While the ability to predict future erosion on the SDSU campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

Description of the Hazard

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.\(^5^1\)

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.\(^5^2\) As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.\(^5^3\)

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.\(^5^4\) In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor

\(^5^3\) Ibid.

workers, low-income households, and individuals with certain chronic medical conditions.  

**Location of the Hazard**

Extreme heat events are a non-spatial hazard and may occur throughout the San Diego State campus.

**Extent of the Hazard**

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the low 70s to the high 70s in San Diego. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at the San Diego International Airport was 100° F. This high temperature was even more unusual considering that the airport thermometer usually benefits from a sea breeze.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach those criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur. Given the frequent occurrence of excessive heat events over the last 13 years along with the related vulnerabilities, the planning committee ranks the extent of the hazard as **Moderate**.

Figure 20-11 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

---

56 The San Diego Union Tribune. *Sunday’s Temperatures Ranged from 100 in San Diego to 122 in Borrego Springs*. Print. Retrieved 01.29.21 from: https://www.sandiegouniontribune.com/weather/story/2020-09-06/the-temperature-is-currently-100-or-higher-from-san-diego-to-borrego-springs

As the heat index rises, so does the potential danger to people and animals. Table 2-23 (following) shows the health hazards associated with extreme heat.

Total # of Events: 4  Total # of Events: 4  Total # of Events: 21

Potential Impacts of the Hazard

San Diego State may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air
conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

Extreme heat events have occurred annually in San Diego for the past three years, with an average of over 2 events per year over the last 13 years. It is Highly Likely that the hazard will occur annually.

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.59 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

San Diego State is aware of the potential for extreme heat events, particularly for its satellite campus in the Imperial Valley, where the potential for extreme heat events is even greater. In the Imperial Valley, summertime temperatures can reach well into the 100s. However, Imperial Valley is not a residential campus, so the university is not responsible for providing 24/7 access to air-conditioned housing. The campus also has contingency plans in place for providing water to the campus community during excessive heat events.

San Diego State is susceptible to power/utility outages that could affect their ability to air-condition buildings and facilities. While they are not at risk for public safety power shut-offs, they have experienced localized outages and have had to bring in portable toilets, lighting, and transportation assistance to residence halls. The campus has also closed and/or canceled classes due to outages.

The campus experiences heat events regularly. With the potential for longer-lasting and more frequent heat waves, the campus may want to consider additional strategies for handling the risks and vulnerabilities.

**Estimate of Potential Losses**

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

**Vulnerability Assessment Conclusions**

While the ability to predict future heat events at the San Diego State campuses is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.\(^\text{60}\)

**Identified Data Limitations**

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

---

**Flood**

**Description of the Hazard**

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding represents one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other features may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater
amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric Rivers**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California, they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.

Figure 20-12: Introduction to Atmospheric Rivers

---

Location of the Hazard

San Diego is located at the southwestern corner of the state. San Diego is comprised of a diverse geography including coastline, dense urban areas, suburban neighborhoods, heavy industry, and vegetation filled valleys. Along the northern edges of San Diego State University campus are a series of ravines filled with dense vegetation. These ravines drain the bluff that the campus sits on into the San Diego River Valley below. There are a number of flood control reservoirs and flood control channels upstream from the San Diego State University campus that contribute to the potential for flooding in the lower portions of the campus. The area surrounding the campus is a combination of developed suburban environments predominately consisting of residential and commercial land uses and open hillsides. The San Diego State University campus is entirely located in a designated Zone X: Area of Minimal Flood Hazard with the exception of the lower parking areas. The lower elevations areas of the campus are found in Zone AE: 1% Annual Chance Flood Hazard.
The San Diego State University campus is located ¼ mile south of the Chaparral Creek that flows from Lake Murray into the San Diego River through Mission Valley towards the ocean. The Chaparral Creek and San Diego River receive the majority of their water from precipitation during the winter months. The Chaparral Creek does not contribute to a direct flood hazard to the campus except for the facilities in the lower sections of the campus and may also compromise access routes to the campus. The Lake Murray drainage extends to the west towards the ocean.

Extent of the Hazard

The San Diego State University campus is entirely located in a designated Zone X: Area of Minimal Flood Hazard with the exception of the lower parking areas. The lower elevations areas of the campus are found in Zone AE: 1% Annual Chance Flood Hazard. The access routes into and out of the campus are found in areas primarily designated as Zone X: Area of Minimal Flood Hazard, however the portion of Interstate 8 immediately north of the campus is designated as Zone X: 0.2% Annual Chance Flood Hazard. The San Diego State University, Imperial Valley Campus is entirely located in a designated Zone X:
Area of Minimal Flood Hazard as are all access routes into and out of the campus. Based on the campus mostly being located in Zon X, but also with isolated ponding occurring in low lying areas (Zone AE) where a residence halls and parking lots are located, the planning committee ranks the extent of the hazard as **Low to Moderate**.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

**Table 20-23: Flood Zone Designations and Descriptions**

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised map in place of Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, BFEs derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
</tbody>
</table>
Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.

Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.

Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.

Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.

History of the Hazard

Flooding in San Diego and the broader San Diego County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the San Diego State University campus. Records of specific flood events on campus are not available, but reports from staff indicate that isolated ponding occurs in low lying areas during heavy rainfall events.

**Potential Impacts of the Hazard**

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Inability for campus operations to resume
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

San Diego County is determined to have considerable portions of the county to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common in the San Diego area with winter storms that are saturated with subtropical moisture. The area surrounding the San Diego State University campus does not generally promote conditions for flood waters to accumulate. The majority of the campus is elevated on a bluff. However, portions of the campus in the valley floor such as the Villa Alvarado Residence Hall complex, parking lot 17, parking lot 16, and central receiving are all located within the Zone AE Special Flood Hazard Area (Area Inundated by 1% Annual Chance of Flooding). There are specific buildings and areas of the campus located in Zone AE have a greater risk for isolated flooding. The remainder of the campus is located within a Zone X (Area of Minimal Flood Hazard). However, there is a historic record of isolated urban or street flood events provides a demonstration of potential flood activity.

The probability of future occurrence for flooding on campus is **Unlikely** in Zone X locations, but **Possible** in Zone AE areas.

Vulnerability to the Hazard

The San Diego State University campus is subject to the effects of isolated flooding and ponding resulting primarily from excessive precipitation and isolated strong storms. There is a more remote potential for flooding and damage on campus due to overflow or damage to flood control systems. The channels and extending irrigation channels that surround the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems, especially those assets (residence hall, parking lots and central receiving) located in Zone AE.

Vulnerability to flooding on the San Diego State University campus will vary depending on when the flood were to occur. The risk to the campus population will be lessened
during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community may become trapped on campus depending on the level and location of isolated flooding occurring on surface streets, especially those persons working or residing in Zone AE assets. However, in rare, region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

San Diego State University is in proximity to a variety of industrial and commercial facilities in the surrounding communities. When these facilities are inundated with flood water, the potential for chemical release exists presenting possible exposures to individuals from the campus community. These facilities additionally line many of the primary access routes in and out of the campus.

The campus sits on land that is elevated on a bluff overlooking ravines that are situated behind the university limiting the effects of widespread flooding. During low probability, severe flood events, some campus buildings and infrastructure might be vulnerable to localized flooding if it reaches the university, especially Zone AE assets. Campus utilities and communication capabilities might be impacted by flood waters rendering them disabled. A flood covering a large portion of the city would likely affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. Flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in
the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $726,584,983. However, it is unlikely for flood to cause destructive losses to the entire campus.

*Buildings with no value defined are also included in the respective Zones they are found in.

The table above includes 14 facilities located at the Calexico based San Diego State University, Imperial Valley campus. The provided cost estimates for the Imperial Valley campus includes $18,144,214. However, 12 facilities do not have costs included.

Vulnerability Assessment Conclusions

While the campus is mostly located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in Zone AE exposed to mostly localized flooding and ponding from overflow of campus creeks or isolated or large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods.

The proximity to the San Diego River and Chaparral Creek further presents an additional risk factor for the campus.

The potential for unlikely but severe flooding on campus generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.
Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

Hazardous Materials

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

Fixed Hazardous Materials Incident: A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

Transportation Hazardous Materials Incident: A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

Pipeline Incident: A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and

maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness

**Natural-Technological Incidents (Natechs)**: During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. Please refer to Annex ? for the map identifying the types and locations of hazardous materials and infrastructure on or near the SDSU campus. The planning committee indicates that chemicals are located in science labs on campus, and possibly some stored chemicals elsewhere. Mapping indicates that a gas line comes into the campus from the main line. Otherwise, no

---

hazardous materials or infrastructure is located near campus. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city and county of San Diego, and reflect different types, configurations and scales dispersed across these geographic areas.

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

For the SDSU planning committee, chemicals are managed in campus science labs, and no events have taken place on campus. A rail line and a gas pipeline are about one mile north and south of campus, and chemical sites and hazardous waste sites are further away from the campus. Based on these factors, the extent of the hazard for the SDSU campus is Low, but to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20, 2021 a total of 2,096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

According to the campus planning committee, no events have taken place on campus.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type

of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also to some degree apply to the students, staff and environment on the SDSU campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazards (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including SDSU) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks,

---

manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the SDSU campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low - the campus has not experienced a hazmat event on campus. In addition, hazardous materials and infrastructure are a mile or more away which may slightly increase vulnerability and the probability of a campus-related event. Moreover, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the SDSU campus. As identified by the campus planning committee and on the hazmat map (see section X), the following vulnerabilities are present on campus: chemicals are managed in campus science labs. A rail line and a gas pipeline are about one mile north and south of campus, and chemical sites and hazardous waste sites are further away from the campus. Gases and chemicals or hazardous waste, if spilled or released, could impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the SDSU leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area
has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including SDSU) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the San Diego County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the SDSU campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The SDSU planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
**Landslide**

**Description of the Hazard**

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure.\(^1\) These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow.\(^2\) These landslides may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak

material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 20-15. Based on the Figure below, the campus appears to be adjacent or possibly connected to areas susceptible to landslide.

Figure 20-14: Deep-seated Landslide Susceptibility

Extant of the Hazard

Landslide risk in San Diego County is concentrated along canyons near the coastal areas with steep slopes. Landslides also occur throughout the western portion of the County and in the mountains to the east. Mitigation measures have stabilized many but not all landslides in urban areas. The indirect impacts of landslides in the region may cover a larger geographical extent than that of direct impacts. Based on the campus’ close proximity to a moderately susceptible landslide zone, and the history of significant impacts in the county, the planning committee ranks the extent of the landslide hazard for the campus as **Moderate**.
History of the Hazard
FEMA has declared twelve major disasters involving landslides, mudslides, mud flows, or debris flows since 1978 in San Diego County. NOAA recorded twenty-nine debris flow events from 2003 to 2019. Several significant landslides have occurred proximal to the campus, including in Mission Gorge, Santee, and El Cajon. No landslides have occurred on or immediately adjacent to the campus.

Potential Impacts of the Hazard
San Diego State University (SDSU) may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard
Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in San Diego County and therefore are highly likely to occur in the future. Given the location of the campus adjacent to the landslide zone, and the occasional occurrence of landslides in the county, the planning committee ranks the probability of the landslide hazard in some way affecting the campus or campus access routes as Possible

Vulnerability to the Hazard
The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. The campus and/or its surrounding transportation
routes may be vulnerable to some degree. See the landslide location map with campus location adjacent to landslide severity zones identified.

Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to SDSU.

Vulnerability Assessment Conclusions

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the SDSU campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.13

Power Outage

Description of the Hazard

San Diego is one of California’s largest metropolitan cities and the nation’s fifth most populous city. It is also the home of San Diego State University (SDSU). The city is known for its mild year-round climate, natural deep-water harbor, extensive beaches and parks, long association with the United States Navy and Marine Corps, and recent emergence as a healthcare and biotechnology development center. San Diego County also borders the country of Mexico making it a crossing point for the shipment of international goods.

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly populated areas like San Diego without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.
A power outage event can interrupt day-to-day operations of the SDSU campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of SDSU student residents in on-campus housing would also be affected by a power outage on campus and in the area. Additionally, a severe outage to the city of San Diego or San Diego County would also directly affect the campus and the community.

Electric power disruptions and outages fall into two categories: intentional and unintentional. The four types of intentional disruptions are:

- **Planned:** Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- **Unscheduled:** Some intentional disruptions must be done "on the spot" in response to an emergency.
- **Demand-Side Management:** Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- **Load Shedding:** When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

**Location of the Hazard**

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.
Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as **Moderate**.

History of the Hazard

San Diego State reported experiencing power outages in recent years, especially those due to extreme weather events. The Mt. Laguna satellite campus lies in the area of Southern California Edison’s Public Safety Power Shut-off mitigation areas. PSPS efforts has led to the closure of campus, cancellation of classes and temporarily interrupting campus operations. Additionally, the campus can be affected for multiple days if high wind, extreme weather environments continue for multiple days.

The main campus is not susceptible to PSPS mitigation efforts but has experienced loss of power events. Failures on the main campus are due to localized outages creating an impact requiring a need to bring in lighting alternatives, port-a-potties, transports to resident halls, unscheduled dismissing classes, and campus activities.

The university has mitigation efforts in place for power outages by creating four electric substations and plant for regenerating power temporarily to the campus, as the efforts to return power capabilities to the campus continue.

Potential Impacts of the Hazard

Instructors, campus residents, staff, and administration rely on electricity for basic operations. During a widespread power failure, it may take anywhere from several hours to days to restore operations if a significant event occurs. Electrical power may be the
only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

**Climate Change and Energy Shortage**

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and San Diego) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City of San Diego and San Diego County experience such outages. As such, the probability ranking for the San Diego area is **Likely**. Since the San Diego State University campus has also recorded power outage events, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.
Vulnerability to the Hazard

Based on the data available, and in consideration of the increasing effects of climate change, the probability of future occurrences prompting intentional outages and creating unintentional power outages the hazard is high for the county in different areas but not specifically influencing the Cal State San Diego. Nonetheless, it would serve the campus to ensure to be able to mitigate and cope with an interruption to electrical power.

Although the campus has specific power outage protocols in place, an outage can impact the operations of the university depending on the severity of the outage. During daytime hours, the University may remain open and business and instructional operations will remain on-going to the maximum extent possible. It will be expected that the areas surrounding the campus, including streetlights, will have also experienced a blackout.

Estimate of Potential Losses

The data provided by Cal State San Diego State does not report any value for potential losses due to power outage.

Vulnerability Assessment Conclusions

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

Cal State San Diego did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
**Tsunami**

Description of the Hazard:

A tsunami is a wave triggered by any form of land displacement along the edge or bottom of an ocean or lake. Land displacement can be in the form of submarine landslides or submarine dip-slip faults. These types of faults cause ruptures that result in seafloor uplift or down-drop. This mass movement translates to a tsunami or gravity wave within the overlying water at the surface.

Tsunamis travel radially outward from the area of initiation. The size of a tsunami is proportional to the mass that moved to generate the tsunami. As a tsunami approaches the shore and the depth of the water column decreases, the energy in the wave pushes the wave crest above the water surface resulting in a larger wave height. Wave runup is the elevation above mean sea level on dry land that a tsunami reaches. Run-up is what causes inundation of coastal areas that are below the run-up height.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing severe damage to coastal development. At the shoreline, tsunamis may take the form of a fast-rising tide, a cresting wave, or a bore (a large, turbulent wall-like wave). The bore phenomenon resembles a step-like change in the water level that advances rapidly (from 10 to 60 miles per hour). The first wave is usually followed by several larger and more destructive waves.

Location of the Hazard:

According to the 2018 CA State Hazard Mitigation Plan, tsunami locations span 94 incorporated communities and 83 unincorporated areas across 20 coastal counties.

As identified on the Tsunami Inundation Area map (below), San Diego County is at risk to the tsunami hazard, although the San Diego State University campus is located away from the tsunami inundation zone. However, due to its role in the community, the campus conducts tsunami warnings due to the potential impact of tsunami to transportation routes utilized by staff and students.
Extent of the Hazard

The factors shaping the extent or severity of the hazard are a combination of geophysical forces (the amount of vertical and horizontal motion of the sea floor, the area over which it occurs, and the efficiency with which energy is transferred from the earth’s crust to the ocean water) and the geographic range of coastal development to be impacted.

More specifically, as a tsunami approaches the shore, wave run-up is the elevation above mean sea level on dry land that a tsunami reaches. A tsunami’s potential severity can be forecasted as a function of the wave’s mass along with the difference between the wave’s run-up height and the ground elevation of the affected coastal location.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at

great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

According to the 2018 San Diego County Hazard Mitigation Plan, the planning committee ranked the extent of tsunami as Moderate. The greatest type of tsunami risk is material damage to small watercraft, harbors, and some waterfront structures with flooding along the coast. (See the Estimate of Potential Losses section for additional data).

History of the Hazard:

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. That said, no tsunamis have impacted CSU campus locations.

According to the National Centers for Environmental Information (NCEI), have been eight tsunamis have caused damage to ports and harbors or coastal inundation in California since 1946. The most significant events are as follows:

- In 1964, a tsunami caused by a Magnitude 9.2 earthquake offshore from Alaska resulted in 13 deaths in California and destroyed portions of downtown Crescent City.
- A 2006 tsunami (originating in the Kuril Islands region north of Japan) caused approximately $20 million in damage to Crescent City harbor.
- A 2010 tsunami (originating offshore from Chile) caused millions of dollars in damage to ports and harbors in the state.
- A tsunami in 2011 (caused by a Magnitude 9.0 earthquake offshore of Japan) killed one person at the mouth of the Klamath River and caused up to $100 million of damage to 27 ports, harbors, and marinas throughout the State. The most damage occurred in Crescent City, Santa Cruz and Moss Landing harbors and a federal disaster was declared in Del Norte, Santa Cruz, and Monterey Counties. Both Crescent City and Santa Cruz harbors sustained damage to all docks, and oil spills and water/sediment contamination that resulted from sunk or damaged boats. Because recovery efforts in these two harbors took several years to complete, both harbors incurred business/economic losses that have been difficult to recapture.
- Historical Tsunami Run-Ups in San Diego County

The largest tsunami effect recorded in San Diego since 1950 was May 22, 1960, which had a maximum wave height 2.1 feet (NOAA, 1993). In this event, 80 meters of dock were destroyed and a barge sunk in Quivera Basin.
Other tsunamis felt in San Diego County: 75

- November 5, 1952, with a wave height of 2.3 feet and caused by an earthquake in Kamchatka;
- March 9, 1957, with a wave height of 1.5 feet;
- March 27, 1964 with a wave height of 3.7 feet,
- September 29, 2009 with a wave height of 0.5 feet,
- February 2010 with a wave height of 0.6 meters;
- June, 2011 with wave height of 2 feet.

Potential Impacts of the Hazard:

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing total devastation to coastal development.

The configuration of the coastline, the shape of the ocean floor, and the characteristics of advancing waves play important roles in the destructiveness of the waves. Bays, sounds, inlets, rivers, streams, offshore canyons, islands, and flood control channels may cause various effects that alter the level of damage. Offshore canyons can focus tsunami wave energy, and islands can filter the energy. It has been estimated that a tsunami wave entering a flood control channel could reach a mile or more inland, especially if it enters at high tide. The orientation of the coastline determines whether the waves strike head-on or are refracted from other parts of the coastline.

SDSU is not at risk to physical impacts from tsunamis. In carrying out its role as an evacuation center, the key potential impact is a depletion or exceedance of campus resources for managing a refugee population during emergency response.

Potential impacts to buildings and infrastructure within the county’s inundation zone include destruction of the natural environment, destruction of boats, as well as other coastal development, and loss of life. Tsunamis that impact both harbors and communities also can produce free-floating debris hazards and environmental contamination from chemical spills.

Probability of Future Occurrence of the Hazard:

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of

75 2018 San Diego County Hazard Mitigation Plan, p.33
California in the past 150 years. If we consider historical occurrence as one data set for estimating future events, the average rate of occurrence over the past 150 years is 1 tsunami every 1.9 years. Currently, no analysis is available which differentiates this statewide probability specifically for San Diego County, CA. Although 7 events have been recorded for the county between 1952 and 2021 (1 event every 9.8 years), it is prudent to utilize the 1.9-year statewide recurrence interval for planning purposes given extreme difficulties predicting tsunami points of origin.

The rate of future occurrence may change and may be able to make target estimates for specific locations in the future; the California State Tsunami Program is trying to refine the accuracy of the data. In doing so, the State Tsunami Program is completing a set of Probabilistic Tsunami Hazard Analysis (PTHA) maps representing risk levels from 100-year to 3000-year average return periods. Analysis using these probabilistically based products will allow for a more common platform for comparison to other seismic and flood probabilistic analyses.

Vulnerability to the Hazard:

With regard to CSU campus locations, direct vulnerability of assets and people to tsunami only applies to the CSU Chancellor’s Office in Long Beach, CA, as it is the only campus clearly located in a mapped tsunami zone.

With regard to SDSU, the campus planning committee indicates that no campus assets or people are vulnerable. However, campus staff and students may have reduced access to transportation routes during a tsunami evacuation.

Vulnerability of Populations

For SDSU, the campus population is not directly vulnerable to tsunami.

The populations most vulnerable to the tsunami hazard in San Diego County are the elderly, disabled and very young who reside near beaches, low-lying coastal areas, tidal flats and river deltas that empty into ocean going waters. In the event of a local tsunami generated near the San Diego coast, little warning time would exist, so more of the population would be vulnerable. According to the County’s 2018 Hazard Mitigation Plan, 10,360 residents live within the inundation zone.

Property Vulnerability

For San Diego County, the impact of tsunami waves and the scouring associated with debris that may be carried in the water could be damaging to all structures along beaches, low-lying coastal areas, tidal flats and river deltas. The most vulnerable structures are those in the front line of tsunami impact and those that are structurally unsound.

Critical Facilities and Infrastructure Vulnerabilities

No campus critical facilities or infrastructure are vulnerable to physical impacts from a tsunami wave. However, the following infrastructure is vulnerable to damage in San Diego County, CA:

- **Water Proximate Infrastructure**—Breakwaters and piers collapse, sometimes because of scouring actions that sweep away their foundation material and sometimes because of the sheer impact of the tsunami waves.
- **Flood Control Systems**—Floodwaters can back up drainage systems, causing localized flooding. Culverts can be blocked by debris from tsunami events, also causing localized urban flooding.
- **Utility Systems**—Floodwaters can get into drinking water supplies, causing contamination. Sewer systems can be backed up, causing waste to spill into homes, neighborhoods, rivers and streams. Tsunami waves can knock down power lines and radio/cellular communication towers. Power generation facilities can be severely impacted by wave action and by inundation from floodwater.
- **Fuels**—Destruction of fueling infrastructure and related environmental and potable water contamination can occur.

For more information on vulnerable building types and other property in San Diego County, please see the Estimate of Potential Losses section (below).

Estimate of Potential Losses:

Given that the campus is located outside of the inundation zone, an estimate of potential losses from a tsunami wave impact is not applicable.

For San Diego County, estimated dollar losses to vulnerable buildings and infrastructure lying within the inundation zone is provided (below):

**Summary of Potential Tsunami Exposure/Loss in San Diego:**

- Exposed Population (10,360)
- Number of Residential Buildings (5,357)
- Potential Loss Value of Residential Buildings ($1,507,996,000)
- Number of Commercial Buildings (1,736)
- Potential Loss Value of Commercial Buildings ($607,514,000)
- Number of Critical Facilities (37)
- Potential Loss Value of Critical Facilities ($51,550,000)

Vulnerability Assessment Conclusions:
According to the 2018 State of California Hazard Mitigation Plan, community exposure to tsunamis in California varies considerably—some communities may experience great losses that reflect only a small part of their community and others may experience relatively small losses that devastate them. Among the 94 incorporated communities and 83 unincorporated areas of the 20 coastal counties, the communities that are most vulnerable to injury and life safety issues exist within Del Norte and Humboldt counties while the cities of Alameda, Belvedere, Crescent City, Emeryville, Oakland, and Long Beach have the highest combinations of the number and percentage of people and businesses in tsunami-prone areas.

To improve tsunami vulnerability assessments, FEMA has developed a new tsunami loss estimation module for HAZUS using existing numerical model results for tsunami inundation, flow depth, velocity, and force. This HAZUS module allows new capability for estimation of economic losses, and site-specific analysis of content losses, casualties, infrastructure damage, and evacuation time. The module calibrates losses based on safe zones and community preparedness levels. Such technological improvements in assessment capability can be utilized for tsunami hazard analysis and planning purposes for SDSU.

Along with new probability-based tsunami maps, the HAZUS module will improve the ability to compare tsunami impacts to those of other hazards. Moreover, the probability mapping will be used for numerous applications including identifying potential tsunami hazard “zones of required investigation” under the Seismic Hazards Mapping Act and will assist state and local agencies in making land use planning decisions and will help regional and state planners understand the flood potential from tsunamis representing different risk levels. The improved analysis and data will be utilized by SDSU through its partnerships with key stakeholder organizations.77

Note: To download the Community Exposure to Tsunami Hazards in California report visit the USGS website: http://pubs.usgs.gov/sir/2012/5222/.

Identified Data Limitations:

As identified in the vulnerability conclusions (above), with regard to the current planning effort, the primary data limitations for assessing the tsunami hazard for CSU campuses mostly pertain to a complete set of valuations for the assets of the Chancellor’s Office campus lying within the tsunami inundation zone. In addition, the CSU system-wide effort would benefit from FEMA’s new probability mapping techniques and tsunami loss estimation module to the footprint of those campuses proximate to the inundation zone to ensure that the current “not at risk of direct impact” to staff, students and physical assets still holds true. That said, CSU leadership and planning teams intends to pursue such data in the future.

77 2018 State of California Hazard Mitigation Plan
**Volcano (Associated Air Quality)**

**Description of the Hazard**

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”  

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

**Location of the Hazard**

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of San Diego State University (SDSU) or San Diego County is within a volcano hazard zone.

**Extent of the Hazard**

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While SDSU does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as **Low**.

**History of the Hazard**

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic

________

---

eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As SDSU is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at SDSU.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For SDSU, there is low vulnerability to the immediate impacts of
volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

**Estimate of Potential Losses**

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

**Vulnerability Assessment Conclusions**

SDSU is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

**Identified Data Limitations**

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

---

**Wildfire**

**Description of the Hazard**

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression
actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another. The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

---

80 *State of California Hazard Mitigation Plan, September 2018*
A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

Location of the Hazard

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests, and other lands with high susceptibility to fire occurring throughout the state. San Diego State University (SDSU) is located on a set of bluffs overlooking Mission Valley, the San Diego River, and Alvarado Creek. Areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur to the west and north of the campus. Additionally, these fire hazard zones exist in other areas throughout San Diego County. These areas of higher fire hazards occurring near the campus are primarily located in the numerous creek channels leading to the San Diego River channel. Each of these hazard zones include light to moderate vegetation and are bordered by dense residential development.

The San Diego State University campus is located in the central portion of the City of San Diego. The area immediately to the south and east of the campus is predominately commercial and residential. The areas to the west and north include open hillsides and valleys combined with residential land uses. Fire Hazard Severity Zones are found on the western portions of the campus and throughout the hillsides surrounding the campus to include Very High Fire Hazard Severity Zones (VHFHSZ).

Figure 20-16: Fire Hazard Severity Zones near San Diego State University81

San Diego County has multiple areas considered as fire hazard zones that present direct threats of burning potential in areas that are in proximity to those hazard areas. Additionally, these large areas of land that are considered to be hazardous for the potential for fire will also produce the threat of diminished or hazardous air quality due to the smoke and particulates produced in the burning process. The air quality for residents of the County and the San Diego State University campus community can be greatly affected by large fires burning in these areas.

Fire Hazards Zones surrounding San Diego County demonstrate the broader community threat that wildfires present to the population. Fire hazard severity zones are found surrounding the populated areas of the county. This presents the potential for fire related damages and smoke inundation to occur in many areas that members of the campus community reside at, are employed in, or where they recreate. Transportation routes are equally impacted causing potential added challenges for the campus community to get to areas if safety, get resources, or gain access to the campus.
Extent of the Hazard

While the threat to fire directly affecting the campus is considerable, the direct effect of fire generated smoke is also likely to occur. Fires are likely to occur in close proximity to the campus generating smoke that could envelop the campus in the right atmospheric conditions. Fires that are large enough to generate volumes of smoke to cover great distances have the potential to affect the air quality of San Diego County, including the campus. This will especially be the case in weather conditions creating strong offshore winds. The potential for this impact has been demonstrated during the summers of 2018, 2019, and 2020 as fires burned across the state and spread smoke over vast distances. Fires burning well outside of the San Diego County region have the potential to distribute smoke onto the SDSU campus.

Given that the area immediately surrounding the SDSU campus is in proximity to fire hazard zones designated as High Fire Hazard Severity Zones (HFHSZ), and that the

---

County and surrounding hillsides are considered to be of high fire threat including Very High Fire Hazard Severity Zones (VHFHSZ), the planning committee ranks the extent of the wildfire hazard for the campus as High.

Moreover, as a large number of wildfires are ignited due to human caused factors, the ability to determine when or where a wildfire might occur is impossible. Only the conditions for a wildfire can be predicted with any accuracy.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 20-26: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L) COLOR CODE: Green</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M) COLOR CODE: Blue</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel – may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
</tbody>
</table>

### CLASS 3: High Danger (H)
**COLOR CODE:** Yellow

Fires start easily and spread at a rapid rate. All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.

### CLASS 4: Very High Danger (VH)
**COLOR CODE:** Orange

Fires start very easily and spread at a very fast rate. Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.

### CLASS 5: Extreme (E)
**COLOR CODE:** Red

Fire situation is explosive and can result in extensive property damage. Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
Figure 20-17: Air Quality Index for Ozone and Particulate Pollution

</tr>
</tbody>
</table>

History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. San Diego County also has a long history of wildfire activity primarily in the foothills and mountains. Wildfires occurring in the San Diego County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damages.

The area immediately surrounding the San Diego State University campus is in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within direct proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The San Diego campus has experienced days of poor air quality due to fires burning in parts of the county, although infrequent.

Potential Impacts of the Hazard

The location of the San Diego State University campus on a hillside near areas designated as High Fire Hazard Severity Zones places a threat that flame, ember, and smoke exposure from wildfire to the campus. There is potential for fire to occur from the west or north of the campus. The surrounding hillsides and valleys are composed of light to moderate fuels. Although the campus itself does not have a history of wildfire activity, the fire threat to campus structures from these neighboring hillsides and valleys is significant.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Threat or damage to on campus child care facilities
- Threatened structures on the north side of campus including Chapultepec Residence Hall, Huaxyacac Residence Hall, Metepec Residence Hall, Zapotec Residence Hall, Toltec Residence Hall, Mixquic Residence Hall, Zacatepec Residence Hall, Huaxtepec Residence Hall, Tarastec Residence Hall, International Student Center, Central Receiving, and the Villa Alvarado Residence Halls.
- Substantial on-campus student resident population reside within fire hazard zone requiring evacuation in fire events
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities, on campus power generation
- Damaged or destroyed critical facilities supporting campus emergency support needs

---

86 San Diego County Multi-Jurisdictional Hazard Mitigation Plan, October 2017
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:
- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts on pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of San Diego County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

**Probability of Future Occurrence of the Hazard**

Based on the wildfire threat potential in the area surrounding the San Diego State University campus and canyons along the north side of the campus, including the immediate proximity to Local Fire Hazard Severity Zones listed as “Very High”, the
density of residential and commercial development, and the historic occurrences of fires, the probability of wildfire related damage is considered Possible.

Based on the wildfire threat potential in the area surrounding Southern California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered Possible.

Vulnerability to the Hazard

The San Diego State University campus is subject to direct impact from wildfire due to the campus location within a wildland-urban interface zone. The campus is identified to reside near a designated local Very High Fire Hazard Severity Zone. The campus is adjacent to hillsides and open lands containing combustible vegetation combined with residential development. Additionally, vulnerabilities to the effects of wildfire would lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillsides to the north and west of campus and extending onto the campus or localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have significant impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures. Structures with vegetation and other combustibles near the structure increases the ability of fire to spread to buildings.

Additional concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill urban areas even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. San Diego State University students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity
will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the San Diego State University campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $726,584,983. However due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

| No Building Value Data Provided* | 68 | Unknown |

*Buildings with no value defined are also included in the respective Zones they are found in.
The table above includes 14 facilities located at the Calexico based San Diego State University, Imperial Valley campus. The provided cost estimates for the Imperial Valley campus includes $18,144,214. However, 12 facilities do not have costs included.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in San Diego County, including wildfire incidents that have threatened or caused secondary impacts to the San Diego State University campus. The location of the San Diego State University campus surrounded by densely developed residential, commercial, and industrial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities. The placement at the top of a bluff overlooking the San Diego River Valley exposes vulnerabilities to fire that may ignite along the hillside. The foothills and mountains surrounding San Diego County host environments that are ideal for the development of wildfire activity. The consequences of fires in these areas would present primary and secondary consequences to the San Diego State University campus and expose vulnerabilities on the campus and to the campus community.

The topography of the valleys surrounded by mountains allows for smoke filled air to linger in the valleys of the San Diego area with the potential for unhealthy air quality depending on wind conditions. Fires in the watersheds of the San Diego area mountains and tributaries may damage vegetation stabilizing hillsides and result in increased sediments to be discharged into the river system and reservoirs reducing their capacity and effectiveness. Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, Lightning)**

Description of the Hazard
Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases

---

89 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat

lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.91

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California.92 On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions.93 This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including San Diego State University.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.94

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including San Diego State), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate

91 Retrieved on 07.17.2021 from https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions
92 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
94 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.95

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.96 The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.97 These storms affect (in varying degrees) all CSU campuses, including San Diego State.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.98 Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.99 Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.100 **Severe thunderstorms** are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.101 102

---

95 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php

101 Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

102 Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.\(^{103}\)

- **Wind storm**: marked by high wind with little or no precipitation.\(^{104}\)

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\(^{105}\)

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.\(^{106}\)

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\(^{107}\)

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\(^{108}\)

### Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\(^{109}\) Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”\(^{110}\)

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including San Diego State).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\(^{111}\)

**Strong Winds**

---

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\textsuperscript{112}

\textbf{Thunderstorm Winds}

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\textsuperscript{113}

Please note: \textbf{Straight-line wind} is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\textsuperscript{114} However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

\textbf{Tornadoes}

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\textsuperscript{115} This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\textsuperscript{116} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{117}

\textbf{Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.}

\textbf{Santa Ana Winds.} A type of wind hazard that is peculiar to Southern California is called a \textit{Santa Ana Wind}. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{118} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located

\textsuperscript{112} Retrieved on 07.17.2021 from https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf

\textsuperscript{116} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/

\textsuperscript{117} Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions

off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\(^{119}\) (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

Figure 20-18: What Drives a Santa Ana Wind?\(^{120}\)

---

\(^{120}\) Retrieved on 07.14.2021 from https://twitter.com/nwslosangeles/status/933049473034579968
**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.121

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.122 123 124

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.125 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds;

the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.\textsuperscript{126}

\textbf{Lightning}

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\textsuperscript{127}

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{128} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

\textbf{Location of the Hazard}

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including either at the San Diego State University main campus or at satellite campus facilities owned by the school. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

\textbf{Extent of the Hazard}

Severe weather hazards are non-spatial hazards that potentially affect all San Diego State campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to San Diego State campuses reflect those of the surrounding community and County. As a result, all assets and people at San Diego State campuses are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the San Diego (San Diego County), Brawley (Imperial County), and Calexico (Imperial County)

areas, as well as the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.\(^{129}\) First developed in 1805, it is still used today to estimate wind strengths.\(^{130}\)

Very rarely experienced; accompanied by widespread damage.

| 12 | 73+ | 64+ | Hurricane | The air is filled with foam and spray. Sea completely white with driving spray; visibility very seriously affected.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as MODERATE.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{132}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

**Table 20-30: Fujita Tornado Scale (Pre-February 2007)**\(^{133}\)

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the hail hazard as **LOW**.

**Extent: Lightning**

The National Weather Service (NWS) uses a Lightning Activity Level (LAL) scale to indicate the frequency and character of cloud-to-ground (C/G) lightning. The scale uses a range of 1 – 6, with 6 being the high end of the scale. Table below provides details of the LAL scale.
<table>
<thead>
<tr>
<th>Rank</th>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no established, objective severity scale for thunderstorms.\(^{137}\)\(^{138}\) That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as **light, medium, or heavy** according to following five (5) characteristics:

- the nature of the lightning and thunder;

\(^{137}\) Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

\(^{138}\) Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
the type and intensity of the precipitation, if any;

• the speed and gustiness of the wind;

• the appearance of the clouds; and

• the effect upon surface temperature.\(^{139}\)

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

• **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;\(^{140}\)

• **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\(^{141}\) or

• **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\(^{142}\)\(^{143}\)

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

**History of the Hazard**

Severe weather hazards have been an annual occurrence in San Diego County and on the San Diego State main campus. Severe weather hazards have also been an annual occurrence in Imperial County and on the San Diego State – Imperial Valley campuses in Brawley, CA and Calexico, CA. Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type. For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events. To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**San Diego County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in San Diego County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind**: at least 434 events, or approximately 17.13 events per year
- **Strong Wind**: at least 61 events, or 2.41 events per year

Retrieved 07.30.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=SAN%2BDIEGO%3A73&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitButton=Search&statefips=6%2CCALIFORNIA
149 National Climatic Data Center. Storm Events Database. Retrieved 07.30.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+Strong+Wind&beginDate_mm=
- **Thunderstorm Wind**: at least 88 events, or approximately 3.47 events per year\(^{150}\)

- **All Wind Hazard events** (excluding Tornadoes): at least 577 events, or approximately 22.78 events per year.\(^{151}\)\(^{152}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in San Diego County, there have been at least 577 wind hazard events since 1996, excluding tornadoes.\(^{153}\)\(^{154}\) That translates to an approximate average historical frequency of occurrence of **22.78** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 583 events) and simultaneous Database searches of all severe weather hazard events (i.e., 577 events) may be due to the following factors: (1)
multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado,” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for San Diego County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County. When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 577 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for San Diego County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that San Diego County has experienced since 1996 have been costly. There have been 7 deaths and 29 injuries, and property and crop damage estimates have totaled approximately $44,415,000 and $36,745,000, respectively.

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 13 reported events of tornadoes in San Diego County, which translates to approximately 0.51 tornado events per year.

The vast majority of tornado reports in San Diego County since 1996 have been of tornadoes with a severity rating of F0/EF0. Only two (2) of the tornadoes reported have...
been rated F1/EF1 or higher; both have been F1/EF1 tornadoes.\textsuperscript{159} That means that approximately 0.08 F1/EF1 tornado hazard events have occurred per year in San Diego County.

**Historical Tornado Hazard Losses for San Diego County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that San Diego County has experienced since 1996 have been costly. While there have been no reported deaths, injuries, or crop damage, property damage estimates have totaled approximately $219,600.\textsuperscript{160}

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 39 reported events of hail in San Diego County, which translates to approximately 1.54 hail events per year.\textsuperscript{161}

**Historical Hail Hazard Losses for San Diego County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that San Diego County has experienced since 1996 have been costly. While there have been no deaths, there have been five (5) injuries, and property and crop damage estimates have totaled approximately $40,000 and $310,000, respectively.\textsuperscript{162}

**Lightning**

miles away, but are erroneously recorded as events that have occurred in the County.¹⁶⁷ When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 662 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for San Diego County since 1996**

According to the NCEI Storm Events Database, the severe weather events that San Diego County has experienced since 1996 have been costly. There have been 8 deaths and 41 injuries, and property and crop damage estimates have totaled approximately $32,874,000 and $36,955,000, respectively.¹⁶⁸ ¹⁶⁹ However, it is important to note that for all San Diego County severe weather hazard events recorded on the Storm Events Database, almost all (i.e., 87.5%) deaths, the majority (i.e., 70.7%) of all injuries, and almost all (i.e., 99.2%) reported property and crop damage estimates have been attributed to wind hazard events alone.

**Imperial County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Imperial County since 1996.¹⁷⁰ Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.¹⁷¹

miles away, but are erroneously recorded as events that have occurred in the County. When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 59 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Imperial County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Imperial County has experienced since 1996 have been costly. While there have been no deaths or crop damages reported, there has been one (1) injury, and property damage estimates have totaled approximately $5,891,000.178

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been two (2) reported events of tornadoes in Imperial County, which translates to approximately 0.08 tornado events per year; both tornadoes have been rated F0/EF0.179

**Historical Tornado Hazard Losses for Imperial County since 1996**

According to the NCEI Storm Events Database, there have been no tornado-related deaths, injuries, property damage, or crop damage.180

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been eight (8) reported events of hail in Imperial County, which translates to...
approximately 0.32 hail events per year.\textsuperscript{181} (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of nine (9) reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County coastal areas that are not proximal to Imperial County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Imperial County since 1996**

There have been no hail-related deaths, injuries, property damage, or crop damage in Imperial County since 1996.\textsuperscript{182} (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Imperial County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there has been one (1) reported event of lightning in Imperial County, which translates to approximately 0.04 lightning events per year.\textsuperscript{183}

**Historical Lightning Hazard Losses for Imperial County since 1996**

There have been no lightning-related deaths, injuries, property damage, or crop damage in Imperial County since 1996.\textsuperscript{184}

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

(Imperial County)

Information obtained from the NCEI Storm Events Database indicates that there have been 70 occurrences of the severe weather hazard in Imperial County. This translates to 2.76 severe weather hazard occurrences per year.\textsuperscript{185}

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 76 events) and simultaneous Database searches of all severe weather hazard events (i.e., 70 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Imperial County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{186} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 70 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Imperial County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Imperial County has experienced since 1996 have been costly. While there have been no deaths or crop damage, there has been one (1) injury, and property damage estimates have totaled approximately $5,891,000.\textsuperscript{187} It is important to note that for all Imperial County severe weather hazard events recorded on the Storm Events Database, all injuries and all estimated property damage have been attributed to wind hazard events alone.

**Wind Hazards Not Included in the NCEI Storm Events Database**

*Santa Ana Winds*

\textsuperscript{185} Re National Climatic Data Center. Storm Events Database. Santa Ana wind events occur at least twice per month from October through April.\textsuperscript{188} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textbf{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6 days accounting for 90\% of all occurrences. The remaining 10\% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{189, 190}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

**Diablo Winds**

Diablo wind events occur approximately *2.5 events per year*. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^{193}\)

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\(^\text{194}\)

Figure 20-20: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\(^\text{195}\)

\[\text{Sundowner Winds}\]

Strong sundowner wind events occur approximately \textbf{2-3 times per year}. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\(^\text{196}\)

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within San Diego State main campus and satellite campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the San Diego State campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.
Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

**San Diego State Main Campus, San Diego (San Diego County)**

The 2017 San Diego County Multi-Jurisdictional Hazard Mitigation Plan profiles only one severe weather-related hazard – coastal storm/coastal erosion/tsunami hazard. High winds are a component of this hazard. Damage from high wind speeds by themselves is considered to be minor, although they contribute to storm surge and erosion. As a result, wind hazards (including tornadoes) are considered to be of low to moderate significance, and therefore to have a minimal to moderate potential impact on the County and on the San Diego State main campus. Tornadoes are not profiled at all by the Plan. As a result, tornado hazards are considered to be of low significance, and therefore to have minimal potential impact on the County and on the San Diego State main campus.197

**San Diego State – Imperial Valley Campuses, Brawley and Calexico (Imperial County)**

According to the 2021 Imperial County Multi-Jurisdictional Hazard Mitigation Plan (MHMP), “Extreme Weather” sub-hazards like windstorms and tornadoes are considered to be significant for Imperial County, and therefore to have a moderate to high potential impact on the County and on the San Diego State – Imperial Valley campuses.198

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

**San Diego State Main Campus, San Diego (San Diego County)**

The 2017 San Diego County Multi-Jurisdictional Hazard Mitigation Plan profiles only one severe weather-related hazard – coastal storm/coastal erosion/tsunami hazard. Hail hazards are not profiled in the Plan. As a result, hail hazards are considered to be of low significance, and therefore to have a minimal potential impact on the County and on the San Diego State main campus.199

**References**

San Diego State – Imperial Valley Campuses, Brawley and Calexico (Imperial County)

According to the 2021 Imperial County Multi-Jurisdictional Hazard Mitigation Plan (MHMP), an “Extreme Weather” sub-hazard like hail is considered to be significant for Imperial County, and therefore to have a moderate to high potential impact on the County and on the San Diego State – Imperial Valley campuses.200

Lightning

Lightning strikes the United States about 20-25 million times a year.201 Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.202 Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.203 (Commercial claim payouts for lightning losses for the U.S. were not available.)

San Diego State Main Campus, San Diego (San Diego County)

The 2017 San Diego County Multi-Jurisdictional Hazard Mitigation Plan profiles only one severe weather-related hazard – coastal storm/coastal erosion/tsunami hazard. Lightning hazards are not profiled in the Plan. As a result, lightning hazards are considered to be of low significance, and therefore to have a minimal potential impact on the County and on the San Diego State main campus.204

San Diego State – Imperial Valley Campuses, Brawley and Calexico (Imperial County)

According to the 2021 Imperial County Multi-Jurisdictional Hazard Mitigation Plan (MHMP), an “Extreme Weather” a sub-hazard like a thunderstorm is considered to be significant for Imperial County, and therefore to have a moderate to high potential impact on the County. By definition, lightning is a hazard that is always present in a thunderstorm. As a result, lightning is also considered to have a “medium” or moderate

to high potential impact on the County and (by extension) on the San Diego State – Imperial Valley campuses.205

Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year. Future occurrences of such events are projected to increase in both their frequency and intensity.

**San Diego State Main Campus, San Diego (San Diego County)**

The 2017 San Diego County Multi-Jurisdictional Hazard Mitigation Plan states that damage from high wind speeds by themselves is considered to be minor, although they do contribute to storm surge and erosion.206 However, according to the NCEI Storm Events Database, wind, hail, and lightning events occur on average far more than once per year, with wind hazard events occurring on average 22.78 per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the San Diego State main campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the San Diego State main campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2017 San Diego County Multi-Jurisdictional Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the San Diego State main campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for San Diego State is **HIGHLY LIKELY**.

**San Diego State – Imperial Valley Campuses, Brawley and Calexico (Imperial County)**

The 2021 Imperial County Multi-Jurisdictional Hazard Mitigation Plan (MHMP) states that there is an 80% chance (i.e., “high” probability) that each of the severe weather hazards profiled above (i.e., wind, tornado, hail and lightning) will occur in the future.207 Also, according to the NCEI Storm Events Database, wind hazard events have occurred in Imperial County significantly more than once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the San Diego State...
University – Imperial Valley campuses equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the San Diego State – Imperial Valley campuses reflect those of the surrounding community and County.

Based on the data available from both the 2021 Imperial County Multi-Jurisdictional Hazard Mitigation Plan (MHMP) and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the San Diego State – Imperial Valley campuses at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for San Diego State – Imperial Valley is **HIGHLY LIKELY**.

**San Diego State University – All Campus Areas**

The probability of future occurrence of the severe weather hazard for all San Diego State University campus areas is **HIGHLY LIKELY**.

The following tables show the probabilities of future occurrence for component severe weather hazards for San Diego State campuses in San Diego County and Imperial County.

**Table 20-36: Severe Weather Hazard Probabilities of Future Occurrence for San Diego County and San Diego State University.**

Vulnerability to the Hazard

People, structures, and assets on all San Diego State campuses are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. San Diego State also has vehicles that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the all San Diego State campuses. Each of the hazards associated with severe weather can result in losses throughout the planning areas.
All structures at all San Diego State campuses are at risk from severe weather. There are approximately 215 buildings that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $726,584,983 for 147 buildings, and unknown for the remaining 68 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at the San Diego State campus varies throughout the day. As of Fall, 2019, San Diego State had 35,081 students and 3,702 faculty and staff. All are at risk from severe weather events, with 38,783 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to all San Diego State campuses. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to San Diego State.

It is evident that San Diego State has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated

208 Retrieved on 07.19.2021 from https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
20.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.
