Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU East Bay, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an
eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

**Estimate of Potential Losses**

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

**Vulnerability Assessment Conclusions**

CSU East Bay is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

**Identified Data Limitations**

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.
Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

Topography – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

Weather – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

Fuels – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

Location of the Hazard

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. The campuses in Hayward and Concord are located in the hills of the San Francisco East Bay. These hills are largely covered in moderate to high fuel density areas. In general, areas considered to be within Local Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur immediately south of the Hayward campus and south of the Concord campus. These hills surrounding the East Bay communities can be topographically diverse, contain heavier vegetative fuels, and often have residential development interspersed.

The CSU East Bay /Hayward campus is located in the hills of the eastern portion of the City of Hayward. The area immediately surrounding the campus is predominately developed with residential land uses. The campus has open fields containing short grasses and moderate fuels to the south of the main campus. The area to the south of campus is designated as a Local High Fire Hazard Severity Zone. To the north of the campus, are residential neighborhoods. To the north of the campus, are residential neighborhoods and a valley containing Ward Creek containing heavy fuels.

The CSU Easy Bay /Concord campus is located in the hills of Concord near the base of Mt. Diablo. The campus has open fields containing short grasses and moderate fuels to the south and west of the campus. The area to the south of campus is designated as a Local High Fire Hazard Severity Zone. To the north of campus are residential neighborhoods across Ygnacio Valley Road, however grassy fields lie between the campus and the road. To the east of the campus are residential neighborhoods separated by open grassy fields.
Figure 8-12: Hayward County Fire Hazard Severity Zones

Figure 8-13: Contra Costa County Fire Hazard Severity Zones

Extent of the Hazard

While the threat to fire directly affecting the campus is considerable, the direct effect of fire generated smoke is also likely to occur. Fires are likely to occur in close proximity to the campus generating smoke that could envelop the campus in the right atmospheric conditions. Fires that are large enough to generate volumes of smoke to cover great distances have the potential to affect the air quality of the San Francisco Bay Area including the campus. This will especially be the case in weather conditions creating strong offshore winds. The potential for this impact has been demonstrated during the summers of 2018, 2019, and 2020 as fires burned across the state and spread smoke over vast distances. Fires burning well outside of the Alameda County region have the potential to distribute smoke onto the CSU East Bay campus.

Given that the area immediately surrounding the CSU East Bay campus is in proximity to fire hazard zones designated as High Fire Hazard Severity Zones (HFHSZ), and that the County and surrounding hillsides are considered to be of high fire threat including Very
High Fire Hazard Severity Zones (VHFHSZ) with a history of wildfires, the planning committee ranks the extent of the wildfire hazard for the campus as High.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 8-27: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### CLASS 4: Very High Danger (VH)

**COLOR CODE:** Orange

- Fires start very easily and spread at a very fast rate.
- Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.

### CLASS 5: Extreme (E)

**COLOR CODE:** Red

- Fire situation is explosive and can result in extensive property damage.
- Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
Table 8-28: Air Quality Index for Ozone and Particulate Pollution

<tr>
<td>Maroon</td>
<td>Hazardous</td>
<td>301 and higher</td>
<td>Health warning of emergency conditions: everyone is more likely to be affected.</td>
</tr>
</tbody>
</table>

History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. California Department of Forestry and Fire Protection also has a long history of wildfire activity primarily in the foothills and mountains of the Oakland Hills, Hayward Hills, and Diablo Range. Wildfires occurring in Alameda County have resulted in thousands of acres burned and millions of dollars in damages.

80 California Department of Forestry and Fire Protection. Stats and Events. Retrieved 05.03.2021 from: https://www.fire.ca.gov/stats-events/
The area immediately surrounding the CSU East Bay campus is in proximity to fire hazard zones designated as High Fire Hazard Severity Zones (HFHSZ). Additionally, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The East Bay campus has experienced multiple days of poor air quality due to fires burning in Bay Area and neighboring counties. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including the San Francisco Bay Area. CSU East Bay personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

*Includes acreage across six counties (Alameda, Contra Costa, Merced, San Joaquin, Santa Clara, and Stanislaus)

Fire has contributed significantly to Alameda County’s hazard and disaster history. Some particular fires that have shaped the way fire plays into preparedness, planning, response, recovery, and mitigation efforts are described in the following.

The October 1991 Tunnel Fire, otherwise known as the Oakland Hills Fire, occurred in the hills of eastern Oakland, CA. Strong winds, drought, low humidity, heavy fuels, and inadequate separations between fuels and structures allowed an earlier fire to rekindle and rapidly spread. This fire clearly demonstrated the challenges faced in a wildland urban interface environment. The area affected is a residential community of Oakland comprising thousands of homes. The fire required a massive mutual aid effort forced the evacuation of several neighborhoods, burned 3,354 structures, killed 25 people, and resulted in $1.5 billion in damages.  

Potential Impacts of the Hazard

The location of the CSU East Bay campus on a hillside near areas designated as High Fire Hazard Severity Zones places a threat that flame, ember, and smoke exposure from wildfire to the campus. There is potential for fire to occur from any direction of the campus. The surrounding hillsides and valleys are composed of light to moderate fuels. The threat from fire and the impacts fire would have on the university is due to the campus being located adjacent to open hillsides and field susceptible to fire spread.

Potential impacts to the campus community resulting from wildfires include:

Injuries or loss of life

Campus property destruction or damage

Residential property destruction or damage

Commercial property destruction or damage

Loss of property contents

Infrastructure damage

Damaged or destroyed lifelines/supply routes

Damaged or destroyed utilities

Damaged or destroyed critical facilities supporting campus emergency support needs

Threat or damage to power plant

Loss of community economic base

Employment losses

Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events

Agricultural (crops and livestock) damages or destruction

Environmental damage

Societal and community impacts

Damage to organizations and facilities providing support services to vulnerable populations

Greater evacuation challenges for those most vulnerable

Psychological impacts of impacted populations

Disruptions to education delivery to community

-------------

8-98
Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Alameda County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the wildfire threat potential in the area on and surrounding the CSU East Bay campus and the CSU East Bay Concord campus, including the immediate proximity to hillsides with extensive vegetative growth, and the historic occurrences of fires, the probability of wildfire related damage and impacts from smoke is considered Possible.

Based on the wildfire threat potential in the area surrounding the campus and the San Francisco East Bay region, including the volume of areas in elevated Fire Hazard Severity Zones throughout the Alameda and Contra Costa Counties, the past occurrences of wildfire generated smoke from areas beyond Alameda County, the probability of wildfire generated smoke impacts to air quality is considered Possible.

Vulnerability to the Hazard

The CSU East Bay campus is subject to direct impact from wildfire due to the campus location within a wildland-urban interface zone. The campus is identified to reside near a designated local High Fire Hazard Severity Zone. The campus is surrounded on three sides by hillsides and open lands containing combustible vegetation combined with residential development. Additionally, vulnerabilities to the effects of wildfire would lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of
people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillsides and extending onto the campus or localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have significant impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures. Structures with vegetation and other combustibles near the structure increases the ability of fire to spread to buildings.

Access to the west using Carlos Bee Blvd or Harder Road servicing access to Hayward could become cutoff during fire incidents. Hayward Blvd exiting the back of campus may also be impacted by fire making it impassible. The university is limited by these routes for access to and from the campus. Access for supplies, equipment, and emergency services in addition to evacuation away from the campus would likely be forced to use alternative routes into Hayward.

Additional concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Bay Area even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU East Bay students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU East Bay campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.
Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $164,768,550. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

**Vulnerability Assessment Conclusions**

The occurrence of wildfires has been a frequent event in Alameda County, including wildfire incidents that have threatened the CSU East Bay campus and the Concord campus. The location of the CSU East Bay campus exposed to open hillsides with light to moderate vegetative fuels along the western edges presents a threat of fire to the campus community and campus assets. The Concord campus is similarly exposed to the open fields and hillside from the base of Mt. Diablo. These environments are ideal for the development of wildfire activity in the right conditions. The consequences of fires in these areas would present primary and secondary consequences to the CSU East Bay campuses and expose vulnerabilities on the campus and to the campus community.
The topography and weather conditions of the region allows for smoke filled air to linger in the valleys of San Francisco Bay Area with the potential for unhealthy air quality depending on wind conditions. Large fires burning from even far away locations in northern California have demonstrated to fill expansive areas with smoke filled air.

Communities located within or near the Wildland Urban Interface throughout the Bay Area may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, and homeless students.

**Identified Data Limitations**

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Lightning, Hail)**

*Description of the Hazard*

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

---

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU East Bay.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected

---

85 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat
88 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU East Bay), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.

**Types of Storms in California**

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage. The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California. These storms affect (in varying degrees) all CSU campuses, including CSU East Bay.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere. Thunderstorms can produce some of nature’s most destructive and
deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{96} \textit{Severe thunderstorms} are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\textsuperscript{97} \textsuperscript{98}

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.\textsuperscript{99}
- **Wind storm**: marked by high wind with little or no precipitation.\textsuperscript{100}
- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\textsuperscript{101}
- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.\textsuperscript{102}
- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\textsuperscript{103}
- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially

\textsuperscript{96} Retrieved on 07.14.2021 from https://www.noaa.gov/explainers/severe-storms

\textsuperscript{98} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\textsuperscript{104}

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: \textbf{wind hazards (including tornadoes), hail, and lightning}. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

\textbf{Wind} is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\textsuperscript{105} Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” \textsuperscript{106}

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU East Bay).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\textsuperscript{107}

\textsuperscript{106} Retrieved on 07.15.2021 from https://forecast.weather.gov/glossary.php?word=wind%20gust

\textsuperscript{107} Retrieved on 07.17.2021 from https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf
**Strong Winds**

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\(^{108}\)

**Thunderstorm Winds**

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\(^{109}\)

Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\(^{110}\) However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

**Tornadoes**

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\(^{111}\) This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\(^{112}\) On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\(^{113}\)

**Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.**

**Santa Ana Winds.** A type of wind hazard that is peculiar to Southern California is called a **Santa Ana Wind.** Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\(^{114}\) They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal

\(^{111}\) Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/

\(^{112}\) Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/

\(^{113}\) Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions

component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\(^{115}\) (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

Figure 8-14: What Drives a Santa Ana Wind?\(^{116}\)

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are

---

offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.\textsuperscript{117}

\textbf{Sundowner Winds.} Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.\textsuperscript{118 119 120}

\textit{Hail}

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.\textsuperscript{121} It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the

\begin{itemize}
\item \textsuperscript{117} Retrieved on 07.13.2021 from https://www.fireweather.org/diablo-winds
\item \textsuperscript{121} Retrieved on 07.14.2021 from https://www.nssl.noaa.gov/education/svrwx101/hail/
\end{itemize}
strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.\textsuperscript{122}

\textbf{Lightning}

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000\textdegree F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\textsuperscript{123}

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{124} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

\textbf{Location of the Hazard}

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including either at the CSU East Bay main campus or at satellite campus facilities owned by the school. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

\textbf{Extent of the Hazard}

Severe weather hazards are non-spatial hazards that potentially affect all CSU East Bay campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU East Bay campuses reflect those of the surrounding community and County. As a result, all assets and people at CSU East Bay campuses are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Hayward (Alameda County), Oakland (Alameda County), and Concord (Contra Costa County), and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the

Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{128}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 8-32: Fujita Tornado Scale (Pre-February 2007)\(^{129}\)

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no...
established, objective severity scale for thunderstorms.133 134 That said, according to the Glossary of Meteorology published by the American Meteorological Society (AMS), a thunderstorm is reported as light, medium, or heavy according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.135

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;136

- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;137 or

- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder). 138 139

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.
History of the Hazard

Severe weather hazards have been an annual occurrence in Alameda County and Contra Costa County, as well as on CSU East Bay main campus (Alameda County) and satellite campus (Contra Costa County). Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA's National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type. For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events. To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**Alameda County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Alameda County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind**: at least 88 events, or approximately 3.47 events per year

---

144 National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=ALAMEDA%3A1&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA
- **Strong Wind**: at least 253 events, or 9.97 events per year\textsuperscript{145}
- **Thunderstorm Wind**: at least 8 events, or approximately 0.32 events per year\textsuperscript{146}
- **All Wind Hazard events** (excluding Tornadoes): at least 343 events, or approximately 13.54 events per year.\textsuperscript{147} (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Alameda County, there have been at least 343 wind hazard events since 1996, excluding tornadoes.\textsuperscript{148} That translates to an approximate average historical frequency of occurrence of **13.54** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 349 events) and simultaneous Database searches of all severe weather hazard events (i.e., 343 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Alameda County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{149}

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 343 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical Wind Hazard Losses for Alameda County since 1996

According to the NCEI Storm Events Database, the wind hazard events that Alameda County has experienced since 1996 have been costly. There have been 5 deaths and 9 injuries, and property damage estimates have totaled approximately $6,974,000; there have been no crop damages reported.\(^\text{150}\)

Tornado Wind Hazards

Information from the NCEI Storm Events Database indicates that since 1996, there have been no reported tornadoes hazard events in Alameda County.\(^\text{151}\)

Historical Tornado Hazard Losses for Alameda County since 1996

Because there have been no reported tornado hazard events for Alameda County since 1996, there are no tornado hazard event losses for that time period.

Hail

Information from the NCEI Storm Events Database indicates that since 1996, there have been 19 reported events of hail in Alameda County, which translates to approximately 0.75 hail events per year.\(^\text{152}\) (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 20 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Alameda County. The origin of this discrepancy is unknown at this time.)

Historical Hail Hazard Losses for Alameda County since 1996

According to the NCEI Storm Events Database, the hail hazard events that Alameda County has experienced since 1996 have been costly. While there have been no deaths or injuries, property damage estimates have totaled approximately $5,000,000; additional but negligible property damage (i.e., $10) and crop damage estimates (i.e., $10) have also

or “Hail” that are reported for Alameda County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.  

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 364 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Alameda County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Alameda County has experienced since 1996 have been costly. There have been 5 deaths and 9 injuries, and property and crop damage estimates have totaled approximately $11,977,000 and $10, respectively.  

*It is important to note that for all Alameda County severe weather hazard events recorded on the Storm Events Database, all deaths and injuries, as well as 58.2% of all property damage estimates, have been attributed to wind hazard events alone. Almost all of the remaining property damage estimates (i.e., 41.7%) have been attributed due to hail hazard events. Reported crop damage estimates have been negligible.*

**Contra Costa County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database shows the number of events (or occurrences) of wind hazard events in Contra Costa County since 1996.  

Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind:** at least 88 events, or approximately 3.47 events per year

---

- **Strong Wind**: at least 253 events, or 10.0 events per year\(^{162}\)
- **Thunderstorm Wind**: at least 7 events, or approximately 0.28 events per year\(^{163}\)
- **All Wind Hazard events** (excluding Tornadoes): at least 342 events, or approximately 13.50 events per year.\(^{164}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Contra Costa County, there have been at least 342 wind hazard events since 1996, excluding tornadoes.\(^{165}\) That translates to an approximate average historical frequency of occurrence of 13.50 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 348 events) and simultaneous Database searches of all severe weather hazard events (i.e., 342 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as "Thunderstorm Wind" or "Hail" that are reported for Contra Costa County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{166}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 342 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Information obtained from the NCEI Storm Events Database indicates that there have been 357 occurrences of the severe weather hazard in Contra Costa County. This translates to 14.09 severe weather hazard occurrences per year.175

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 364 events) and simultaneous Database searches of all severe weather hazard events (i.e., 357 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado,” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Contra Costa County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.176 When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 357 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical, Aggregated Severe Hazard Losses for Contra Costa County since 1996

According to the NCEI Storm Events Database, the severe weather events that Contra Costa County has experienced since 1996 have been costly. There have been five (5) deaths and nine (9) injuries, and property damage estimates have totaled approximately $7,239,000; no crop damages have been reported.177 It is important to note that for all Contra Costa County severe weather hazard events recorded on the Storm Events Database, all deaths and injuries, and 96.2% of all property damage estimates have been attributed to wind hazard events alone.

Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April.178 From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa

Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.¹⁷⁹ ¹⁸⁰

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Figure 8-15: Mean Annual Frequency of Santa Ana Wind events (1948-2012)¹⁸¹ ¹⁸²

**Diablo Winds**

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^{183}\)

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\(^{184}\)

---

\(^{184}\) Retrieved on 07.15.2021 from https://www.fireweather.org/diablo-winds
Sundowner Winds

Strong sundowner wind events occur approximately **2-3 times per year**. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\(^{185}\)

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within all CSU East Bay campus areas are at risk from the effects of severe weather hazards.

Wind Hazards (Including Tornadoes)

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at CSU East Bay campuses, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.
Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

**CSU East Bay Main Campus, Hayward, and Oakland Center, Oakland (Alameda County)**

The City of Hayward Local Hazard Mitigation Plan 2015 does not identify any wind hazards (including tornadoes) as significant; however, the City of Oakland’s 2021-2026 Hazard Mitigation Plan identifies “high wind” as a significant severe weather hazard that has a “high” impact on people and a “low” impact on property in the community.\(^{187} \) \(^{188} \)

As a result, wind hazards are considered to have a moderate potential impact on both communities and (by extension) on both the CSU East Bay main campus and the CSU East Bay – Oakland Center campus.

**CSU East Bay – Concord Campus, Concord (Contra Costa County)**

The 2018 Contra Costa County Hazard Mitigation Plan groups together several sub-hazards (i.e., heavy rains/atmospheric rivers/thunderstorms, extreme heat, and damaging winds) into one all-encompassing “severe weather” hazard; in the Plan, the severe weather hazard is considered to have a “medium” impact on people and a “low” impact on property in the community. As a result, wind hazards (including tornadoes) are considered to have a minimal to moderate potential impact on the CSU East Bay – Concord campus.\(^{189} \)

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

**CSU East Bay Main Campus, Hayward, and Oakland Center, Oakland (Alameda County)**

Neither of the Alameda County communities in which CSU East Bay campuses are located (i.e., Hayward and Oakland) identifies hail as a significant hazard; therefore, hail is

not profiled as a hazard in either community’s local hazard mitigation plan. Because of this, hail hazards are considered to have a minimal potential impact on both communities and (by extension) on both the CSU East Bay main campus and the CSU East Bay – Oakland Center campus.

**CSU East Bay – Concord Campus, Concord (Contra Costa County)**

The 2018 Contra Costa County Hazard Mitigation Plan groups together several sub-hazards (i.e., heavy rains/atmospheric rivers/thunderstorms, extreme heat, and damaging winds) into one all-encompassing “severe weather” hazard; in the Plan, the severe weather hazard is considered to have a “medium” impact on people and a “low” impact on property in the community. As a result, hail hazards are considered to have a minimal to moderate potential impact on the CSU East Bay – Concord campus.

**Lightning**

Lightning strikes the United States about 20-25 million times a year. Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured. Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year. (Commercial claim payouts for lightning losses for the U.S. were not available.)

**CSU East Bay Main Campus, Hayward, and Oakland Center, Oakland (Alameda County)**

Neither of the Alameda County communities in which CSU East Bay campuses are located (i.e., Hayward and Oakland) identifies lightning as a significant hazard; therefore, lightning is not profiled as a hazard in either community’s local hazard mitigation plan.

---

Because of this, lightning hazards are considered to have a minimal potential impact on both communities and (by extension) on both the CSU East Bay main campus and the CSU East Bay – Oakland Center campus.

**CSU East Bay – Concord Campus, Concord (Contra Costa County)**

The 2018 Contra Costa County Hazard Mitigation Plan groups together several sub-hazards (i.e., heavy rains/atmospheric rivers/thunderstorms, extreme heat, and damaging winds) into one all-encompassing “severe weather” hazard; in the Plan, the severe weather hazard is considered to have a “medium” impact on people and a “low” impact on property in the community. As a result, lightning hazards are considered to have a minimal to moderate potential impact on the CSU East Bay – Concord campus.198

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year. Future occurrences of such events are projected to increase in both their frequency and intensity.

**CSU East Bay Main Campus, Hayward, and Oakland Center, Oakland (Alameda County)**

The City of Hayward Local Hazard Mitigation Plan 2015 does not identify any wind hazards (including tornadoes) as significant; however, the City of Oakland’s 2021-2026 Hazard Mitigation Plan identifies “high wind” as a significant hazard that has a “high” probability of occurrence (i.e., likelihood of annual occurrence).199 200 Also, according to the NCEI Storm Events Database, wind hazards have occurred in both communities and across the County far more than once annually – at an average of 13.54 wind hazard events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of both CSU East Bay campus locations in Alameda County equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather

probabilities for both the CSU East Bay main campus and the CSU East Bay – Oakland Center campus reflect those of the surrounding communities and County.

Based on the data available from the aforementioned local hazard mitigation plans and from the NCEI Storm Events Database, the severe weather hazard (in the form of wind hazards) is expected to occur on (or otherwise impact) both CSU East Bay campuses located in Alameda County campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for both the CSU East Bay main campus and the CSU East Bay – Oakland Center campus is **HIGHLY LIKELY**.

**CSU East Bay – Concord Campus, Concord (Contra Costa County)**

The 2018 Contra Costa County Hazard Mitigation Plan identifies severe weather (including damaging winds and thunderstorms) as a significant hazard that has a “high” probability of occurrence, and states that the County planning area can expect to experience exposure to and adverse impacts from some type of severe weather event at least annually. Also, according to the NCEI Storm Events Database, some of these same severe weather hazards have occurred in Contra Costa County at least once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU East Bay – Concord campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU East Bay – Concord campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2018 Contra Costa County Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU East Bay – Concord campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for the CSU East Bay – Concord campus is **HIGHLY LIKELY**.

**CSU East Bay – All Campus Areas**

The probability of future occurrence of the severe weather hazard for all CSU East Bay campus areas is **HIGHLY LIKELY**.

The following tables show the probabilities of future occurrence for component severe weather hazards for CSU East Bay campuses in Alameda County and Contra Costa County.

---

Table 8-38: Severe Weather Hazard Probabilities of Future Occurrence for Alameda County and CSU East Bay (Main Campus and Oakland Conference Center)

Vulnerability to the Hazard

People, structures, and assets on all CSU East Bay campuses are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. All CSU East Bay campuses also have vehicles that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the all CSU East Bay campus areas. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures at all CSU East Bay campuses are at risk from severe weather. There are approximately 39 buildings that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still...
be in the millions of dollars. The total replacement costs due to severe weather hazard are $164,768,550 for 30 buildings, and unknown for the remaining nine (9) buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at all CSU East Bay campuses varies throughout the day. As of Fall, 2019, CSU East Bay had 14,705 students and 1,764 faculty and staff. All are at risk from severe weather events, with 16,469 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to CSU East Bay campuses. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU East Bay.

It is evident that CSU East Bay has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.

---

8.4 Social Risk Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU East Bay campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
### Table 8-40: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>
| Which population groups have little/limited support networks if impacted by an event? | - Populations experiencing homelessness  
  - Socially or economically disadvantaged populations  
  - Populations who speak English as a foreign language  
  - International students |

### Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**
In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Strong interest was expressed for developing elements for many of these issues/populations in the different plans but have not yet had the opportunity to do so. It was specifically noted that homelessness, health and wellness and racial equity will be addressed in the emergency plans.

- The group of students who don’t read emails is an issue. They have had to strategize and prioritize because everyone has a different method for preferred contact.
- Digital equity is in the Business Continuity Plan (BCP) not in the EOP and the plan is to leave it on the BCP side.
- Writing a communications plan now. Currently the outreach through alerts is English only.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

Table 8-42: CSU East Bay *Highly Likely, Likely and Possible* Hazards

</tbody>
</table>
Drought

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods. Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states. Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

Earthquake

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread

housing damage and preexisting housing market constraints will make it “extremely
challenging” for the socially and economically vulnerable populations to find alternative
housing near their home communities. Those who utilize interim and irregular housing
for months and years after a disaster are more vulnerable to physical, social, and mental
disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks
and post disaster conditions delay population return and increase outmigration.

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability
to these events and their impacts depends on human behavior and the traditional social
factors such as situational awareness, prior knowledge of hazards, social capital and
decision-making capabilities, as well as increased vulnerability due to social factors, such
as racial and economic disparities.

**Landslides**

Although infrastructural losses are of secondary importance to the risk to humans
themselves, research investigating the vulnerability of people to landslides is rare. The
many reasons for this lack of data are related to the fact that the collapse of occupied
buildings which makes it a function of structural vulnerability and therefore, indirect. The
degree of vulnerability to landslides by an individual considered at high risk, or even the
general populations, also depends on human behavior, including many of the traditional
social factors that are difficult to measure such as situational awareness, prior knowledge
of hazards, and decision-making capabilities.

Landslides can result in primary lifeline failures through the loss of roads or power and
communication lines. Transportation routes are often expensive to clean up, and
prolonged obstruction can disrupt the movement of people and goods. Risk from
landslide relates to earthen and infrastructural losses. The degree of vulnerability to these
events and their impacts depends on human behavior and the traditional social factors
such as situational awareness, prior knowledge of hazards, social capital and decision-
making capabilities, as well as increased vulnerability due to social factors, such as racial
and economic disparities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events,
such as those experienced throughout the state over the recent years. Many businesses

---

https://doi.org/10.3133/sir20175013v3, accessed 0162021

close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. 208 Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old. 209

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: 210 particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs. 211

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas,

---

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

9.1 University Profile

University History

California State University, Fresno (CSU Fresno/ Fresno State University) was founded as the Fresno State Normal School in 1911 as a teacher’s college, and began offering advanced degrees in 1949. Seven years later, the school moved its campus a short distance north to its current location. It became a charter institution of the California State University System in 1961 and changed its name in 1972 to California State University, Fresno. Today, the school includes 10 colleges and is classified as a Doctoral/Professional University by the Carnegie Institute. CSU Fresno is designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

Both the University Cabinet and University Advisory Board operate in advisory capacities to the campus president. The Cabinet is comprised of senior leaders on campus who provide advice to the president in addressing strategic and operational issues and in pursuing new initiatives. The Advisory Board, made up of community members and professionals, assists the University in effectively carrying out its mission, and is used at the discretion of the president to seek counsel and advice as needed.

University Mission

“To boldly educate and empower students for success.”

CSU Fresno outlines four strategic priorities in support of their goals. The priorities are directed towards supporting a sustainable campus environment, developing community partnerships, enhancing teaching and student support services, and attracting talented and diverse faculty and staff.

University Location

The CSU Fresno main campus encompasses 388 acres in the City of Fresno, CA (population 530,000). Located in the San Joaquin Valley, the campus is proximal both to the agricultural regions of California’s Central valley and to the Sierra Nevada Mountains. In addition to the main campus, CSU Fresno manages the University Agricultural Laboratory, a 1,000-acre farm, and 4,500 acres of Sierra foothill rangeland located at the San Joaquin Experimental Range.
University Population

Typically, enrollment at CSU Fresno exceeds 20,000 per semester. In fall 2020, the 25,341-student population was overwhelmingly made up of undergraduate degree seekers, among whom the average age is 21.7. Hispanic students make up 54.9% of all CSU Fresno students, with white students making up the second most populous group at 18.2%. The combined populations of Asian, Pacific Islander, and Native American students make up 12.8% of the total student body. A majority of CSU Fresno undergraduate students are first-generation and full-time, and many are Pell Grant eligible.

In addition to the student population, CSU Fresno is home to 2,533 employees, 58.5% of whom are faculty.

9.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate...

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.
Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

9.3 Hazard Identification and Risk Assessment

Overview of California State University, Fresno History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered XX hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 9-1 (following).

Table 9-1: Hazard Identification Determinations

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- Highly Likely- 76%-100% that the hazard would occur annually.
- Likely- 50%-75% that the hazard would occur annually.
- Possible- 11%-49% that the hazard would occur each annually.
- Unlikely- 0%-10% that the hazard would occur each annually.
**Communicable Disease**

**Description of the Hazard**

Communicable diseases are illnesses that occur due to infectious agents or their toxic products, and are infectious due to their potential of transmission from one person or species to another by a replicating agent.¹ They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions.² The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.³

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague).⁴

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 9-2 below.)

### Descriptions of Identified Communicable Disease Hazards at Fresno State

Fresno State has identified three (3) communicable disease hazards that have had the greatest impact on campus – COVID-19, Meningitis, and Tuberculosis. The following are brief descriptions of the communicable disease hazards at Fresno State.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

(***Source***: Interviews with CSU campus staff at CSU campuses and at CSU Chancellor's Office.)
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.5

**Meningitis**

Meningitis is an inflammation of the fluid and membranes (meninges) surrounding the brain and spinal cord. The swelling from meningitis typically triggers signs and symptoms such as headache, fever and a stiff neck. Early meningitis symptoms may mimic the flu (influenza). Symptoms may develop over several hours or over a few days.

Most cases of meningitis in the United States are caused by a viral infection, but bacterial, parasitic and fungal infections are other causes. Some cases of meningitis improve without treatment in a few weeks. Others can be life-threatening and require emergency antibiotic treatment. Bacterial meningitis is particularly serious and can be fatal within days without prompt antibiotic treatment. Delayed treatment also increases the risk of permanent brain damage or death.6

**Tuberculosis**

Tuberculosis (TB) is a potentially serious infectious disease that mainly affects the lungs. Tuberculosis is caused by bacteria that spread from person to person through

---

microscopic droplets released into the air. This can happen when someone with the untreated, active form of tuberculosis coughs, speaks, sneezes, spits, laughs or sings.

Although tuberculosis is contagious, it’s not easy to catch. It is more likely for someone to get tuberculosis from a close family member or coworker than from a stranger. Most people with active TB who have had appropriate drug treatment for at least two weeks are no longer contagious.

Many strains of tuberculosis resist the drugs most used to treat the disease. People with active tuberculosis must take several types of medications for many months to eradicate the infection and prevent development of antibiotic resistance.7

Location of the Hazard

Communicable diseases have the potential to affect the entire Fresno State planning area equally. As a result, the communicable disease hazard can be found at the Fresno State University campus located in Fresno, CA (Fresno County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) Fresno State are at risk of exposure to the communicable disease hazard.8

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For CSU – Fresno, approximately 5% of its 24,139 enrolled students or 1,207 students reside in student housing.

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory

security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 9-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall into these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

Figure 9-1 Biosafety Levels (BSLs)\(^9\)

![BSL Diagram]

The Extent of Fresno State Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Meningitis and Tuberculosis at Fresno State. Meningitis would be classified at the BSL-2 containment level, while Tuberculosis would be classified at either the BSL-2 or BSL-3 containment level.\(^10\) 11

The Extent of Fresno State COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.\(^{12}\)

**History of the Hazard**

Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Figure 9-3 (below) shows County-level COVID-19 case and mortality data. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Before the start of the fall 2020 semester, Fresno State had 17 cases of COVID-19. As of March 15, 2021, Fresno State is aware of 145 members of the campus community who have tested positive for COVID-19 since the start of the pandemic, and who were on campus during the time when they may have been infected.\(^{13}\)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system (including Fresno State). The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of Fresno State students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including Fresno State) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs

range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 9-4: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 9-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level

---

for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 9-5 Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>Risk Group Level I</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one’s hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>Risk Group Level II</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

17 CDC/National Institutes of Health. *Biosafety in Microbiological and Biomedical Laboratories, 6th Ed.* Print. Retrieved 05.03.2021 from: [https://www.cdc.gov/labs/BMBL.html](https://www.cdc.gov/labs/BMBL.html)
| Risk Group Level III | Anthrax  
West Nile Virus  
SARS Virus (Including COVID-19)  
Tuberculosis  
Typhus  
Yellow Fever  
Hantaviruses  
Avian Flu  
| These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone. |
| Risk Group Level IV | H5N1 (Bird Flu)  
Dengue Hemorrhagic Fever  
Marburg Virus  
Ebola Virus  
Smallpox  
Lassa Fever  
Crimean-Congo Hemorrhagic Fever  
Other Hemorrhagic Diseases  
| These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release. |

**Probability of Future Occurrence of the Hazard**

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.
Table 9-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 6-9: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s system-wide probability ranking (below) reflects the ranking at the individual CSU campus level unless noted otherwise.

### Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at CSU-Fresno.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, the CSU System had 480,541 students and 53,763 faculty and staff.) Each of these persons (including Fresno State’s 24,139 students along with its faculty and staff) is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree in the current COVID-19 pandemic on the Fresno State campus.

### Estimate of Potential Losses

**COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities**

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

---

18 The California State University. Enrollment. Retrieved 05.03.2021 from: [https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx](https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx)

19 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: [https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx](https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx)
At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU-Fresno) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

Economic Impact of COVID-19 Pandemic on CSU Financial Health

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. Several CSU campuses saw refund losses surpass $10 million. See Figure 9-4 below for the economic impact to the Fresno State campus).

Figure 9-3: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs

---

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 9-12.) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

CSU System-Wide Totals: $2,896,693,45

9-21
Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems. See Table 9-13 (below) for the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students)

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).
**Dam and Levee Failure**

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtopping to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

---

Location of the Hazard

Fresno County is home to a variety of flood control facilities and levee systems with most levees found in the east County and most dams found in the foothills and mountains. The San Joaquin River and Kings River drain the Sierra Nevada mountains in eastern Fresno County. Fresno sits between the San Joaquin and Kings Rivers. Dry Creek drains an area between the larger rivers and passing just east of the CSU Fresno campus.

Figure 9-4: Dams and Levees near CSU Fresno

Dry Creek is normally a dry creek providing flood control and drainage. The creek feeds into the Big Dry Creek Reservoir behind the Big Dry Creek Dam before extending through Fresno and eventually to the San Joaquin River east of Fresno. The Big Dry Creek is normally dry but fills during storms causing runoff and is 6 miles to the northeast from the CSU Fresno campus.

The San Joaquin River has a series of dams that are located upstream from the Fresno area. The largest being the Friant Dam holding Millerton Lake 13 miles north of the campus. The Kings River is regulated by the Pine Flat Dam 23 miles east of the campus. The inundation zones for neither of these dams come into proximity of the campus.
Levees have been constructed to protect sections of the banks of the Big Dry Creek Reservoir and sections upstream of Dry Creek. The flood protection areas for these levees are not in proximity to the CSU Fresno campus. There are no levees in the area surrounding the campus. The majority of levees in Fresno County are located in eastern Fresno County along the San Joaquin and Kings Rivers.

Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.

---

28 California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

Table 9-15: Fresno County Dams in Proximity to CSU Fresno

<table>

<tr>
<td>San Joaquin</td>
<td>Millerton</td>
<td>520,500af</td>
<td>High Hazard</td>
</tr>
</tbody>
</table>

The CSU Fresno campus lies within the inundation zone of the Big Dry Creek Dam but is outside of the inundation zones of the Millerton and Pine Flat Dams. In the event of a catastrophic failure of the Big Dry Creek Dam, the CSU Fresno campus is expected to be within the inundation area except for the Save Mart Center. The inundation area is expected to spread water over a broad area of Fresno. However, there are multiple transportation corridors that lie within the dam inundation zone that would compromise access to and from the campus affecting the ability to evacuate, gain access to emergency services, and receive supplies. The roadways expected to become inundated in a dam breach scenario include East Shaw Avenue, North Cedar Avenue, East Barstow Avenue, and State Routes 168, 41, 180, and 99. Based on these conditions, the planning committee ranks the extent of the dam failure hazard as **Moderate**.

**Extent – Levee Failure**

Levees are used along numerous rivers, irrigation channels, and other waterways throughout Fresno County primarily along waterways in the eastern part of the County. The CSU Fresno campus does not lie within a levee flood protected area, although potentially, the campus community will be affected as a breach in other areas of Fresno may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. Based on these conditions, the planning committee ranks the extent of the levee failure hazard on campus as **Low**.

**History of the Hazard**

There are no records of dam or levee failures in areas that present a threat to the CSU Fresno campus. Fresno County has experienced the following dam and levee incidents:

Potential Impacts of the Hazard

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Water inundation of campus police department, campus chiller and boiler facilities, plant operations, all academic buildings, support facilities, and residence halls
- Water inundation of transportation routes into and out of the campus
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs

---

29 Fresno County Multi-Hazard Mitigation Plan, April 2018
Reductions in campus revenues

Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues
Probability of Future Occurrence of the Hazard

The Fresno County Multi-Hazard Mitigation Plan indicates that Fresno County remains at risk from dam and levee failure, however, there have not been any failures of any major facilities. The location of the CSU Fresno campus downstream from the Big Dry Creek Reservoir demonstrates that the potential exists for future dam related failures. The entire campus with the exception of the Save Mart Center resides within the dam inundation zone for the Big Dry Creek Reservoir. There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on historical experience and occurrences, along with dam and levee inspection and maintenance protocols, the probability of future occurrence for both dam and levee failures is **Unlikely**.

Vulnerability to the Hazard

The CSU Fresno campus is subject to the effects of flooding resulting from compromised dams and levees. The Big Dry Creek Dam upstream from the campus presents the potential for significant flooding and damage through much of the Fresno and Clovis area. The Dry Creek and extending irrigation channels are channelized drainages intended to protect the surrounding areas from rises in water level. In the case of dam failure, the amount of time to respond to the needs of the campus community prior to inundation will be limited.

Similarly, any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

The dam inundation zone covers an area 3 miles wide through Fresno and extends downstream towards the CSU Fresno campus. Everyone downstream of the dam in the inundation zone will be vulnerable to the effects of floods and forces of moving water. Additionally, the access routes into campus are inside the inundation zone. The CSU Fresno campus lies outside of areas protected by levees. However, the distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of flood insurance will cause extreme financial burdens on those affected.

Some areas of particular vulnerability on the campus includes:

- Flowing water from the northeast
- Hazardous materials, biological contaminants, agricultural materials, and other contaminant spread by flood waters introduced to the campus.
- Inundated academic buildings
- Chemicals, bottled gases, radioactive materials, biological materials, and explosive compounds stored in campus science labs, chemical storage facilities, Facilities Maintenance Shops, and Engineering Labs
- The Joyce M Huggins Early Education Center (childcare center) is located in the Kremen School of Education and Human Development Building is below grade lower in elevation than street level
- Inundated residence halls
- Inundation to the Equestrian Center, Sheep Unit, Animal Science Pavilion, Horse and Cattle facilities, Swine, and Poultry facilities
- Inundated Mail Services, Mail Center, Shipping and Receiving, and Printing Services on north side of campus
- Inundated University High School

Vulnerability to a dam or levee failure on the CSU Fresno campus will vary depending on the degree of breach or structural failure and when the breach or failure were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $395,965,157. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU Fresno.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the CSU Fresno campus, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam
and levee structures presents a valid danger to downstream locations in the event of an earthquake. The consequences of a dam failure would generate catastrophic results to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.
Drought

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for Fresno State versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified in Fresno, CA and the surrounding region including the Fresno State campus. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.\(^30\)

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout the system-wide CSU planning area and across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire planning equally, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. In addition, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Although such effects have not been reported on the Fresno campus, they remain issues of concern for the campus over the long term.\(^31\)

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the

---

U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

</tbody>
</table>

Fire season lasts year-round; fires occur in typically wet parts of state; burn bans are implemented

Ski and rafting business is low, mountain communities suffer

Orchard removal and well drilling company business increase; panning for gold increases

Low river levels impede fish migration and cause lower survival rates

Wildlife encroach on developed areas; little native food and water is available for bears, which hibernate less

Water sanitation is a concern, reservoir levels drop significantly, surface water is nearly dry, flows are very low; water theft occurs

Wells and aquifer levels decrease; homeowners drill new wells

Water conservation rebate programs increase; water use restrictions are implemented; water transfers increase

Water is inadequate for agriculture, wildlife, and urban needs; reservoirs are extremely low; hydropower is restricted

Fields are left fallow; orchards are removed; vegetable yields are low; honey harvest is small

Fire season is very costly; number of fires and area burned are extensive

Many recreational activities are affected

Fish rescue and relocation begins; pine beetle infestation occurs; forest mortality is high; wetlands dry up; survival of native plants and animals is low; fewer wildflowers bloom; wildlife death is widespread; algae blooms appear

Policy change; agriculture unemployment is high, food aid is needed

Poor air quality affects health; greenhouse gas emissions increase as hydropower production decreases; West Nile Virus outbreaks rise

Water shortages are widespread; surface water is depleted; federal irrigation water deliveries are extremely low; junior water rights are curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor;

### History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous, including the Fresno State footprint. According to the US Drought Monitor, Time Series data, Fresno County (which surrounds the campus) has experienced numerous periods of drought covering about 15 years from 2000-2021, including the severe statewide event from 2012-2019.
According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions has been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

---

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and in Fresno County, including the Fresno State campus planning area:

**2012 – 2017** – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2014-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.

**Potential Impacts of the Hazard**

---

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant impact associated with drought across the Fresno State campus planning area is both the historic and potential reduction in water availability for the municipal area tied to the campus. In fact, on campus water use reductions and recycled water use has taken place and continues to be. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of Fresno State to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of agricultural research crops and field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such.\textsuperscript{40} However, the wildfire hazard is analyzed separately in this plan. See wildfire section later in this section.

In reviewing the occurrences of drought for Fresno County, the City of Fresno and Fresno State campus. the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2014-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to Fresno State the broad geographic extent of the impact includes Fresno County and the Central valley and makes it likely that tree mortality occurred to some degree on the campus. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids.

\textsuperscript{40} CAL FIRE Fire and Resource Assessment Program (FRAP). \textit{2017 Assessment}. Print. Retrieved 05.05.2021 from: \url{https://frap.fire.ca.gov/assessment/}
Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.  

At present, drought related damage to campus buildings and infrastructure at Fresno State has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for Fresno State is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including Fresno State. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Table 9-12: Summary of Drought Impacts on Water Resources

<table>

Runoff | Direct | Warmer temperatures are likely to lead to a shift in peak runoff from spring to winter and a likely decrease in summer base flow
---|---|---
Hydropower | Indirect | Decreased summer flows resulting from earlier snowmelt and a shift in peak runoff could affect hydropower generation during summer months
Precipitation | Direct | Warmer winter temperatures will result in a greater percentage of precipitation falling as rain rather than as snow
Groundwater | Indirect | Reduction in snowpack and extended periods of drought are likely to increase dependency on groundwater

Probability of Future Occurrence of the Hazard

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that Fresno State lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the Fresno State campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the Fresno State planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability.
of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

Vulnerability of Populations

The historical and potential impacts of drought on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the CSU - Fresno campus.

Property Vulnerability

The historical and potential vulnerabilities to drought include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the Fresno State campus.

Natural Environment Vulnerability

Drought vulnerabilities in the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds. The core issue shaping drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment

---

and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for Fresno State’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the city and county of Fresno, and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies and other stakeholders for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

In addition to ground motion, there are several secondary hazards that can result from an earthquake including:

Fault Rupture – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

Liquefaction – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.
**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. Fresno is located in the center of the San Joaquin Valley along the eastern edge at the base of the Sierra Nevada Mountains. In general, fault systems occur to the west and east of Fresno. Throughout the valley the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 75 miles west of the CSU Fresno campus. In addition to the San Andreas Fault, Fresno County is home to or near additional fault systems with the potential to generate strong ground shaking. The Great Valley Fault traverses along the eastern base of the Coastal Range 50 miles east of the CSU Fresno campus. The Ortigalita Fault extends approximately 50 miles in length along the Coastal Range 80 miles east of the CSU Fresno campus. There are additional faults in the Sierra Nevada Mountains east of Fresno. These faults are at least 75 miles from the campus on the opposite side of the mountains.
Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale (Table 9-18 below) was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The
energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

Table 9-14: Modified Mercalli Intensity Scale

</tbody>
</table>

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.
Based on the limited occurrence of earthquakes in the Fresno area, and the location of the campus relatively far from fault systems, the potential for severe impacts still exists due to the presence of 5 active faults, one of which (San Andreas fault) has a 32% probability of occurrence of a 6.7 or greater magnitude event over the next 30 years. As such, the planning committee ranks the extent of the hazard as **Low-Moderate**.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Fresno County also has history of earthquake activity especially on the western side. Fresno County has a limited history of significant earthquakes occurring in the central part of the County including where CSU Fresno is located.

---

47. Fresno County Multi-Hazard Mitigation Plan, April 2018
The May 2, 1983 Coalinga Earthquake caused extensive damage to buildings, bridges, water systems, and critical facilities in Coalinga. Damage caused by the earthquake included 800 buildings destroyed, the commercial sector of Coalinga receiving heavy damage, and schools and hospitals with minor damages. 1,000 people were left homeless and 47 were injured. State and federal disaster declarations were declared (DR-682-CA).

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. A major earthquake in the Fresno area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Fresno could cause injuries or fatalities to members of the campus community or support networks the campus relies on. Older construction methods may enhance the impacts that damages have on buildings and other infrastructure. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Fresno could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Fresno County region limiting immediate assistance that the campus may normally expect.

Local impacts to CSU Fresno campus caused by an earthquake could include:

- Potential hazardous material releases on and off campus
- Infrastructure damage to regional freeway system
- Structural damage to bridges over waterways and flood control channels
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to Dry Creek levees and Big Dry Creek Dam facilities
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

**Probability of Future Occurrence of the Hazard**

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Fresno County fault systems surrounding the Fresno core is included in the following table.

Based on the earthquake shaking potential in the Fresno area, the proximity fault systems to the west and east of Fresno County, the probability of seismic ground shaking generating damage is considered **Possible**.

**Vulnerability to the Hazard**

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region tend to remain to the west along the Coastal Ranges of east in the Sierra Nevada Mountains. Many of these cross major transportation routes potentially reducing the availability of access and the supply chain. However, Fresno likely less vulnerable to the direct effects of earthquake as known fault systems are removed from the area. The geographic location of Fresno sits at the base of river systems that have deposited sediment from the surrounding mountains. In many cases,

---

48 Fresno County Multi-Hazard Mitigation Plan, April 2018
these sediment-based soils are loose and expose the potential for liquefaction. The soils of the area surrounding the campus are described by the Local Hazard Mitigation Plan as generally being not conducive to significant liquefaction due to a high clay content.

The known fault systems generating the threat to Fresno generally exist to the east and west of the city but do not cross into the city including the CSU Fresno campus. The distance and to these surrounding systems help mitigate significant vulnerabilities in the event a seismic event were to occur on those systems. In the event of an earthquake occurring in the region on an unknown system, the potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the CSU Fresno campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the city. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases.

Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with sheltering and care of those unable or unwilling to return to their homes. Damages to the homes of the members of the campus community may place greater demands on campus resources and capabilities in the short-term period following a seismic event.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. Certain campus populations
will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $395,965,157.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the Fresno County region and the CSU Fresno campus. Each of the earthquake generated effects will vary widely based on the
intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, however unlikely, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU Fresno campus and community.

In the event that a major earthquake was to strike along the fault systems surrounding Fresno, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Fresno County region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

Campus infrastructure is vulnerable to severe shaking particularly in areas where the ground is loose or susceptible to liquefaction. Specifically older buildings, masonry constructed buildings, and other structures susceptible to shaking related damage are the most vulnerable. Communication systems, computer networks, and other electronic systems may be vulnerable when overwhelmed by increased demand during emergencies or by shaking related damages.

The campus population is vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Erosion**

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another”. Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading

---

result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable.

Location of the Hazard

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across those areas of the campus with erosion-prone characteristics. For example, erosion has occurred on construction sites and surrounding parking lots and roadways.

Extent of the Hazard

There is no published scale of severity or extent for this geologic hazard. While erosion in the valley area is typically not problematic, erosion hazards are present on steep slopes in the Sierra Nevada mountains and foothills. If conditions are favorable on campus, erosion is likely to occur. However, given some historical occurrence of erosion on campus, the planning committee ranks the extent of this hazard as Moderate.

History of the Hazard

The campus has experienced erosion on construction sites and surrounding parking lots and roadways. The Fresno County Multi-Jurisdictional Hazard Mitigation Plan states that there have been no significant erosion events within the county.51

Potential Impacts of the Hazard

Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

In agricultural areas, the erosion of soil degrades the quality of the soil, which can lead to reduced crop yields.52 At the Paul L. Byrne Memorial University Farm, soil erosion can

51 County of Fresno Office of Emergency Services. Retrieved 2.7.21 from: https://www.co.fresno.ca.us/home/showdocument?id=35154
create significant concerns for agriculture and research. Eroded test plots can negatively impact experiments and tests, resulting in a loss of knowledge and data.

**Probability of Future Occurrence of the Hazard**
Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, the probability of at least a limited degree of erosion taking place somewhere on campus in the future is **High** over the long term.

**Vulnerability to the Hazard**
Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Fresno infrastructure, buildings, and agriculture located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. CSU leadership would consider performing an analysis on specific at-risk buildings, slopes and soil types in the future.

In the wider Fresno community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

**Estimate of Potential Losses**
The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

**Vulnerability Assessment Conclusions**
While the ability to predict future erosion on the CSU Fresno campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**
The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

*Extreme Temperatures (Includes Extreme Cold and Extreme Heat)*

**Heat**

**Description of the Hazard**
What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at
higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.\textsuperscript{53}

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.\textsuperscript{54} As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feel” hotter. The combination of temperature and humidity is known as the heat index.\textsuperscript{55}

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.\textsuperscript{56} In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.\textsuperscript{57}

Location of the Hazard

Extreme heat events are a non-spatial hazard, and may occur anywhere at the Fresno State campus.

Extent of the Hazard

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the low 90s to the high 90s in the City of Fresno. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded in Fresno was 113\textdegree{} F on three successive days in 2006: July 23, July 24, and July 25. This was part of a record-breaking heat wave that affected much of California between July 16 and July 26, 2006. Numerous daily maximum temperature records were set and an all-time record for statewide energy consumption was also reached on July 24 with 50,270 megawatts. More than 100 heat-related deaths were recorded in the state.\textsuperscript{58}

\footnotesize
\textsuperscript{55} Ibid.
Based on average maximum temperatures in the 90’s, five extreme heat events in Fresno from 2006 – present, and on the potential impacts, the planning committee ranks the extent of the hazard as Low to Moderate.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 9-10 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

Figure 9-10: Methodology for Determining Heat Index.

As the heat index rises, so does the potential danger to people and animals. The following table shows the health hazards associated with extreme heat.

Table 9-18: Health Risks Associated with Heat Index

<table>
<thead>
<tr>
<th>Category</th>
<th>Heat Index</th>
<th>Health Hazards</th>
</tr>
</thead>
</table>

Extreme Danger | 130° F or higher | Heat stroke / sunstroke is likely with continued exposure.
---|---|---
Danger | 105° – 129° F | Sunstroke, heat cramps, and/or heat exhaustion is likely with prolonged exposure and/or physical activity.
Extreme Caution | 90° – 104° F | Sunstroke, heat cramps, and/or heat exhaustion is possible with prolonged exposure and/or physical activity.
Caution | 80° – 89° F | Fatigue is possible with prolonged exposure and/or physical activity.

Based on the record of four extreme heat events in Fresno (2008-present), although Fresno County maintains established protocols of providing the public with advanced notice of heat events with directives for mitigating impacts, the planning committee ranks the extent of this hazard as **Moderate**.

**History of the Hazard**

In addition to the 3 days of record high temperatures in 2006 (NCDC data), data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been four additional excessive heat events in Fresno County since 2008.

**July 9, 2008:** This was part of a widespread heat wave that affected much of the state. In Northern California, the heat exacerbated wildfires burning in the region, where hundreds of thousands of acres had already burned.

**September 1, 2017:** Much of the Southwest experienced extreme heat in late August continuing into early September, with many metro areas experiencing record-breaking temperatures.

**June 10, 2019:** This event occurred during one of the hottest heat waves to ever hit California, with temperatures breaking records across the state and much of the Southwest.

**May 26, 2020:** The month of May ranked as one of the hottest on record for multiple cities in California, with average temperatures ranging approximately 2.5 to 5 degrees above normal.

**Potential Impacts of the Hazard**

Fresno State may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which
can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

Two extreme heat events have occurred in Fresno County in the past two years, but just five events since 2006. Therefore, it is Somewhat Likely that the hazard will occur annually, given upward trends due to climate change.

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.61 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

CSU Fresno experiences several hot days each summer, with the potential for extreme heat events. Fall athletic teams may be exposed to extreme heat during summer training and early season games. The campus takes precautions to make cooling and water stations available for athletes and spectators during fall football games when needed. The campus also sponsors training and information on heat stroke and heat exhaustion.

When it comes to staff safety, CSU Fresno allows employees who work outdoors to take more breaks inside or switch to indoor work if available. They are also subject to frequent checks by supervisors to ensure their safety and wellbeing.

Therefore, while this is a hazard that the campus may experience with regularity, the campus has ample familiarity with in order to handle the risks and vulnerabilities.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the CSU Fresno campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), central California has warmed about two degrees on average over the last century, with less rainfall. This may lead to stronger heat events, drought, and an increased risk of wildfires.62

Cold

Description of the Hazard

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.63

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.64 This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underly tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes.65 It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases.66 The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6° F. Hypothermia occurs when your body temperature falls below 95° F.67 As this happens,

66 Ibid.
the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

Location of the Hazard

Extreme cold events are a non-spatial hazard, and may occur throughout the Fresno State campus.

Extent of the Hazard

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in the City of Fresno typically range from the high 30s to low 40s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in Fresno was 18° F on December 23, 1990. Based on hundreds of frost/freeze events and multiple cold/wind chill events as well as five extreme cold/wind chill events from 1996 – present, the planning committee ranks the extent of the hazard as Moderate.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30° F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions. Although Fresno County has experienced frequent frost/freeze events, and five events defined locally as extreme. Although it has not experienced an extreme cold event as defined by the NWS (above, based on the regional climate and its relationship to the economy, frost/freeze events represent a consistently impactful hazard to the county’s agricultural sector, utility services and the local economy in general. Therefore, the planning committee ranks the extent of the hazard as Moderate to High.

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure 9-11 (following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow).

In 2011, the National Weather Service introduced an experimental program that issued warnings for extreme cold events, independent of other severe weather warnings. The test areas included North and South Dakota and Minnesota. However, in 2012, after a single season of use, the program was abandoned, based on reports of confusion among test audiences.69

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, Fresno County has had hundreds of frost/freeze events and multiple cold/wind chill events dating back to 2000. [Records for this hazard were first recorded in 1996]. The county has also had five extreme cold/wind chill events, all within the same two-week period in January-February of 2002.

January 16, 2002
January 22 – 23, 2002

January 29, 2002  

February 1, 2002  

Potential Impacts of the Hazard

Should an extreme cold event occur, Fresno State might experience impacts due to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

Probability of Future Occurrence of the Hazard

The City of Fresno has experienced frequent cold/wind chill/freeze/frost events, and five extreme cold events in 2002. However, these extreme cold events were limited to a single period of time nearly two decades ago Therefore, the probability of freeze/frost events is Highly Likely annually, while more extreme cold events are only Possible on an infrequent basis.

Vulnerability to the Hazard

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more likely to suffer illness or death as a result.\(^{70}\) This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

CSU Fresno is aware of the potential for extreme cold events, and is one of the CSU campuses facing the greatest variance in temperatures.

---

\(^{70}\) Cleveland Clinic. *Hypothermia Can Happen Both Indoors and Outdoors.* Retrieved from:  
https://health.clevelandclinic.org/hypothermia-can-happen-indoors-surprising-facts/  

9-65
Estimate of Potential Losses

Based on the previous historical occurrences of extreme cold events, annualized losses are considered to be negligible. In an extreme cold event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future extreme cold events at the CSU Fresno campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), areas in central California have warmed approximately 2 degrees on average over the last century, with less rainfall. This may lead to fewer frost/freeze events in the future.71

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

Flood

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Floods can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.
Coastal Flooding – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

Atmospheric River

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.

Figure 9-12: Science Behind Atmospheric Rivers

---

72 National Oceanic and Atmospheric Administration, “What are atmospheric rivers?”, https://www.noaa.gov/stories/what-are-atmospheric-rivers
Location of the Hazard

Fresno lies in the heart of the San Joaquin Valley at the base of the Sierra Nevada Mountains. The San Joaquin River, Kings River, and creeks between the rivers have been identified as the primary flood sources for Fresno County. The eastern portions of Fresno County are primarily mountainous terrain of the Sierra Nevada Mountains. The San Joaquin River watershed encompasses 1,720 square miles of drainage above Friant Dam. The watershed receives the majority of its water from snowfall generating 1.86 million acre-feet of surface water fun-off into the San Joaquin River. The Kings River watershed drains an area of 1,544 square miles into the Kings River through southern Fresno County.
The CSU Fresno campus is located 4-5 miles south of the San Joaquin River. The Kings River lies 15 miles to the southeast of the campus. Dry Creek when filled with water drains into the Big Dry Creek Reservoir located 6 miles to the northeast of the campus. Dry Creek continues to drain into a channel that extends through Fresno and Clovis just east of the campus. The majority of the CSU Channel Islands campus sits within a Special Flood Hazard Area (SFHA) Zone X (0.2% of Annual Chance of Flood Hazard) designation on the Flood Insurance Rate Map. The Bob Bennett baseball stadium, Save Mart Center, the Student Recreation Center, and the Save Mart Center parking lot 2 reside in a Zone X: Area of Minimal Flood Risk.

Figure 9-13: Flood Hazard Zones Around CSU Fresno

Extent of the Hazard

The CSU Fresno campus is located mostly in a designated Zone X: 0.2% Annual Chance Flood Hazard. Portions of the eastern and western edges of the campus are located within

a Zone X: Area of Minimal Flood Risk. The access routes into and out of the campus servicing Fresno County locations are found mostly in areas designated as Zone X: 0.2% Annual Chance Flood Hazard. Although comprehensive campus-level flood data is not available, given that 12 Federally Declared flood disasters have occurred in Fresno County over the 31-year period from 1986 - 2017, along with minor annual flood events in winter months, the planning committee ranks the extent of the flood hazard on campus as Moderate.

Another consideration for the ranking is that the CSU Fresno campus lies outside of a levee flood protected area. Levees protect areas at the base of the foothills along the Big Dry Creek flood control system and along the San Joaquin and Kings River systems. This specific hazard does not substantially alter the ability of the campus to maintain operations as the distance to levee protected channels exceeds the protection zones.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 9-19: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised maps in place on Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
</tbody>
</table>
Zone AE 1% Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, base flood elevations derived from detailed analyses are shown at selected intervals within these zones.

Zone AH 1% Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between one and three feet.

Zone AO 1% Areas with a 1% annual chance of flooding, where shallow flooding average depths are between one and three feet.

Zone X (shaded) 0.2% Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.

Zone X (unshaded) Undetermined Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No Base Flood Elevation or depths are shown within this zone.

History of the Hazard

Flooding in Fresno and the broader Fresno County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and numerous fatalities. The following provides insight into information of past flooding events that are significant to the CSU Fresno campus.

### Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means

---

74 Fresno County Multi-Hazard Mitigation Plan, April 2018
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Additionally, individuals who are unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

**Probability of Future Occurrence of the Hazard**

Fresno County is determined to be at high risk of flooding for events less than 100-year flood events and moderate risk of 100-year flood events. However, the location of the CSU Fresno campus within a Zone X Flood Hazard Zone (Area of Minimal Flooding) demonstrates that the probability of future occurrence for flooding on campus is Unlikely on an annual basis, but Possible over the long term.

**Vulnerability to the Hazard**

The CSU Fresno campus is subject to the effects of small-scale, isolated flooding or ponding resulting primarily from localized flooding from excessive precipitation and isolated strong storms. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of Fresno due to overflow or damage to flood control systems such as the Big Dry Creek System. The flood control channels and drainage systems that surround the campus have limited storage or volume capacities.

Vulnerability to flooding on the CSU Fresno campus will vary depending on when the flood were to occur and the location of people or assets located within any low lying areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community may become trapped on campus depending on the level of flooding occurring on surface streets. However, in region-wide events this
vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

CSU Fresno is in proximity to agricultural facilities, including CSU Fresno operated facilities, supporting the planting of crops and management of livestock. When these facilities are inundated with flood water, the potential for release of contaminants, fertilizers, and other chemicals exists presenting possible exposures to individuals from the campus community. These facilities additionally surround the Fresno community as agriculture plays a dominant role in the region.

Some campus buildings and infrastructure in low lying areas might be vulnerable to large-scale flooding if it reaches the university. Campus utilities and communication capabilities could be impacted by flood waters rendering them disabled. A flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls, if located in low lying area, may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. In such areas, flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $395,965,157. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. The proximity to the Dry Creek further presents an additional flood hazard risk factor for the campus.

As discussed above, those factors creating the potential for flooding on campus and in the surrounding area generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the campus community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.
HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Hazardous Materials**

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment. Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.”

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident**

A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident**

A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident**

A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

75 2018 State of California Hazard Mitigation Plan, section 9.2
- **Safety hazards** (fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards** (carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs)**

During the past two decades, increasing attention has been given to hazardous materials releases resulting from *Natechs* or a natural disaster event that triggers a technological hazard event. As pointed out by Lindell and Perry (1996), Young, Balluz, and Malilay (2004), and Steinburg, Sengul, and Cruz (2008), natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. The planning committee indicates that chemicals are located in the science lab, but otherwise no known hazardous materials are present on campus. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city and county of Fresno, and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

However, for the CSU – Fresno planning committee, although small chemical spills have taken place on campus, and hazardous materials are limited to chemicals in the science building, gas pipelines and hazardous waste sites are located close to the campus. Based on these factors along with the types and levels of hazardous materials in the larger community, it is prudent to rank the extent of the hazard for the CSU – Fresno campus as Moderate, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

76 California Department of Industrial Relations. Worker Safety and Health During Fire Cleanup. Retrieved on 06.16.2021 from: [http://www.dir.ca.gov/dosh/wildfire/Worker-Health-and-Safety-During-Fire-Cleanup.html](http://www.dir.ca.gov/dosh/wildfire/Worker-Health-and-Safety-During-Fire-Cleanup.html)

77 2018 State of California Hazard Mitigation Plan, section 9.2
For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.78

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

For more details on specific hazmat events, please refer to the local, county and/or multi-jurisdictional hazard mitigation plans where CSU campuses are located at: https://www.caloes.ca.gov/cal-oes-divisions/hazard-mitigation/hazard-mitigation-planning/local-hazard-mitigation-program

According to the campus planning committee, small chemical spills have taken place on the CSU – Fresno campus but did not result in the need for evacuation.

Potential Impact of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin.

Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – Fresno campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

Potential Impact of the Hazard

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Fresno) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

79 2018 California State Hazard Mitigation Plan, section 9.2.
80 2018 California State Hazard Mitigation Plan, section 9.2.
Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the CSU – Fresno campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Moderate because the CSU – Fresno campus has chemicals in the science lab, and it has experienced chemical spills in recent years. That said, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the CSU – Fresno campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: chemicals are present in the science lab, and gas pipelines and hazardous waste sites are fairly close to the campus footprint. Gases and chemicals or hazardous waste, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Fresno leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Fresno) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the
natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Fresno County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Fresno campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – Fresno planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

Landslide

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure.81 These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation

______________________________

by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life. Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within the deposition zone and can result in downstream flooding. Post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 9-15. Based on Figure 9-15 (below), the Fresno State campus is located in an area with a very low degree of susceptibility to landslide.

Figure 9-14: CSU-Fresno Landslide Susceptibility

---

### Extent of the Hazard

The geographic extent of landslide hazards is limited to foothill and mountain areas and areas where inadequate ground cover accelerates erosion. Those areas have limited population and landslides are not likely to occur in the valley due to its flat topography. However, small slides may occur along steep streambanks in the valley. Additionally, the indirect impacts of landslides in the region may cover a larger geographical extent. Based on the campus’ location in a low-risk landslide hazard zone, and no history of impacts on or near the campus, the planning committee ranks the extent of the landslide hazard for the campus as **Low**.

### History of the Hazard

FEMA declared two major disasters involving landslides, mudslides, or mud flows in Fresno County in 1993 and 1995. NOAA recorded 24 occurrences of debris flow in Fresno County from 2005 to 2019. Several of these occurred in the Southern Sierra Nevada foothills. No landslides have occurred on the campus.

### Potential Impacts of the Hazard
CSU Fresno may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly affect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

**Probability of Future Occurrence of the Hazard**

Slope failures are also often triggered by other natural hazards such as heavy rainfall or earthquakes, so landslide frequency is somewhat related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred infrequently in the City Fresno and, therefore, are not likely to occur in the future. Given the location of the campus in a low-risk zone, landslide zone, and the infrequent occurrence of landslides in Fresno, the planning committee ranks the probability of the landslide hazard for the campus as **Unlikely**.

**Vulnerability to the Hazard**

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. The Fresno State campus exhibits very few, if any, building and infrastructure or transportation route vulnerabilities due to its location. See the landslide location map in relation to the campus along with landslide severity zones identified.

Any population proximal to a landslide when it occurs is vulnerable to its impacts.

**Estimate of Potential Losses**

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Fresno.

**Vulnerability Assessment Conclusions**
Landslides are not likely to impact the campus, though indirect impacts to campus transportation and utilities are possible. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**

The ability to predict future landslides at the CSU Fresno campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.84

**Power Outage**

**Description of the Hazard**

The City of Fresno is a large community located in Fresno County that lies at the center of the San Joaquin Valley, the southern region of the Central Valley of California. The city has become an economic hub of Fresno County and the San Joaquin Valley, with much of the surrounding areas in the Metropolitan Fresno region predominantly tied to large-scale agricultural production, much of which relies on electrical power.

Most aspects of modern life, rely on the near-continuous availability of utilities, such as electricity, water, and natural gas. Fresno State University is located in the fifth most populated city in California. An interruption in the supply or distribution of these services can leave highly populated areas, like Fresno, without basic services, such as electricity or sanitation. These interruptions can produce cascading effects from other hazards, such as major windstorms, leading to intentional disruptions of transmission lines due to safety concerns.

Fresno State can be affected by a power outage event and disrupt day-to-day operations of the campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the campus’s thoroughfares and boulevards surrounding the campus. Additionally, impacts can occur to the surrounding campus community by forcing temporary closures of businesses and community resources.

Overall, a severe outage to Fresno County or the City of Fresno would directly affect the campus and the community creating social, economic and (potentially) health and safety impacts.

An electric power disruptions and outages fall into two categories: *intentional and unintentional*.

The four types of intentional disruptions:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, as a hazard, it has the potential to occur and affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities, and the California Independent System Operator (CAISO) is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities. CAISO is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly. Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. However, given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as **Moderate**.

**History of the Hazard**

Fresno State University has experienced power outages for various reasons. The university worked with the community’s local electric utility company to restore energy to the campus for its facilities, assets, resident halls, and classrooms. The following are examples of power outage events experienced over the last 8 years:

- **May 15, 2015;** Fresno State University experienced a power outage. Commencement ceremonies scheduled for that evening took place as scheduled at 6pm.
- **April 15, 2016;** A windstorm early in the morning caused power outages throughout the area, including Fresno State University. The campus remained open and continued to operate. The power outage affected multiple buildings on campus including Student Housing Complex, Chisholm Hall, Monterey Hall, Matador Bookstore, Klotz Student Health Center, Valley Performing Arts Center, Cypress Hall, Nordhoff Hall, Manzanita Hall, Santa Susana Hall, parking lots/structures B1, B2, B3, G3, as well as KCSN. Students in affected areas were able to report to class for further instruction, and employees report to their department.
- **October 6, 2016;** A power outage affected Sierra Hall, Redwood Hall, Manzanita Hall, and the Oviatt library. The power outage was not unique to the University. The Fresno community was affected by the power outage.
- **2013;** Power supply issue occurred over Winter Break. Campus only closed 1-day due to time of year. Vulnerable to rolling blackouts.

**Potential Impacts of the Hazard**

Residents, commerce, and government infrastructure rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations. Electrical power most likely is the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people...
and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

**Climate Change and Energy Shortage**

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs yearly during the same seasonal periods of temperature variance throughout the calendar year. That said, 4 recorded power outage events took place on campus in eight years (2013-2021). As such, the probability ranking for the campus is **Likely**.

However, climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations.
A power outage could affect the entire area of the campus, including the Fresno State athletic fields, classrooms resident halls, administrative offices, virtual, telephonic and radio communications, and loss of lighting in campus parking structures, creating a cascading hazard for commuters as they depart from or arrive to campus in the evening. Additionally, the university is located within proximity of highly utilized thoroughfares for the transportation of goods to Northeast California, Northern California and down to Southern within one of the busiest areas of the Valley. A power outage would create traffic hazards around the exterior of the campus and the Sierra National Forest via Highway 168, and Sequoia and Kings Canyon National Parks via Highway 180.

Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

**Estimate of Potential Losses**

The data provided by Fresno State does not report any value for potential losses due to power outage.

**Vulnerability Assessment Conclusions**

The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Channel Islands. Safety and operations protocols center on the following “direct impact” set of concerns:

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and, to maintain a safe campus environment and visibility during nighttime hours. The vulnerable population (especially students with physical disabilities) may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors, and locks and lights may impede on a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

**Identified Data Limitations**

Fresno State did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
**Volcano (Associated Air Quality)**

**Description of the Hazard**

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location”.

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

**Location of the Hazard**

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. A significant portion of Fresno County is located within a volcanic hazard zone.

**Extent of the Hazard**

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. A significant portion of Fresno County is within the Long Valley volcanic hazard zone and ashfall may directly or indirectly impact CSU Fresno. As such, the planning committee ranks the extent of the hazard for the campus as **Moderate**.

---

Volcano Hazard Zones in California
Dashed lines enclose areas where 2 inches or more of ashfall are possible. Hazard maps are dynamic and updated periodically as research adds new information.87

History of the Hazard
No historical eruption events in California have affected the campus. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago. Historically, there have been few losses from volcanic eruptions in the state.

Potential Impacts of the Hazard
The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Fresno is not proximal to an active volcano, only the potential impacts of ashfall and

gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Fresno.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard
The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. In any given year, the Long Valley volcanic region has a 1 percent chance of eruption. As such, the annual probability of future occurrence for the campus is ranked by the committee as Possible.

Vulnerability to the Hazard
Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Fresno, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

CSU Fresno is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of a future eruption in the Long Valley volcanic region is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain.90 These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

90 State of California Hazard Mitigation Plan, September 2018
California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. Fresno is located in the central portion of the San Joaquin Valley along the at the base of the southern Sierra Nevada Mountains. In general, areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur to the east of Fresno. These areas surrounding the valley are topographically diverse,
contain heavier vegetative fuels, and often have residential development interspersed. The land in the San Joaquin Valley where the CSU Fresno campus is located, is largely agricultural, urban, or otherwise developed.

The CSU Fresno campus is located in the northwestern portion of the City of Fresno and next to the City of Clovis. The area immediately surrounding the campus is predominately developed with residential and commercial land uses. Agricultural fields exist to the north of the campus. The campus is established in 6 miles from downtown Fresno. Fire Hazard Severity Zones are found 6-8 miles to the north and east towards the foothills. High Fire Hazard Severity Zones are found along the length of the foothills to the Sierra Nevada Mountains. Agricultural areas with extensive crop and orchard production are located extensively north, west, and south of the city. There are no areas in proximity to the campus that present direct threats to wildfire.

However, the CSU Fresno campus is located in the Central Valley surrounded by the mountains and extensive areas of fire hazards. These mountain ranges host three national forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the valley in the right weather conditions. The geography of the Central Valley creates a topography that captures air pollutants including smoke within the surrounding mountains and the development of inversion layers. The CSU Fresno campus is located in a region in which is vulnerable to wildfire smoke that can saturate the air around the campus.
Extent of the Hazard

The area immediately surrounding the CSU Fresno campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, fires are likely to occur in areas close enough to the campus that generate substantial amounts of smoke that could envelop the campus in the right atmospheric conditions. This will especially be the case in weather conditions creating strong offshore winds. The potential for this impact has been demonstrated during the summers of 2018, 2019, and 2020 as fires burned across the state and spread smoke over vast distances. Fires burning

---

outside of the Fresno County region have the potential to distribute smoke onto the CSU Fresno campus.

Given the (above) factors, and that Fresno County has a long history of wildfire activity primarily in the foothills and mountains of the Sierra Nevada and Coastal Range Mountains, the planning committee ranks the extent of the hazard as **Moderate**.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

**Table 9-22: National Fire Danger Rating System**

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel -- especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke.

The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Fresno County also has a long history of wildfire activity primarily in the foothills and mountains of the Sierra Nevada and Coastal Range Mountains. Wildfires occurring in Fresno County have resulted in hundreds of thousands of acres burned and millions of dollars in damages.

The area immediately surrounding the CSU Fresno campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Fresno campus has experienced multiple days of poor air quality due to fires burning in the Sierra Nevada and Coastal Range Mountains. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Fresno County. CSU Fresno personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

Potential Impacts of the Hazard

The location of the CSU Fresno campus surrounded by areas of urban development removed from areas with a fire hazard places a minimal direct threat from wildfire to the campus. The potential impacts to wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets

---

94 Fresno County Multi-Hazard Mitigation Plan, April 2018
Air conditioning systems overwhelmed
Greater demands on air filtration systems
Greater demands on healthcare systems
Reduced outdoor work productivity
Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Fresno County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the wildfire threat potential in the area surrounding the CSU Fresno campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered Unlikely.

Based on the wildfire threat potential in the area surrounding the Fresno region, including the volume of areas in elevated Fire Hazard Severity Zones surrounding the San Joaquin Valley, the probability of wildfire generated smoke impacts to air quality is considered Possible.

Vulnerability to the Hazard

The CSU Fresno campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban/suburban area of Fresno. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of Fresno. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.
Some areas of particular vulnerability on the campus includes:

- Students and staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC or do not have HVAC will cause limitations in filtering of air during smoke filled days
- Air pollution effects to animals housed on the campus
- Power outages or brownouts during days with high levels of smoke will limit shelter in place options during heat events in summer.

The greater concerns regarding vulnerabilities to wildfire on CSU Fresno are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the San Joaquin Valley even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Fresno students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU Fresno campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.
Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $395,965,157. However due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in the mountains surrounding Fresno County; however, wildfire incidents do not pose a direct risk to the CSU Fresno campus. The suburban location of the CSU Fresno campus surrounded by densely developed residential and commercial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The students, faculty, and staff of CSU Fresno who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the campus. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.

Additionally, the topography and weather patterns of Central California often creates conditions that allows for smoke filled air to linger in the Central Valley with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains and forests some distance away that generate tremendous quantities of smoke present...
tremendous health related vulnerabilities to members of the campus community. The campus community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

Severe Weather (Wind, Tornado, Hail, Lightning)

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding.\(^{95}\) According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”\(^{96}\)

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to

normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU Fresno.

**Regional Climate Influences on Severe Weather across California**

Most of the weather in California is influenced by the wet-winter/dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.
While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU Fresno), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.\textsuperscript{103}

**Types of Storms in California**

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.\textsuperscript{104} The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.\textsuperscript{105} These storms affect (in varying degrees) all CSU campuses, including CSU Fresno.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{106} Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.\textsuperscript{107} Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{108} **Severe thunderstorms** are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\textsuperscript{109, 110}

\textsuperscript{103} Retrieved on 07.17.2021 from [https://wrcc.dri.edu/Climate/narrative_ca.php](https://wrcc.dri.edu/Climate/narrative_ca.php)
\textsuperscript{106} Retrieved on 07.14.2021 from [https://www.weather.gov/phi/ThunderstormDefinition](https://www.weather.gov/phi/ThunderstormDefinition)
\textsuperscript{109} Retrieved on 07.15.2021 from [https://www.noaa.gov/explainers/severe-storms](https://www.noaa.gov/explainers/severe-storms)
\textsuperscript{110} Retrieved on 07.15.2021 from [https://www.weather.gov/safety/thunderstorm](https://www.weather.gov/safety/thunderstorm)
- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.111

- **Wind storm**: marked by high wind with little or no precipitation.112

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.113

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.114

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.115

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.116

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: *wind hazards* (including **tornadoes**), **hail**, and **lightning**. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind,

---

tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\(^{117}\) Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”\(^{118}\)

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU Fresno).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\(^{119}\)

**Strong Winds**

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\(^{120}\)

**Thunderstorm Winds**

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50

\(^{118}\) Retrieved on 07.15.2021 from https://forecast.weather.gov/glossary.php?word=wind%20gust

\(^{120}\) Retrieved on 07.17.2021 from https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf
knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\textsuperscript{121}

Please note: \textbf{Straight-line wind} is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\textsuperscript{122} However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

\textbf{Tornadoes}

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\textsuperscript{123} This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\textsuperscript{124} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{125}

\textbf{Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.}

\textbf{Santa Ana Winds}. A type of wind hazard that is peculiar to Southern California is called a \textit{Santa Ana Wind}. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{126} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{127} (Note: The Wildfire hazard is profiled elsewhere in this document.)

\textsuperscript{122} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/
\textsuperscript{123} Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/
\textsuperscript{124} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/
\textsuperscript{125} Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions
Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

Figure 9-18: What Drives a Santa Ana Wind?  

---

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.  

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of
this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.130 131 132

Hail

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.133 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.134

Lightning

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.135

The discharge may occur within or between clouds, between the cloud and air, between a
cloud and the ground, or between the ground and a cloud.\textsuperscript{136} Lightning that is produced
from thunderstorms in which precipitation evaporates before reaching the ground is
called “dry lightning.”

\textbf{Location of the Hazard}
Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system,
including on the CSU Fresno campus. No one area of the campus – or of the surrounding
community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind
events (as a sub-category of the severe weather hazard). Santa Ana winds occur in
Southern California, Diablo winds occur in North-Central California, and Sundowner
winds occur almost exclusively in Santa Barbara County, California.

\textbf{Extent of the Hazard}
Severe weather hazards are non-spatial hazards that potentially affect all CSU Fresno
campus areas equally. However, the smallest geographic unit of measurement for almost
all official severe weather event data is at the county level. Because the severe weather
data used do not exist at the campus level, it is assumed that the same (or similar) severe
weather risks to CSU Fresno reflect those of the surrounding community and County. As
a result, all assets and people at CSU Fresno are at risk from the effects of severe weather
and can expect to experience at least some (or the complete range of) endemic severe
weather hazards. In consideration of the campus’ design, layout, and operations, the
severe weather history and degree of severity in the Fresno area, and the history and
degree of severity of each severe weather sub-type identified by the extent scales
(below), the campus planning committee ranks the overall extent of the Severe Weather
hazard as \textbf{MODERATE}. See each sub-hazard below for the planning committee’s sub-type
extent ranking.

\textit{Wind Hazard: Non-Rotational}

The Beaufort Scale is an empirical measure that relates wind speed to observed
conditions at sea or on land. Its full name is the Beaufort wind force scale.\textsuperscript{137} First
developed in 1805, it is still used today to estimate wind strengths.\textsuperscript{138}

\textsuperscript{137} Retrieved on 07.15.2021 from https://www.rmets.org/resource/beaufort-scale

</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.
**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.¹⁴⁰

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the **date** that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 9-26: Fujita Tornado Scale (Pre-February 2007) ¹⁴¹

</tbody>
</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms. That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light*, *medium*, or *heavy* according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;

- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;

- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

History of the Hazard

Severe weather hazards have been an annual occurrence in Fresno County and on the CSU Fresno campus. Historical data for these hazards are presented below.

Historical Storm Data Collection: NCEI Storm Events Database

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.152 For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.153 To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Fresno County since 1996.154 Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.155

- **High Wind:** at least 102 events, or approximately 4.03 events per year156

---

---

9-124
**Strong Wind:** at least 194 events, or 7.66 events per year\(^{157}\)

**Thunderstorm Wind:** at least 49 events, or approximately 1.93 events per year\(^{158}\)

**All Wind Hazard events** (excluding Tornadoes): at least 343 events, or approximately 13.5 events per year.\(^{159}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Fresno County, there have been at least 343 wind hazard events since 1996, excluding tornadoes.\(^{160}\) That translates to an approximate average historical frequency of occurrence of **13.54** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 345 events) and simultaneous Database searches of all severe weather hazard events (i.e., 343 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Fresno County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{161}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 343 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Fresno County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Fresno County has experienced since 1996 have been costly. There have been 1 death and 20 injuries, and property and crop damage estimates have totaled approximately $217,636,000 and $2,751,000, respectively.162

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 17 reported events of tornadoes in Fresno County, which translates to approximately 0.67 tornado events per year.163

The vast majority of tornado reports in Fresno County since 1996 have been of tornadoes with a severity rating of F0/EF0. Three (3) of the tornadoes reported in has been rated F1/EF1 or higher (they were all F1/EF1 tornadoes); that translates to approximately 0.12 events of F1/EF1 tornadoes that have occurred per year in Fresno County.164

**Historical Tornado Hazard Losses for Fresno County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Fresno County has experienced since 1996 have been costly. While there have been no deaths or injuries, property damage estimates have totaled approximately $781,000; crop damage estimates of $26,000 have also been reported.165 (Note: Two (2) of the F1/EF1 tornado events that occurred in Fresno County caused approximately $600,000 in property losses.)

**Hail**

165 National Climatic Data Center. Storm Events Database. Retrieved on 07.29.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29&Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=FRESNO%3A19&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA
Information from the NCEI Storm Events Database indicates that since 1996, there have been 78 reported events of hail in Fresno County, which translates to approximately **3.08** hail events per year.\(^{166}\) (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 79 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Fresno County. The origin of this discrepancy is unknown at this time.)

**Historical Hail Hazard Losses for Fresno County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Fresno County has experienced since 1996 have been costly. While there have been no deaths, there have been 13 injuries, and property damage estimates have totaled approximately **$60,500.**\(^ {167}\) Hail hazard events have been especially costly to Fresno County’s agricultural sector, generating **$95,385,000** in estimated crop damages since 1996.\(^ {168}\) (Note: The San Diego County hail event that was included erroneously in the search results for hail events in Fresno County accounted for five (5) injuries and a comparatively small amount (approximately 3.15%) of the total crop damage estimates presented in the search results for Fresno County.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 34 reported event(s) of lightning in Fresno County, which translates to approximately **1.34** lightning hazard events per year.\(^ {169}\)

**Historical Lightning Hazard Losses for Fresno County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Fresno County has experienced since 1996 have been costly. While there have been no deaths there have been 3 injuries, and property and crop damage estimates have totaled approximately $1,768,000 and $300,000, respectively.\textsuperscript{170}

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

Information obtained from the NCEI Storm Events Database indicates that there have been 472 occurrences of the severe weather hazard in Fresno County. This translates to \textbf{18.63} severe weather hazard occurrences per year.\textsuperscript{171}

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 473 events) and simultaneous Database searches of all severe weather hazard events (i.e., 472 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Fresno County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{172} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 472 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Fresno County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Fresno County has experienced since 1996 have been costly. There have been 1 death and 31 injuries, and property and crop damage estimates have totaled approximately $220,245,000 and $98,162,000, respectively.\textsuperscript{173} \textit{It is important to note that for all Fresno County severe weather hazard events recorded on the Storm Events Database, both wind and hail hazard events have accounted for all death and injuries. Wind hazard events have accounted for almost all (i.e., 98.8%) reported property damage, while hail hazard events have accounted for almost all (i.e., 97.2%) crop losses.}

**Wind Hazards Not Included in the NCEI Storm Events Database**

\textit{Santa Ana Winds}

\textsuperscript{170} National Climatic Data Center. Storm Events Database. \textsuperscript{173} National Climatic Data Center. Storm Events Database. Retrieved on 07.29.2021 from
Santa Ana wind events occur at least twice per month from October through April.\textsuperscript{174} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textit{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6 days accounting for 90\% of all occurrences. The remaining 10\% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{175 176}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Diablo Winds

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.  

---

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{180}

Figure 9-20: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\textsuperscript{181}

**Sundowner Winds**

Strong sundowner wind events occur approximately \textbf{2-3 times per year}. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\textsuperscript{182}

**Historical Frequency of All Severe Weather Hazards**

Table below shows the average historical frequency of severe weather hazard events for Fresno County since 1996.)

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within CSU Fresno campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU Fresno campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.
Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

According to the 2018 Fresno County Multi-Jurisdictional Hazard Mitigation Plan (MJHMP), wind hazards (excluding tornadoes) are considered to be of medium significance, and therefore to have a moderate impact on the County and (by extension) the CSU Fresno campus.  

Tornadoes are considered to be of low significance, and therefore to have a minimal impact on the County and (by extension) the CSU Fresno campus.

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

According to the 2018 Fresno County Multi-Jurisdictional Hazard Mitigation Plan (MJHMP), hail hazards are considered to be of low significance, and therefore to have a minimal impact on the County and (by extension) the CSU Fresno campus.

**Lightning**

Lightning strikes the United States about 20-25 million times a year. Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured. Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year. (Commercial claim payouts for lightning losses for the U.S. were not available.)

---

According to the 2018 Fresno County Multi-Jurisdictional Hazard Mitigation Plan (MJHMP), lightning hazards are considered to be of low significance, and therefore to have a minimal impact on the County and (by extension) the CSU Fresno campus.\textsuperscript{189}

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The 2018 Fresno County Multi-Jurisdictional Hazard Mitigation Plan (MJHMP) states that there is a near 100\% chance that some of the severe weather hazards profiled above for Fresno County (i.e., hail and lightning) will occur in the next year, a 10-100\% chance that wind hazards will occur in the next year, and a 1-10\% chance that a tornado will occur in the next year.\textsuperscript{190} Also, according to the NCEI Storm Events Database, some of these same severe weather hazards have occurred in Fresno County at least once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Fresno campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU Fresno campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2018 Fresno County Multi-Jurisdictional Hazard Mitigation Plan (MJHMP) and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU Fresno campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU Fresno is **HIGHLY LIKELY**. See Table below for probabilities of future occurrence for component severe weather hazards for Fresno County and the CSU Fresno campus.

**Table 9-31: Severe Weather Hazard Probabilities of Future Occurrence for Fresno County and CSU Fresno**

</tbody>
</table>

**Note:** The Diablo and Sundowner wind hazards are not present in Fresno County, and therefore are not rated for probability of future occurrence. They are included here for information purposes only.

**Vulnerability to the Hazard**

People, structures, and assets on the CSU Fresno campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The CSU Fresno campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

**Estimate of Potential Losses**

Severe weather is a non-spatial hazard that affects the entire CSU Fresno campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within the CSU Fresno campus are at risk from severe weather. There are approximately 116 buildings on the main campus that could be damaged by wind, hail,
and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $395,965,157 for 107 buildings, and unknown for nine (9) buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at the CSU Fresno campus varies throughout the day. As of Fall, 2019, CSU Fresno had 24,139 students and 2,534 faculty and staff; all are at risk from severe weather events, with 26,673 being directly vulnerable in this scenario.¹⁹¹

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to the CSU Fresno campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU Fresno.

It is evident that the CSU Fresno campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.

9.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Fresno campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
Table 9-32: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
</table>
| Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning? | • Commuter students and employees  
• First generation students  
• Populations without reliable transportation or technology |
| Which population groups are most difficult to reach in an event?         | N/A                                                                             |
| Which population groups have little/limited support networks if impacted by an event? | N/A                                                                             |

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (housing insecurity), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (undocumented, DACA, etc.), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as Very High, High, Medium, Low
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as Yes, No, In Progress, NA

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees,
the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Fresno is a Commuter campus with many coming 50 miles one way.
- Major of students are first generation college students and may not have support if significantly impacted so there is a lot of vulnerability; not a lot of resources in transportation, technology, that supports their focus on school.
- Mental health concerns and with a huge increase during COVID.
- Twitter platform-driven campus
- Great dept called the Cross Cultural and Gender Center with programs and resources for LGBTQI students with quite a few panels and discussions for resources.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted
on the impacts of hazards, not all linkages have been documented or published, and
detail for finding them are beyond the scope of this assessment. It’s important to note,
the intersectional nature of what makes an individual’s personal experience and resilience
to an event is played out by unique factors for that individual or population. The nuanced
social vulnerabilities often come from the social and physical environment in which a
person is embedded.

In order to aid in further assessing campus resilience, below is a general description of
the known impacts. From some hazards, the descriptions are robust, while others are
only brief introductions.

</table>
**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\(^{192}\) Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\(^{193}\) Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread

housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.\textsuperscript{194}

\textbf{Erosion}

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

\textbf{Extreme Temps}

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

\textbf{Cold}

Research shows that excess morbidity and mortality occurs during cold weather periods. We critically reviewed evidence relating temperature variability, health outcomes, and adaptation strategies to cold weather. Health outcomes included cardiovascular-, respiratory-, cerebrovascular-, and all-cause morbidity and mortality. Individual and contextual risk factors were assessed to highlight associations between individual- and neighborhood-level characteristics that contribute to a person’s vulnerability to variability in cold weather events.

Skin exposure to cold weather may render one susceptible to adverse health outcomes.\textsuperscript{195} Respiratory tract infections are more likely to occur during periods of low temperatures and low humidity. Socioeconomic indicators related to morbidity and mortality do not appear to strongly contribute to a person’s susceptibility to cold weather.

\textsuperscript{195} Pozos RS, Danzl D. Human physiological responses to cold stress and hypothermia. \textit{Medical aspects of harsh environments}. 2001;1:351–82
However, the role of socioeconomic status is not clear as some evidence implies that income disparities and fuel poverty contribute to cold-related mortality.  

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices. This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underly tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes. It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases. The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6°F. Hypothermia occurs when your body temperature falls below 95°F. As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Heat

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

196 Excess winter mortality in Europe: a cross country analysis identifying key risk factors.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.  

**Flood**

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse

impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. 198

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural heath and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, anger, sadness and grief. 199 Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

**Hazardous Materials**

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease.\(^{200}\) Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.\(^{201}\)

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

\(^{200}\) [https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/](https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/)

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.

**Hazard Mitigation and Emergency Management Planning**

---

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

10.1 University Profile

University History

California State University, Fullerton (CSU Fullerton) was founded in 1959 as the Orange County State College. Following name changes in 1962 and 1964, the school made its final name change to California State University, Fullerton in 1972. It has the largest student body and graduate student body of the California State University system. Today, the school includes eight colleges and is classed as a Doctoral/Research College by the Carnegie Institute. It is a federally recognized Hispanic-Serving Institution and has been selected by the Carnegie Foundation for Distinctive Community Engagement. CSU Fullerton is designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The Academic Senate develops policy on academic curriculum, standards, and criteria for faculty performance and other matters. If a policy created by the Academic Senate is approved by the president, it becomes university policy.

University Mission

“Learning is preeminent at California State University, Fullerton. We aspire to combine the best qualities of teaching and research universities where actively engaged students, faculty and staff work in close collaboration to expand knowledge.

We are a comprehensive, regional university with a global outlook, located in Orange County, a technologically rich and culturally vibrant area of metropolitan Los Angeles. Our expertise and diversity serve as a distinctive resource and catalyst for partnership with public and private organizations. We strive to be a center of activity essential to the intellectual, cultural and economic development of our region.”

CSU Fullerton outlines several goals in support of their mission. These priorities center on the preeminence of and quality of learning, enhancing collaborative approaches, creating an environment supportive of all students, and expanding community connections.
University Location

The 241-acre CSU Fullerton campus is located on the site of former citrus groves in the northeast section of Fullerton, CA. Fullerton, a city of approximately 140,000, is located approximately 25 miles southeast of downtown Los Angeles and 11 miles northeast of the Pacific Ocean. The surrounding area is characterized by an expanding housing development, rapidly diminishing supplies of undeveloped land, and demographic changes. CSU, Fullerton is the top employer in the city, while Orange County is home to many technology and financial services companies.

University Population

CSU Fullerton typically enrolls over 30,000 students per semester. In fall 2020, the 41,408-student population, with an average age of 23, was overwhelmingly made up of undergraduate degree seekers. Hispanic/Latinx students made up 46.2% of all students, with Asian students making up the second most populous group at 20.7%. Almost a third of all students are first-generation.

In addition to the student population, the University is home to approximately 4,000 employees.

10.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

**Requirement §201.6(c)(2):** The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

**Requirement §201.6(c)(2)(i):** [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

**Requirement §201.6(c)(2)(ii):** [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

**Requirement §201.6(c)(2)(ii)(A):** [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

**Requirement §201.6(c)(2)(ii)(A):** The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.
Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate ..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

10.3 Hazard Identification and Risk Assessment

Overview of California State University, Fullerton History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 10-1 (following).

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- Highly Likely- 76%-100% that the hazard would occur annually.
- Likely- 50%-75% that the hazard would occur annually.
- Possible- 11%-49% that the hazard would occur each annually.
- Unlikely- 0%-10% that the hazard would occur each annually.
**Communicable Disease**

**Description of the Hazard**

Communicable diseases are illnesses that occur due to infectious agents or their toxic products, and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 10-2 below.)

Descriptions of Identified Communicable Disease Hazards at CSU Fullerton

CSU Fullerton has identified two (2) communicable disease hazards that have had the greatest impact on campus – COVID-19 and Influenza. The following are brief descriptions of the communicable disease hazards at CSU Fullerton.

COVID-19 (SARS-CoV-2)

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.5

Influenza (Including sub-type H1N1/Swine Flu)

Influenza is a viral infection that attacks the respiratory system (i.e., nose, throat, and lungs). Influenza viruses travel through the air in droplets when someone with the infection coughs, sneezes or talks. Influenza is transmitted either by inhaling virus-laden droplets directly, or by coming into physical contact with an object (e.g., telephone or computer keyboard) and then transferring the virus to the eyes, nose or mouth. People with the virus are likely contagious from about a day before symptoms appear until about five days after symptoms begin.

Common signs and symptoms of the flu include: fever, aching muscles, hills and sweats, headache, dry and persistent cough, shortness of breath, tiredness and weakness, runny or stuffy nose, sore throat, and eye pain. (Vomiting and diarrhea are also influenza signs and symptoms, but these are more common in children than in adults.)

Influenza viruses are constantly changing, with new strains appearing regularly. As a result, antibodies against influenza viruses that have been encountered in the past

may not offer protection from new influenza strains, as the new strains can be very different viruses from previous strains.\(^6\)

**H1N1 Flu (Swine Flu)**

The H1N1 flu, commonly known as swine flu, is a type of influenza A virus and is one of several flu viruses strains that can cause the seasonal flu. It is primarily caused by the H1N1 strain of the flu (influenza) virus. Symptoms of the H1N1 flu are the same as those of the seasonal flu.

The H1N1 virus is a combination of viruses from pigs, birds and humans that causes disease in humans. The virus enters your body when you inhale contaminated droplets or transfer live virus from a contaminated surface to your eyes, nose or mouth. It then infects the cells that line your nose, throat and lungs.\(^7\)

**Location of the Hazard**

Communicable diseases have the potential to affect the entire CSU Fullerton planning area equally. As a result, the communicable disease hazard can be found at the CSU Fullerton campus located in Fullerton, CA (Orange County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) CSU-Fullerton are at risk of exposure to the communicable disease hazard.

**CSU Student Housing Locations and Populations**

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For CSU – Fullerton, 6% of the campus’ 39,868 students (2,392 students) lived in campus housing.

---

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard.

Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 10-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.
The Extent of CSU Fullerton Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Influenza at CSU Fullerton. Influenza would be classified at either the BSL-2 or BSL-3 containment level, depending on the strain.9

The Extent of CSU Fullerton COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.10

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 413 cases of COVID-19 at CSU Fullerton. CSU-campus-specific COVID-19 case data for CSU Fullerton can be found in the “History of the Hazard” section below.

Each CSU campus is an integral part of the surrounding community. Any event that occurs on a CSU campus has an effect on both the adjacent areas of campus and on the community-at-large – and vice-versa. Communicable disease hazard events are no exception. Most communicable disease data are maintained by at the state and at the

---

county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 10-5, 10-6, and 10-7 show campus- level and county-level COVID-19 case data for CSU Fullerton. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Since the beginning of the fall 2020 semester, the University has received the following number of reports of positive COVID-19 cases among students, employees and/or vendors/contractors who were on campus:

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including CSU - Fullerton. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of CSU campus populations contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU - Fullerton students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System's mission. This has already occurred with the current COVID-19 pandemic to some degree on the campus and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including the Fullerton campus) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

---

Table 10-7: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 10-9 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

---

Table 10-8: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG I</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

<table>

</tbody>
</table>

**Probability of Future Occurrence of the Hazard**

There have been cases of a variety of communicable disease throughout the CSU system, including COVID-19 (SARS-CoV-2), Meningitis, Measles, Influenza (Including H1N1/Swine Flu), Tuberculosis, Norovirus, Mumps, E. Coli, and Sexually Transmitted Diseases (STDs). However, there are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based
on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.

Table 10-10 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 10-9: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence. It is important to note here that a communicable disease can be rated as having a probability of future occurrence CSU-system-wide that is different from that at the individual CSU campus level.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at CSU campuses.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, the CSU – Fullerton campus had 39,868 students and additional faculty and staff.)

Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic.

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other

---

17 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx
18 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses are at risk of developing an extreme incidence of COVID-19 and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. Several CSU campuses saw refund losses surpass $10 million. (See Figure below.)

---

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table below) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources—especially if there were large numbers of infected people with immune system compromises or other underlying health problems. Table 10-13 shows the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Dam and Levee Failure**

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtopping to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the

---

nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

Orange County is home to a variety of flood control facilities and levee systems mostly along the base of the various mountains and hills throughout the county. Levees have been constructed along flood control channels providing community protection, primarily the Santa Ana River. The CSU Fullerton campus is in proximity to two relatively small dams upstream along the Fullerton Creek. The campus is not in proximity to rivers or flood control channels lined with levees.
There are a number of dam facilities along the base of the Santa Ana Mountains, Chino Hills, and the San Joaquin Hills. The larger facilities include the Prado Dam located in Riverside County on the Santa Ana River. This is a large reservoir with the potential holding capacity of 295,581-acre feet of water when full, however this lake is not a storage facility that routinely holds water instead used for flood control when needed. The CSU Fullerton campus lies outside of dam inundation zones for this facility but major transportation routes south of the campus are included.
Figure 10-4: Fullerton Inundation Map

27 California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
The Santa Ana drains the San Bernardino Mountains and parts of the San Gabriel and Santa Ana Mountains. A number of flood control systems feed into the Santa Ana River throughout the Inland Empire and northern Orange County. The length of the Santa Ana River from Prado Dam to the outlet into the ocean is a levee lined channel. The channel is located almost 3 miles southeast of the CSU Fullerton campus, is separated from the campus by additional flood control channels, and is lower in elevation than the campus. The campus is located within a levee protected zone for the Santa Ana River.

The Fullerton Creek is a drainage channel that runs alongside the northwest corner of the campus that drains a portion of the Puente Hills, Chino Hills, the Humble Reservoir, and Fullerton Reservoir. The channel feeds into the Coyote Creek Channel in La Palma. The Fullerton Creek is a rock lined flood control channel fed by additional channels near the campus. The creek is regulated by the Fullerton Dam ½ north of the campus. The campus lies within the flood inundation zone for the Fullerton Dam.

Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

Table 10-13: Orange County Dams in Proximity to CSU Fullerton

<table>

<th>Hazard Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>East Fullerton</td>
<td>Fullerton</td>
<td>1,342af</td>
<td>High Hazard</td>
</tr>
</tbody>
</table>

The CSU Fullerton campus lies within the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the CSU Fullerton campus is expected to be in the inundation area covering the campus with the exception of the southeast corner of the campus. The City of Fullerton Local Hazard Mitigation Plan provides that the inundation area is expected to spread water in areas on the campus and to the west of the campus. Additionally, there are multiple transportation corridors, utilities, and other critical infrastructure that lie within the dam inundation zones that could compromise transportation routes, service options, and areas the campus community reside or work. Based on the above factors, the planning committee ranks the extent of the hazard as **Moderate**.

**Extent - Levee Failure**

Levees are used along numerous flood control channels and other waterways including the Santa Ana River. The CSU Fullerton campus lies outside of any levee flood protected area. In the event any of these channels were flowing at elevated levels and a failure of a levee were to occur, the community surrounding the campus would likely experience flood related damages. This specific hazard could alter the ability of the campus to maintain operations but the campus is not at risk of direct impacts. Based on the above factors, the planning committee ranks the extent of the hazard as **Low**.

**History of the Hazard**

There are no records of dam or levee failures in areas that present a threat to the CSU Fullerton campus. Orange County has experienced the following dam incidents:
Table 10-14: Orange County Dam Failures

Potential Impacts of the Hazard

**Dam Failure Impacts** - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

The area downstream from the Humble Reservoir and Fullerton Reservoir includes the populated areas of Brea and northern Fullerton. These areas separate the campus and the dams in addition to border the CSU Fullerton campus. Members of the campus community who reside or are employed in these areas would be most impacted. The campus may experience the same effects from a dam inundation event that would be experienced by the broader region. This would primarily be in the form of transportation routes and other community critical infrastructure being impacted by

---

29 City of Fullerton Local Hazard Mitigation Plan, May 21, 2020
the inundation. This specific hazard would substantially alter the ability of the campus to maintain operations as damages would be extensive, the campus community in these areas would be heavily affected with the loss of life and homes, and student financial capacity to support ongoing education being diminished.

**Levee Failure Impacts** – A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

**Probability of Future Occurrence of the Hazard**

Orange County is determined to be at risk from dam and levee failure in many parts of the county. The location of the CSU Fullerton campus downstream from the Orange County / Humble Reservoir Dam demonstrates that the potential exists for future dam or levee related issues. The dam inundation zone for the Humble reservoir is stopped at the dam located in Craig Regional Park just north of the campus. There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures.
The probability of future occurrence for both dam and levee failures is **Unlikely**.

**Vulnerability to the Hazard**

Given High Priority dam monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. In addition, the campus does not lie within an inundation zone. However, in the unlikely event of a catastrophic failure, the effects of flooding from compromised dams and levees on campus would most likely be limited to indirect or secondary effects in terms of disruption to regional transportation networks and services, and the amount of time to respond to the needs of the campus community prior to inundation will be limited.

Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in the vulnerability of numerous displaced individuals and households. The lack of flood insurance will cause extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the CSU Fullerton campus will vary depending on the degree of breach or structural failure and when the failure were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals
exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $453,119,067. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU Fullerton.

**Vulnerability Assessment Conclusions**

While the occurrence of dam and levee failures have not been historically relevant near the CSU Fullerton campus, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences would be catastrophic to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.

---

**Drought**

**Description of the Hazard**

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.
Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.

- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water
supply for municipal/public use (including usage for CSU – Fullerton versus water usage for wildfire abatement or natural resource protection.

Location of the Hazard

Drought conditions have been identified in the City of Fullerton and Orange County where CSU - Fullerton is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000 – 2020, drought conditions have existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.30

Extent of the Hazard

Given the historical occurrence of severe drought impacts throughout the planning area and across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire planning equally, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. In addition, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. These effects, though not reported on the campus, remain applicable concerns for the campus over the long term.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

| Poor air quality affects health; greenhouse gas emissions increase as hydropower production decreases; West Nile Virus outbreaks rise |
| Water shortages are widespread; surface water is depleted; federal irrigation water deliveries are extremely low; junior water rights are curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor; |

**History of the Hazard**

Although campus level drought data is not available, historically, drought has been so prevalent in California that its presence is almost continuous, including Orange County which surrounds the CSU - Fullerton footprint. According to the US Drought Monitor, Time Series data, Orange County experienced numerous periods of drought between 2000-2021, including an extended period from 2012-2019.
According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.\textsuperscript{33} 34

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.\textsuperscript{35}

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% -
100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 10-6: Periods of Drought in State of California, 2001 – 2021

![Graph showing periods of drought in California from 2001 to 2021]

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state, on Orange County, which surrounds the CSU - Fullerton campus planning area:

**2012 – 2017** – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2014-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.

---

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the CSU - Fullerton campus planning area is the potential reduction in water availability for the municipal area tied to the campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - Fullerton to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of agricultural research crops and field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. However, the wildfire hazard is analyzed separately in this plan.

In reviewing the occurrences of drought for the state and Orange County, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2014-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - Fullerton, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campus. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural

underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.39

At present, drought related damage to campus buildings and infrastructure at CSU - Fullerton has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - Fullerton is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Fullerton. A reduction of electric power generation and water quality deterioration are also potential impact factors.

</table>

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that CSU - Fullerton lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Fullerton campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - Fullerton planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses.41 In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.42

---

Vulnerability of Populations

The historical and potential impacts of drought on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the CSU - Fullerton campus.

Property Vulnerability

The historical and potential impacts of drought on property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the CSU - Fullerton campus.

Natural Environment Vulnerability

Drought vulnerabilities in the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

Critical Facilities Vulnerabilities
Drought vulnerabilities for CSU - Fullerton’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought-related losses to the City of Fullerton and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

In addition to ground motion, there are several secondary hazards that can result from an earthquake including:

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at
ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU Fullerton is located in northern Orange County. In general, fault systems surround and traverse through Los Angeles and Orange Counties including the area of CSU Fullerton. Throughout the basin the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 35-40 miles northeast of the CSU Fullerton campus. In addition to the San Andreas Fault, Orange County is home to or near additional fault systems with the potential to generate strong ground shaking. The Newport-Inglewood Fault traverses south to north paralleling the Orange County coastline extending within 15 miles southeast of the CSU Fullerton campus. The Puente Hills Fault extends from the southern base of the Puente Hills to downtown Los Angeles approximately 3 miles north of the campus. The 11-mile-long Yorba Linda Fault extends from central Fullerton to the northeast into the Chino Hills 1½ miles southeast of the CSU Fullerton campus. The Whittier-Elsinore Fault extends from the eastern base of the Santa Ana Mountains and western base of the Puente Hills 4 miles to the northeast of the campus. There are numerous additional faults in the area on all sides of the campus.
Figure 10-7: Faults near CSU-Fullerton

Portions of the CSU Fullerton campus reside on areas designated to be liquefaction zones. Campus facilities that are located within the liquefaction zone include the Fullerton Arboretum, Goodwin Field, Titan Stadium, and the Children’s Center. The liquefaction zone generally follows the path of the Fullerton Creek.
Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude and intensity. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.
Portions of the CSU Fullerton campus reside on areas designated to be liquefaction zones. Campus facilities that are located within the liquefaction zone include the Fullerton Arboretum, Goodwin Field, Titan Stadium, and the Children’s Center. In addition, numerous fault systems surround and traverse the campus. Several severe and even catastrophic events have occurred in the region such as the Northridge event in 1994. Based on these factors, and the probability of future events (see below) the planning committee ranks the extent of the hazard for the campus as **Moderate to High**.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Orange County also has a long history of earthquake activity. The entire area of the Los Angeles Basin and Orange County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The January 9, 1994 Northridge Earthquake became the costliest seismic event in California history. The earthquake caused extensive damage to structures, the transportation infrastructure, utility systems, water storage, communications, and critical facilities. This level of damage due to the fault that ruptured was directly underneath a densely populated urban area. The Northridge Earthquake was found to raise the nearby mountains by as much as 70 centimeters. The earthquake was provided a federal disaster declaration (DR-1008).

The October 1, 1987 Whittier Narrows Earthquake shook a large part of southern California. The earthquake caused $358 million in damages, especially in the Alhambra, Pasadena, and Whittier areas. The earthquake resulted in extensive infrastructure damages, multiple injuries, and 8 fatalities. The earthquake was provided a federal disaster declaration (DR-799).

The February 9, 1971 Magnitude 6.5 San Fernando Earthquake struck the San Fernando Valley in Los Angeles just after 6am. The intense shaking caused the collapse of freeway overpasses, hospitals, and other infrastructure. It damaged thousands of homes and businesses, a reservoir, and critical infrastructure. 65 people were killed and 2,000 more were injured. The shaking was felt for 300 miles including...
in Las Vegas, Nevada. The earthquake was provided a federal disaster declaration (DR-299).

The March 10, 1933 Long Beach Earthquake registered at a Magnitude 6.4 occurred along the Newport-Inglewood Fault. The earthquake resulted in over $50 million in damages, 500 injuries, and 120 fatalities. Unreinforced masonry structures were the source of most of the casualties. 70 schools were destroyed and 120 were damaged. This earthquake promoted statewide standards in building design and construction for schools and other structures to better withstand seismic events.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils to the east and west of the campus presents a potential for liquefaction creating greater ground instability during seismic events. The northern sections of the campus is located on a liquefaction zone A major earthquake in the Fullerton area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Fullerton could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Fullerton could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Orange and Los Angeles Counties region limiting immediate assistance that the campus may normally expect.

Local impacts to CSU Fullerton campus caused by an earthquake could include:

- Damage and secondary fires to industrial buildings to the south of the campus
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway system
- Damages to railyard, rail lines, and rail cars 1 mile to south of campus
- Structural damage to bridges
- Damages to oil fields west of campus in East Coyote Hills
- Potential isolation of campus from community
• Potential isolation among on-campus residents
• Damages to homes and apartment complexes surrounding the campus and in broader community
• Structural damage to Fullerton and Humble Reservoirs
• Damage to flood control and drainage systems
• Structural damage to campus academic and support buildings
• Structural damages to parking structures
• Structural damage and reduction of capacity of trigeneration power plant
• Damages to emergency generator system
• Structural damage to residence halls resulting in displaced student populations
• Structural damage to nearby residences
• Community members arriving on campus for refuge from damaged homes
• Damaged university communications, computer systems, and networks
• Considerable stress and fear among community
• Closure or reduction of service to campus operations
• Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Orange County fault systems surrounding Fullerton is included in the following table.

Based on the earthquake shaking potential in the Orange County region, the proximity to the above listed fault systems, the probability of seismic ground shaking generating damage is considered **Possible**.

**Vulnerability to the Hazard**

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of Fullerton places the campus in a busy commercial and industrial areas that is heavily populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus. Portions of the northern side of the campus are designated as liquefaction zones and may be impacted by the Fullerton and Humble Reservoirs if full.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

The known fault systems generating the threat to Fullerton generally surround the city and some cross into the city including near the CSU Fullerton campus. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous
displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the CSU Fullerton campus will vary depending on when the earthquake were to strike. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with sheltering and care of those unable or unwilling to return to their homes. Damages to the homes of the members of the campus community may place greater demands on campus resources and capabilities in the short-term period following a seismic event.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. As the CSU Fullerton campus is downstream from dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical
damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $453,119,067.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater Orange County region and the CSU Fullerton campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU Fullerton campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding Fullerton, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Orange County region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places
of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

Vulnerabilities will be seen in the physical infrastructure on the campus and the human population of the campus community. Campus infrastructure is vulnerable to severe shaking particularly in areas where the ground is loose or susceptible to liquefaction. Specifically older buildings, masonry constructed buildings, and other structures susceptible to shaking related damage are the most vulnerable. Communication systems, computer networks, and other electronic systems may be vulnerable when overwhelmed by increased demand during emergencies or by shaking related damages. The people of the campus community are vulnerable to effects of intense shaking in the form of injuries from falling debris, exposure to secondary floods or fires, loss of employment, extreme disaster induced stress, and loss of access to critical services or social contacts.

The campus population is additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

**Identified Data Limitations**

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.
Erosion

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.”49 Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While coastal erosion can happen in any storm, it is more likely during El Nino events, which occur every 5-7 years.

Other incidents of erosion, such as around building foundations, can occur in any locations with conducive soil structure and a source of movement, such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. For the purpose of this analysis, the risk is located consistently across those areas of the campus with erosion-prone characteristics. In the future, the campus leadership may fully investigate to what extent specific sites of erosion activity are observably in process, given that erosion has caused past damage on campus.

In agricultural areas, the erosion of soil degrades the quality of the soil, which can lead to reduced crop yields.50 At the Fullerton Arboretum Learning Farm, soil erosion can create significant concerns for agriculture and research. Eroded test plots can negatively impact experiments and tests, resulting in a loss of knowledge and data.

Extent of the Hazard

Erosion is occurring on the Pacific coastline west of CSU Fullerton. While there is no published scale of severity or extent for this geologic hazard on the CSU Fullerton campus, erosion is likely to occur if conditions are favorable. Given that such

conditions exist and have resulted in damages to campus infrastructure, the planning committee ranks the extent of the hazard as **Moderate**.

**History of the Hazard**

Erosion resulting from heavy rainstorms in 2017 has contributed to structural damage on campus. Heavy precipitation also poses a risk of erosion to outdoor landscapes.

**Potential Impacts of the Hazard**

Coastal erosion can result in severe impacts to infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

**Probability of Future Occurrence of the Hazard**

Erosion is an on-going and dynamic process that occurs regularly. As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. As a result, and in consideration of the potential extent of erosion, the probability of future occurrence is high.

**Vulnerability to the Hazard**

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Fullerton infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion.

In the wider Los Angeles community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

**Vulnerability Assessment Conclusions**

While the ability to predict future erosion on the CSU Fullerton campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left
unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

Description of the Hazard

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.51

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.52 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feels” hotter. The combination of temperature and humidity is known as the heat index.53

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.54 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.55

Location of the Hazard

Extreme heat events are a non-spatial hazard and may occur at the Cal State Fullerton campus.

---

53 Ibid.

Extent of the Hazard

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the high 70s to high 80s in the City of Fullerton. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at the Fullerton Municipal Airport was 116°F on July 6, 2018. This was part of a large-scale heat event that affected much of the western United States. In California, combined conditions of heat and dryness fueled spreading wildfires, leading to deaths, evacuations, and power outages across large sections of the state. Given 9 extreme heat events since 2007, along with the history of event impacts, along with increased risk of wildfires, the planning committee ranks the extent of the hazard as Moderate.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100°F – 104°F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105°F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 10-12 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

As the heat index rises, so does the potential danger to people and animals. Table 10-23 (following) shows the health hazards associated with extreme heat.

Table 10-22: Health Risks Associated with Heat Index

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been nine excessive heat events in Orange County since 2007. A few of these events have been grouped into two- or three-day heat waves.

**September 2, 2007:** A combination of high temperatures and high humidity produced an extreme heat event across most of Southern California. Heat index values during this heat wave ranged from 105° to 112° F. There were eight deaths attributable to this excessive heat event.

**September 1, 2017:** This heat event began in late August and extended into early September, affecting most of the western United States. Many metro areas broke daily, monthly, and even all-time heat records.

**October 23-25, 2017:** A second heat wave followed approximately two months later, primarily in Southern California. The City of Fullerton reached a temperature of 107° F.

**July 6, 2018:** As mentioned above, this heat event was part of a larger heat wave that affected much of California. As part of this heat event, more than 30,000 customers of the Los Angeles Department of Water and Power experienced power outages and Flex Alerts were issued by state authorities.

**September 13, 2019:** After high temperatures in both July and August, temperatures again climbed to 15 to 20 degrees above normal (or higher) in areas of Southern California.

**October 21-22, 2019:** This heat event, occurring much later than usual, also fueled heightened concerned about wildfires.

**Potential Impacts of the Hazard**

Cal State Fullerton may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

**Probability of Future Occurrence of the Hazard**

There have been multiple excessive heat events over the last decade that have impacted the City of Fullerton. Therefore, using the scale provided, it is highly likely that the hazard will occur annually.
Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.58 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Several cooling centers are open throughout Orange County during extremely hot days, however, the campus’s limited emergency notification and communication system may make it difficult for Cal State Fullerton to spread information about cooling centers to more vulnerable campus populations, such as students with access or functional needs and international students who may have a language barrier.

The risk of power shut-offs affecting air conditioning is not a concern for on-campus facilities because Cal State Fullerton has a system of solar panels and also has its own campus substation. The campus is able to generate approximately 13% of its energy from a clean, renewable energy source.59

Extreme heat is a hazard that the campus may experience with regularity, and there are a few improvements that could help Cal State Fullerton handle the risks and vulnerabilities.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at Call State Fullerton is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three

degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.⁶⁰

**Identified Data Limitations**

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

---

**Flood**

**Description of the Hazard**

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result

---

from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Floods can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.
Atmospheric River

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
The science behind atmospheric rivers

An atmospheric river (AR) is a flowing column of condensed water vapor in the atmosphere responsible for producing significant levels of rain and snow, especially in the Western United States. When ARs move inland and sweep over the mountains, the water vapor rises and cools to create heavy precipitation. Though many ARs are weak systems that simply provide beneficial rain or snow, some of the larger, more powerful ARs can create extreme rainfall and floods capable of disrupting travel, inducing mudslides and causing catastrophic damage to life and property. Visit www.research.noaa.gov to learn more.

Location of the Hazard

Fullerton lies at the base of the Coyote Hills in Orange County. Along the northern edges of Orange County are low rising hills that are a part of the Transverse Ranges. These include the Puente and Chino Hills which provide a potential for developing water run-off during heavy precipitation events. There are a number of flood retention basins and flood control channels along the base of these hills to protect these Orange County communities including Fullerton. The area surrounding the campus is a developed suburban environment predominately consisting of residential and commercial land uses.

The CSU Fullerton campus is located 2-3 miles north of the Santa Ana River that flows through Anaheim. The Santa Ana River watershed receives the majority of its water from snowfall from the Santa Ana, San Bernardino, and San Gabriel Mountains. The Santa Ana River does not contribute to a direct flood hazard to the campus but may compromise access routes to the campus. The Fullerton Creek extends along the northwest corner of the campus. Fullerton Creek when filled with water drains from the Fullerton Reservoir and Humble Reservoir located ½ mile and 3 miles respectively to the north of the campus. The majority of the CSU Fullerton campus sits within a Special Flood Hazard Area (SFHA) Zone X: Area of Minimal Flood Risk designation on the Flood Insurance Rate Map. Extending down State College Blvd, portions of the Nutwood Parking Structure, parking lot C West, and parking lot A reside in a Zone X: 0.2% of Annual Chance of Flood Hazard.

Extent of the Hazard
The CSU Fullerton campus is located predominately in a designated Zone X: Area of Minimal Flood Risk. Portions of the western edges of the campus are located within a
Zone X: 0.2% Annual Chance Flood Hazard. The neighborhoods opposite of the State Route 57 Freeway are designated as Zone X: 0.2% Annual Chance Flood Hazard. Based on these factors along with no history of flooding on campus other than occasional small-scale ponding and isolated street flooding, the planning committee ranks the extent of the hazard on campus as **Low**.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

**Table 10-23: Flood Zone Designations and Descriptions**

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised maps in place on Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone</td>
<td>Percentage Chance of Flooding</td>
<td>Description</td>

<tr>
<td>Zone AO</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding, where shallow flooding average depths are between one and three feet.</td>
</tr>
<tr>
<td>Zone X (shaded)</td>
<td>0.2%</td>
<td>Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.</td>
</tr>
<tr>
<td>Zone X (unshaded)</td>
<td>Undetermined</td>
<td>Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No Base Flood Elevation or depths are shown within this zone.</td>
</tr>
</tbody>
</table>

**History of the Hazard**

Flooding in Fullerton and the broader Orange and Los Angeles County regions have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the CSU Fullerton campus. No flood events have been reported specifically for the
campus, though heavy rainfall events will sometimes produce small-scale flooding and/or ponding.

62 City of Fullerton Local Hazard Mitigation Plan, May 21, 2020
Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities, including on campus power generation
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Threat, inundation, or damage to on campus childcare facilities and occupants
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

Orange County is determined have considerable portions of the county to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common in the Fullerton area with winter storms that are saturated with subtropical moisture. The area surrounding the CSU Fullerton campus does not generally promote conditions for flood waters to accumulate. The campus is designated as Zone
X (Area of Minimal Flood Hazard). However, bordering on both the east side and west side of the campus are areas designated as Zone X (0.2% of Annual Chance of Flood Hazard). There are specific buildings and areas of the campus that have a greater risk for isolated flooding. However, the area is subject to isolated urban or street flood events providing a demonstration of potential flood activity.

The probability of future occurrence for flooding is **Unlikely**.

**Vulnerability to the Hazard**

The CSU Fullerton campus is subject to the effects of limited and isolated flooding resulting primarily from localized flooding and ponding from excessive precipitation and isolated strong storms. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of Fresno due to overflow or damage to flood control systems such as the Fullerton Creek System. The flood control channels and drainage systems that surround the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the CSU Fullerton campus will vary depending on when the flood were to occur and on the location of any people or assets within any low lying areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community may become trapped on campus depending on the level of flooding occurring on surface streets. However, in region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

CSU Fullerton is in proximity to residential neighborhoods and commercial areas. When these areas are inundated with flood water, the potential for release of contaminants, hazardous materials, biological contaminants, and other chemicals presents possible exposures to individuals from the campus community. Any flood waters left standing in the area would pose a significant vulnerability to the campus community remaining on campus in potential health and safety effects.

Some campus buildings and infrastructure in low lying areas might be vulnerable to low probability, large-scale flooding if it reaches the university. Campus utilities, including the on-campus power plant, and communication capabilities could be impacted by flood waters rendering them disabled. A rare flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls in low lying areas may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. In such areas, flood waters may result in damage to campus equipment, communication systems, protected
documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $453,119,067. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. The proximity to the Fullerton Creek and Santa Ana River further presents an additional flood risk factor to the campus.

Vulnerabilities to flood will be seen in the physical infrastructure on the campus and the human population of the campus community. Campus infrastructure is vulnerable to water inundation particularly in areas where large water sources are in proximity to the campus allowing greater volumes of water to arrive. Specifically low-lying buildings, temporary constructed buildings, and structures with generators, HVAC, critical control systems, or other key components at or below ground level are the most vulnerable. Communication systems, computer networks, and other electronic systems may be vulnerable when overwhelmed by increased demand during emergencies or by water inundation on electronic equipment. The people of the campus community are vulnerable to effects of flooding in the form of injuries from flood waters, exposure to secondary fires, loss of employment, introduction of disease, extreme disaster induced stress, and loss of access to critical services or social contacts.

The potential for flooding generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects could be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for rare, widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.
Identified Data Limitations

Lack of comprehensive historic flooding occurrences, missing campus structural replacement costs, and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.

**Hazardous Materials**

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident**

A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident**

A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident**

A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

---

Hazardous materials can also be classified according to worker safety and health.\(^6^4\) Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards** (fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards** (carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natecs)**

During the past two decades, increasing attention has been given to hazardous materials releases resulting from *Natechs* or a natural disaster event that triggers a technological hazard event. As pointed out by Lindell and Perry (1996), Young, Balluz, and Malilay (2004), and Steinburg, Sengul, and Cruz (2008), natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities\(^6^5\)
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters\(^6^5\)
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. Please refer to Annex ? for the map identifying the types and locations of hazardous materials and infrastructure on or near the CSU – Fullerton campus. The planning committee indicates that chemicals are located in the science lab, but otherwise no known hazardous materials are present on campus. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city of Fullerton and Orange County, and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached

which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

However, for the CSU – Fullerton planning committee, although no hazmat events have taken place on campus, and hazardous materials are limited to chemicals in the science building, gas pipelines and hazardous waste sites are located very close to the campus, as well as chemical facilities and a rail line located about 1.5 miles from the campus. Based on these factors along with the types and levels of hazardous materials in the larger community, it is prudent to rank the extent of the hazard for the CSU – Fullerton campus as Low to Moderate, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.66

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.67

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

For more details on specific hazmat events, please refer to the local, county and/or multi-jurisdictional hazard mitigation plans where CSU campuses are located at: https://www.caloes.ca.gov/cal-oes-divisions/hazard-mitigation/hazard-mitigation-planning/local-hazard-mitigation-program

According to the campus planning committee, no hazmat events have taken place on the CSU – Fullerton campus.

______________________________

Potential Impact of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – Fullerton campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health.\textsuperscript{68} Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.\textsuperscript{69}

**Potential Impact of the Hazard (Natecs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms

experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Fullerton) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.70

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the CSU – Fullerton campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low to Moderate - the risk on campus is limited to chemicals in the science lab, and the campus has not experienced a hazmat event. However, nearby hazardous waste sites and gas pipelines increase vulnerability. That said, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the CSU – Fullerton campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: chemicals are present in the science lab, and gas pipelines and hazardous waste sites are very close to the campus footprint. Gases and chemicals or hazardous waste, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Fullerton leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Fullerton) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Orange County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Fullerton campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground...
Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – Fullerton planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow.\textsuperscript{72} These landslides may impact lives and properties within the deposition zone and can result in downstream flooding. Post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 10-16. Based on the Figure below, the Fullerton campus is located somewhat adjacent to, but outside of landslide susceptibility zones.

Figure 10-13: Deep-Seated Landslide Susceptibility Surrounding CS-Fullerton

Extent of the Hazard

In Orange County, landslides are more likely to occur in the steep slopes outside of the metropolitan areas and along the coastline. The San Gabriel mountains, both steep and erosive, contain steeply walled canyons above areas with high population density. When heavy rain occurs, there is significant potential for floods and landslides throughout the County and indirect impacts may cover a larger geographic extent than that of direct impacts. Based on the campus’ location and only 1 historical occurrence of landslide in the City of Fullerton, the planning committee ranks the extent of the hazard on campus as **Low**.

History of the Hazard

NOAA recorded eight debris flow events in Orange County from 2003 to 2019. These occurred in the Santa Ana mountains south of Fullerton. FEMA has declared thirteen

---

major disasters involving landslides, mudslides, mudflows, and debris flows since 1978. The only recorded landslide in the City of Fullerton was in January 2005 when a five-day rainstorm destabilized an embankment at the 2000 block of North Euclid Avenue and the 1800 block of Harbord Boulevard. There were no injuries, deaths, or significant property damage, but the roads were closed for several days. The campus has no record of landslide occurrence.

 Potential Impacts of the Hazard

CSU Fullerton may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

 Probability of Future Occurrence of the Hazard

Slope failures are also often triggered by other natural hazards, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred occasionally around Fullerton and therefore are likely to occasionally occur in the future. Most of the city is on flat terrain, so the likelihood of a landslide in the city is low. The likelihood of occurrence on campus is ranked as Unlikely.

Vulnerability to the Hazard

Any population proximal to a landslide when it occurs is vulnerable to its impacts. There are three pump stations in Fullerton that are in potential earthquake-induced landslide areas, as shown in Figure 10-17. The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical

distress. The campus’ vulnerability is limited to the secondary effects of landslide to transportation routes.

Figure 10-14: Landslide Hazards

![Landslide Hazards Map]

**Estimate of Potential Losses**

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Fullerton.

**Vulnerability Assessment Conclusions**

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**
The ability to predict future landslides at the CSU Fullerton campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.\textsuperscript{13}

\textbf{Power Outage}

\textbf{Description of the Hazard}

CSU Fullerton is home to one of Southern California Edison’s registered commercial power plants in the city known as, CSUF Trigeneration. There are seven power substations: the Norweld, Gilbert, Sunnyhills, Basta, Fullerton, Paper, and Titans Substations. Although these are not all the resources for power for the City of Fullerton, they offer external connections to generate power with some redundancies against power outages, in the events that an individual power line is damaged. Damage to a substation may result in a much greater loss of energy.

Most aspects of modern life, and almost all aspects of suburban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An Interruption in the supply or distribution of these commodities can leave highly populated areas, like Fullerton, with basic services, such as electricity or sanitation with an inability to manage. These interruptions can be cascading effects from other hazards, such as the result of major windstorm, or they can be caused by intentional disruption of transmission lines. Fullerton sits at the junction of State Route 57, 91 and Interstate 5, where the city is a major gateway from the Inland Empire to Orange County.

In the event of a power outage at CSU Fullerton, some possibilities from a power outage event can disrupt day-to-day operations of the campus, like in-person classes, potentially impede or limit digital, limit telephonic or radio communications, create traffic jams around the campus’s thoroughfares and boulevards surrounding the campus. Additionally, impacts can occur to the surrounding campus community by forcing temporary closures of local restaurants. Additionally, thousands of Fullerton State student residents in on-campus housing would also be affected by a power outage on campus and students residing in off campus housing close to the university.

Additionally, a severe outage to Orange County or the City of Fullerton would also directly affect the campus and the community creating social, economic, and potential health and safety impacts. To avoid an exacerbation of the hazards

An electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of \textbf{intentional} disruptions:

- Planned: Some disruptions are intentional and can be scheduled based maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities, and the California Independent System Operator (CAISO), which is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities. CAISO is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of “stage alerts” to the media based on system conditions.

The alerts are as follows:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
Stage 3 - reserve margin falls below 1.5 percent. Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard
CSU Fullerton did not report a history of power outages affecting the campus.
The City of Fullerton has experienced losses over time due to power losses as secondary events due to other events, like wildfires, thunderstorms, floods, etc. The following are events that experienced power outages as a cascading event.

- In February 1998, all of Southern California was impacted by heavy rains when 2 to 5 inches fell across the region. Many roads and bridges were washed away, or destroyed, and widespread power outages occurred.
- In October 1998, a thunderstorm sent destructive winds through Orange County. Trees everywhere were uprooted and blown onto vehicles and buildings. A power outage affected more than 18,000 utility customers across the communities of Los Alamitos, Rossmore, Cypress, Tustin, Santa Ana, and Garden Grove.

Potential Impacts of the Hazard
Instructors, campus residents, staff and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations if a significant event occurs. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

Climate Change and Energy Shortage
Climate change is expected to bring more frequent and intense natural disasters. Over the years, what was once a disaster uncharacteristic to landscape is now occurring outside of historical areas. These changes have created a variability at a rate that
makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

Probability of Future Occurrence of the Hazard

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. Fullerton and Los Angeles County experience such outages. As such, the probability ranking for the Fullerton area is Likely; although the campus has recorded fewer events than the surrounding area, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

Vulnerability to the Hazard

Based on the data available, and in consideration of the increasing effects of climate change, the probability future occurrences prompting intentional outages and creating unintentional power outages the hazard is high for the county in different areas but not specifically influencing the campus. Nonetheless, it would serve the campus to ensure to be able to mitigate and cope with an interruption to electrical power.

In an effort to maintain resilience on the CSU Fullerton campus, Upgraded electrical on campus. Mitigation efforts have been made through the acquisition and implementation of portable and fixed generators to supply power during power
outages. The campus has twenty-one fixed and portable generators throughout the campus and ready for deployment. These generators can be useful in the event that an evacuation must occur to ensure the safety of students, faculty, and staff. Additionally, the university has solar panels on campus that generates 15% of the electricity on campus. The solar panels add a reliable system of energy that will support the campus immediate needs until generators can be activated and engaged.

Estimate of Potential Losses

The data provided by CSU Fullerton does not report any value for potential losses due to power outage.

Vulnerability Assessment Conclusions

The vulnerability assessment concludes a power outage would impacts various ways, mainly due to other initial disaster events. Power outages can impact health, and certain populations may be more at risk. An unexpected power outage can create an interruption in operations on campus causing classes or event cancellation. During an expected power shutoff event, modifications may have to take place for the duration of the outage, like transitioning to a cyber or remote classroom environment, virtual conferences or postponement of classes or events. Additionally, staff may have to continue their everyday operations from a remote location like their own residences, alternative office space or a neighboring campus.

A loss of power outage can lead to potential hazards to students, faculty, and staff at CSU Fullerton. Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary functions to navigate through the campus with ease, maintain a safe campus environment and visibility during nighttime hours. The vulnerable population, like students with physical disabilities may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors and locks and lights may impede on a student with a disability’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept continuing operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

Data referencing the impacts of a power outage were not reported by the university.
Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU Fullerton or Orange County is located within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While CSU Fullerton does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.
History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California.\textsuperscript{11} The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.\textsuperscript{12}

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Fullerton is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Fullerton.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability to the Hazard
Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Fullerton, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

**Estimate of Potential Losses**

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

**Vulnerability Assessment Conclusions**

CSU Fullerton is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

**Identified Data Limitations**

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

---

**Wildfire**

**Description of the Hazard**

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression
actions to contain.77 These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

77 State of California Hazard Mitigation Plan, September 2018
A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

Location of the Hazard

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. CSU Fullerton and the City of Fullerton are located in northern Orange County. This region is dominated by urban and suburban communities with limited direct exposures to wildland fire. CSU Fullerton has extensive residential neighborhoods to the north, south, and west of the campus. Large industrial land uses are located to the east of the campus and beyond the neighboring residential areas.

The CSU Fullerton campus is located in the eastern side of Fullerton bordering the City of Placentia. The campus is ½ mile from the eastern base of the Coyote Hills where there is a mix of residential neighborhoods and hillsides with moderate vegetative fuels. The campus is also 6-7 miles from the Puente and Chino Hills with extensive areas of fire hazard potential. The campus is not located next to areas with a fire hazard potential making direct impacts by fire on the campus unlikely.

However, the CSU Fullerton campus is surrounded by mountains and extensive areas of fire hazards further away. Surrounding the Los Angeles Basin and Orange County are large mountain ranges including the San Gabriel, San Bernardino, and Santa Ana Mountains. These mountain ranges host three national forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the basin in the right wind conditions. The geography of the Los Angeles Basin and San Gabriel, San Bernardino, and Orange County valleys creates a topography that captures air pollutants including smoke within surrounding mountains and the development of inversion layers. The CSU Fullerton campus is located in a region in which wildfire smoke can saturate the air around the campus.
## Extent of the Hazard

The area immediately surrounding the CSU Fullerton campus is not in direct proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat and the Fullerton campus has experienced multiple days of poor air quality due to fires burning in the mountains. Based on the (above) factors, the planning committee ranks the extent of the hazard as **Moderate**.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and

---

equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 10-26: National Fire Danger Rating System\(^\text{79}\)

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
<td></td>
</tr>
<tr>
<td>CLASS 4: Very High Danger (VH)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Fires start very easily and spread at a very fast rate</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CLASS 5: Extreme (E)</th>
<th>Fire situation is explosive and can result in extensive property damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Red</td>
<td>Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</td>
</tr>
</tbody>
</table>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke.

The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Orange County also has a long history of wildfire activity primarily in the foothills and mountains of the Santa Ana Mountains, the Chino Hills, and the San Joaquin Hills. Wildfires occurring in Orange County have resulted in hundreds of thousands of acres burned and millions of dollars in damages.

The area immediately surrounding the CSU Fullerton campus is not in direct proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Fullerton campus has experienced multiple days of poor air quality due to fires burning in southern California mountains. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Orange County. CSU Fullerton personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

Potential Impacts of the Hazard

The location of the CSU Fullerton campus surrounded by areas of urban development removed from areas with a fire hazard places a minimal direct threat from wildfire to the campus. The greater potential impacts to wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Threat or damage to on campus child care facilities
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities, on campus power generation
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts on vulnerable populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects

---

82 City of Fullerton Local Hazard Mitigation Plan, May 21, 2020
Similar health impacts to pets
  - Air conditioning systems overwhelmed
  - Greater demands on air filtration systems
  - Greater demands on healthcare systems
  - Reduced outdoor work productivity
  - Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Orange County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the minimal wildfire threat potential in the area surrounding the CSU Fullerton campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered **Unlikely**.

Based on the wildfire threat potential in the area surrounding Southern California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered **Possible**.

Vulnerability to the Hazard

The CSU Fullerton campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban/suburban area of Fullerton. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other areas. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have
improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

Some areas of particular vulnerability on the campus includes:

- Students and staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC or do not have HVAC will cause limitations in filtering of air during smoke filled days.
- Power outages or brownouts during days with high levels of smoke will limit shelter in place options during heat events in summer.
- Santa Ana wind events may push large volumes of smoke into Orange County.

The greater concerns regarding vulnerabilities to wildfire on CSU Fullerton are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the air around Orange County even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Fullerton students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU Fullerton campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and...
windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $453,119,067. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher. However, the location of the campus in an urban/suburban setting removed from hazard prone areas makes wildfire related damages unlikely.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Orange County, however, wildfire incidents do not typically pose a direct risk to the CSU Fullerton campus. The location of the CSU Fullerton campus surrounded by densely developed residential, commercial, and industrial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The students, faculty, and staff of CSU Fullerton who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the campus. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local
economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.

Additionally, the topography of Southern California surrounded by mountains allows for smoke filled air to linger in the valleys of the Los Angeles Basin with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains generating tremendous quantities of smoke present tremendous health related vulnerabilities to members of the campus community. The campus community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

**Identified Data Limitations**

Lack of comprehensive historic fire occurrences, missing campus structural replacement costs, and complete inventory of building construction features or mitigation efforts to lessen the impact due to fire activity.

**Severe Weather (Wind, Tornado, Hail, Lightning)**

**Description of the Hazard**

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

---

Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU Fullerton.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including

---

88 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
“atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.90

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU Fullerton), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.91

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.92 The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.93 These storms affect (in varying degrees) all CSU campuses, including CSU Fullerton.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.94 Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.95 Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.96 **Severe thunderstorms** are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements:

---

90 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
91 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\(^\text{97} \text{ 98}\)

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.\(^\text{99}\)

- **Wind storm**: marked by high wind with little or no precipitation.\(^\text{100}\)

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\(^\text{101}\)

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.\(^\text{102}\)

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\(^\text{103}\)

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\(^\text{104}\)

\(^\text{97}\) Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
\(^\text{98}\) Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

Wind Hazards

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\(^{105}\) Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” \(^{106}\)

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU Fullerton).

High Winds, Strong Winds, and Thunderstorm Winds

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\(^{107}\)

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\(^{108}\)

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\(^{109}\)

Please note: Straight-line wind is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\(^{110}\) However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

Tornadoes

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\(^{111}\) This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\(^{112}\) On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\(^{113}\)

Santa Ana Winds. A type of wind hazard that is peculiar to Southern California is called a Santa Ana Wind. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\(^{114}\) They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation.

\(^{113}\) Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions
They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{115} (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

Figure 10-17: What Drives a Santa Ana Wind?\textsuperscript{116}

\textbf{Diablo Winds.} The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface

\textsuperscript{116} Retrieved on 07.14.2021 from https://twitter.com/nwslosangeles/status/933049473034579968
A pressure gradient that forms in response to an inverted pressure trough that develops over California.\textsuperscript{117}

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.\textsuperscript{118} 119 120

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.\textsuperscript{121} It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.\textsuperscript{122}

\textsuperscript{117} Retrieved on 07.13.2021 from https://www.fireweather.org/diablo-winds
\textsuperscript{121} Retrieved on 07.14.2021 from https://www.nssl.noaa.gov/education/svrwx101/hail/
**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\(^1\)\(^2\)\(^3\)

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\(^1\)\(^2\)\(^4\) Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the CSU Fullerton campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all CSU Fullerton campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU Fullerton reflect those of the surrounding community and County. As a result, all assets and people at CSU Fullerton are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Fullerton area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

</table>
Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{128}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the **date** that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 10-30: Fujita Tornado Scale (Pre-February 2007)\(^{129}\)

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms.\textsuperscript{133} \textsuperscript{134} That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light, medium, or heavy* according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\textsuperscript{136}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{136}

- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{137} or

- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder). \textsuperscript{138} \textsuperscript{139}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

\textsuperscript{132} Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
\textsuperscript{134} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
History of the Hazard

Severe weather hazards have been an annual occurrence in Orange County and on the CSU Fullerton campus. Historical data for these hazards are presented below.

Historical Storm Data Collection: NCEI Storm Events Database

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type. For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events. To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Orange County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind**: at least 176 events, or approximately 6.95 events per year

---

144 National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType%28Z%29=HighWind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=ORANGE%3A59&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA
- **Strong Wind**: at least 15 events, or 0.59 events per year\(^{145}\)
- **Thunderstorm Wind**: at least 34 events, or approximately 1.34 events per year\(^{146}\)
- **All Wind Hazard events** (excluding Tornadoes): at least 219 events, or approximately ### events per year.\(^{147}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Orange County, there have been at least 219 wind hazard events since 1996, excluding tornadoes.\(^{148}\) That translates to an approximate average historical frequency of occurrence of **8.64** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 225 events) and simultaneous Database searches of all severe weather hazard events (i.e., 219 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Orange County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{149}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 219 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

---

Historical Wind Hazard Losses for Orange County since 1996

According to the NCEI Storm Events Database, the wind hazard events that Orange County has experienced since 1996 have been costly. There has been 1 death and 0 injuries, and property and crop damage estimates have totaled approximately $2,417,000 and $21,000, respectively.\(^{150}\)

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 7 reported events of tornadoes in Orange County, which translates to approximately 0.28 tornado events per year.\(^{151}\)

Four (4) of the tornado reports in Orange County since 1996 have been of tornadoes with a severity rating of F0/EF0. The remaining three (3) tornadoes reported have each had a severity rating of F1/EF1; that translates to approximately 0.12 events of F1/EF1 tornadoes have occurred per year in Orange County.\(^{152}\)

Historical Tornado Hazard Losses for Orange County since 1996

According to the NCEI Storm Events Database, the tornado hazard events that Orange County has experienced since 1996 have been costly. While there have been no reported deaths, injuries, or crop losses, property damage estimates have totaled approximately $600,000.\(^{153}\)

\(^{153}\) National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=ORANGE%3A59&hailfilter=0.00&tornfilter=0.00&windfilter=0.00&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA
**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 11 reported events of hail in Orange County, which translates to approximately 0.43 hail events per year.\(^{154}\) (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 12 reports of hail since 1996. However, one (1) entry is for a 1998 hail event in San Diego County. While Orange County is adjacent to San Diego County, there is no indication in the event details that hail ever reached Orange County during this event. The origin of this reporting discrepancy is unknown at this time.)

**Historical Hail Hazard Losses for Orange County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Orange County has experienced since 1996 have been costly. There have been 1 death and 0 injuries, property damage estimates have totaled approximately $80,600; no crop damage estimates have been reported.\(^{155}\) (Note: The San Diego County hail event that was included erroneously in the search results for hail events in Orange County accounted for all hail injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been four (4) reported events of lightning in Orange County, which translates to approximately 0.16 lightning events per year.\(^{156}\)

**Historical Lightning Hazard Losses for Orange County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Orange County has experienced since 1996 have been costly. While there have been no deaths,
injuries, or crop damage from lightning reported, property damage estimates have
totaled approximately $62,000.\textsuperscript{157}

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

Information obtained from the NCEI Storm Events Database indicates that there have
been 241 occurrences of the severe weather hazard in Orange County. This translates to
9.51 severe weather hazard occurrences per year.\textsuperscript{158}

Please note: Differences between the sums of individual component severe weather
hazard event Database searches (i.e., 248 events) and simultaneous Database searches of
all severe weather hazard events (i.e., 241 events) may be due to the following factors: (1)
multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or
"Hail/Tornado;”) and/or (2) severe weather hazard events such as “Thunderstorm Wind”
or “Hail” that are reported for Orange County have actually taken place hundreds of miles
away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{159} When
such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e.,
241 events) is used to determine the historical frequency of occurrence for the severe
weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Orange County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Orange
County has experienced since 1996 have been costly. There have been 2 deaths and 0
injuries, and property and crop damage estimates have totaled approximately $3,160,000
and $21,000, respectively.\textsuperscript{160} It is important to note that for all Orange County severe
weather hazard events recorded on the Storm Events Database, half of all deaths, all crop
damage estimates, and approximately 76.5% of all property damage estimates, have
been caused by wind hazard events alone.

Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April.\textsuperscript{161} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textbf{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6 days accounting for 90\% of all occurrences. The remaining 10\% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{162 163}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Diablo Winds

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^{166}\)

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.167

Figure 10-19: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)168

Sundowner Winds

Strong sundowner wind events occur approximately 2-3 times per year. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.169

Historical Frequency of All Severe Weather Hazards

Table below shows the average historical frequency of severe weather hazard events for Orange County since 1996.

Potential Impacts of the Hazard

All assets and people within CSU Fullerton campus areas are at risk from the effects of severe weather.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU Fullerton campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.
According to the 2021 County of Orange and Orange County Fire Authority Local Hazard Mitigation Plan (LHMP), wind hazards (including tornadoes) are considered to be of low significance, and therefore to have a minimal potential impact on the County and (by extension) the CSU Fullerton campus.170

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

According to the 2021 County of Orange and Orange County Fire Authority Local Hazard Mitigation Plan (LHMP), hail hazards are not addressed at all in the Plan; they are considered to be of low significance, and therefore to have a minimal potential impact on the County and (by extension) the CSU Fullerton campus.171

**Lightning**

Lightning strikes the United States about 20-25 million times a year.172 Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.173 Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.174 (Commercial claim payouts for lightning losses for the U.S. were not available.)

According to the 2021 County of Orange and Orange County Fire Authority Local Hazard Mitigation Plan (LHMP), lightning hazards are not addressed at all in the Plan; they are considered to be of low significance, and therefore to have a minimal potential impact on the County and (by extension) the CSU Fullerton campus.175

---

Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The 2021 County of Orange and Orange County Fire Authority Local Hazard Mitigation Plan (LHMP) states that there is a 10-100% probability that wind hazards profiled above for Orange County will occur annually in the future, and but does address the probabilities of annual occurrence for tornadoes, hail, or lightning. However, according to the NCEI Storm Events Database, wind hazards have occurred in Orange County more than once per year. Also, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Fullerton campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU Fullerton campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2021 County of Orange and Orange County Fire Authority Local Hazard Mitigation Plan (LHMP) and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU Fullerton campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU Fullerton is HIGHLY LIKELY. See Table below for probabilities of future occurrence for component severe weather hazards for the County, City of Fullerton, and the CSU Fullerton campus.

Table 10-35: Severe Weather Hazard Probabilities of Future Occurrence for Orange County and CSU Fullerton

Vulnerability to the Hazard

People, structures, and assets on the CSU Fullerton campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The CSU Fullerton campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire CSU Fullerton campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within the CSU Fullerton campus are at risk from severe weather. There are approximately 49 buildings on the main campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazards are $453,119,067 for 38 buildings, but are unknown for the remaining 11 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at the CSU Fullerton campus varies throughout the day. As of Fall, 2019, CSU Fullerton had 39,868 students and 3,736 faculty and staff. All are at risk from severe weather events, with 43,604 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to the CSU Fullerton campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU Fullerton.

| Santa Ana Wind | 32 | Highly Likely |
| Sundowner Wind** | 2 to 3 | Not Rated |
| ** Severe Weather Hazard | | Highly Likely |

** Note: The Diablo and Sundowner wind hazards are not present in Orange County, and therefore are not rated for probability of future occurrence. They are included here for information purposes only.
It is evident that the CSU Fullerton campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
10.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Fullerton campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
Table 10-36: High level summary of campus populations of concern

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (housing insecurity), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (undocumented, DACA, etc.), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as Very High, High, Medium, Low
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as Yes, No, In Progress, NA

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following is an interview note of interest:

- International students have little support networks if impacted because no social network to fall upon; some have language barriers in a crisis and [have difficulty] being able to communicate.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.
In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\textsuperscript{176} Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\textsuperscript{177} Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to

water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.  

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, 

social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitoes that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has
been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 179

**Hazardous Materials**

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for

---

Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

---

180 https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such as heart disease, lung disease, or asthma. Those most vulnerable include the medically fragile, elderly, and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership, and tree canopy.

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes, and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure, and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

11.1 University Profile

University History

Humboldt State University is a public institution of higher learning and part of the 23-campus California State University system. The University was founded in 1913 as a teacher’s college, and over the last 100 years, Humboldt State grew from an institute of higher education focused solely on teacher education to an accredited comprehensive university with extensive research facilities. CSU Humboldt has been known as Humboldt State University since 1974. Since 2013, Humboldt State has been designated as a Hispanic-Serving Institution (HSI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The president and provost are directly supported by the Office of Academic Affairs Leadership Team, which advises and assists the Provost and Vice President of Academic Affairs in the determination of fund and personnel allocations and other administrative matters for the academic sector. Additionally, it serves as a channel of communication both to and from the faculty members in the various colleges. The Leadership Team consists of the University Provost and Vice-Provost, as well as Vice-Presidents, Deans, and Directors of various Humboldt State’s executive departments.

The president is also supported by three (3) Advisory Groups. They are: The Diversity, Equity and Inclusion Council (DEIC), the President’s Community Advisory Committee (PCAC), and the Native American Advisory Council.

The Diversity, Equity and Inclusion Council (DEIC) works in partnership with the Office of Diversity, Equity and Inclusion (ODEI) to provide advisory council and leverage expertise to create institutional and systemic change collectively. The DEIC assists the ODEI in making recommendations and raising awareness of ways to improve Humboldt State’s diversity, equity and inclusion efforts.

The President’s Community Advisory Committee (PCAC) members are appointed by the President to bring their professional perspectives to help inform decision making. Members provide important advice to help guide University priorities, community outreach and relations, governmental affairs, athletics, and other university matters. Membership is based on professional affiliation or leadership role, and members hold two-year staggered terms.
The Native American Advisory Council serves as a communication conduit and assists in developing mutually beneficial partnerships among Humboldt State University, the Native American community, and Tribal Nations. The Council provides perspectives and advice on the University’s collaborations with Native American communities, tribal nations, and tribal organizations in the region. Council members advise the President on matters of importance to Native communities as they relate to the University.

University Mission

The campus mission is, “Humboldt State University is a comprehensive, residential campus of the California State University. We welcome students from California and the world to our campus. We offer them access to affordable, high-quality education that is responsive to the needs of a fast-changing world. We serve them by providing a wide array of programs and activities that promote understanding of social, economic and environmental issues. We help individuals prepare to be responsible members of diverse societies.”

Humboldt State’s Values present 12 principles to reach its mission by focusing on providing the possible education relevant to today’s world, prioritizing teaching excellence, dynamic approach to cutting edge education, intellectual growth, debate and dialogue, responsible action, environmentally, economically and socially responsible in the quest for viable and sustainable communities. Additionally, curriculum is relevant, collaborative and responsive to our geographical location, learning from Native cultures, the unique ecosystem and special communities of the region, community involvement and inclusivity. The university is divided into three colleges: the College of Arts, Humanities, and Social Sciences; the College of Natural Resources and Sciences; and the College of Professional Studies. It offers 48 types of bachelor’s degrees, 12 different master’s degrees, 61 minors, and 13 credentialed programs.

University Location

Humboldt State University is located in Arcata, California (population 18,801), a coastal city in northern California’s Humboldt County (population 135,558). It is the northernmost campus of the CSU’s 23 campuses. The campus is situated on a hillside at the edge of a coast redwood forest, and has commanding views overlooking Arcata, much of Humboldt Bay, and the Pacific Ocean.

University Population

Humboldt State University typically exceeds 6,900 students with over 6,400 as undergrads. Humboldt State University offers 51 majors and 12 graduate programs in three Colleges. Humboldt State University employs 534 faculty members. White students make up 43% of Humboldt State University students, with Latino students making up the second most populous group at 34%.
11.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

11.3 Hazard Identification and Risk Assessment

Overview of Humboldt State University History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive
accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s *How-To Series*, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered XX hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 11-1 (following).

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely**- 76%-100% that the hazard would occur annually.
- **Likely**- 50%-75% that the hazard would occur annually.
- **Possible**- 11%-49% that the hazard would occur each annually.
- **Unlikely**- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent.¹ They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions.² The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.³

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)⁴

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 11-2 below.)

(Source: Interviews with CSU campus staff at CSU campuses and at CSU Chancellor’s Office.)
Descriptions of Identified Communicable Disease Hazards at Humboldt State

Humboldt State has identified five (5) communicable disease hazards that have had the greatest impact on campus – COVID, Measles, Norovirus, Influenza, and STDs. The following are brief descriptions of the communicable disease hazards at Humboldt State.

COVID-19 (SARS-CoV-2)

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It’s not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death. 5

Meningitis

Meningitis is an inflammation of the fluid and membranes (meninges) surrounding the brain and spinal cord. The swelling from meningitis typically triggers signs and symptoms such as headache, fever and a stiff neck. Early meningitis symptoms may mimic the flu (influenza). Symptoms may develop over several hours or over a few days.

Most cases of meningitis in the United States are caused by a viral infection, but bacterial, parasitic and fungal infections are other causes. Some cases of meningitis improve without treatment in a few weeks. Others can be life-threatening and require emergency antibiotic treatment. Bacterial meningitis is particularly serious and can be fatal within days without prompt antibiotic treatment. Delayed treatment also increases the risk of permanent brain damage or death.6

Measles

Measles (also known as rubeola) is a highly contagious childhood infection caused by a virus. The measles virus replicates in the nose and throat of an infected child or adult. Then, when someone with measles coughs, sneezes or talks, infected droplets spray into the air, where other people can inhale them. The infected droplets may also land on a surface, where they remain active and contagious for several hours. The virus is contracted by putting touching one’s nose, mouth, or eyes after touching the infected surface.

Measles can be serious and even fatal for small children. The disease still kills more than 100,000 people a year worldwide, most under the age of 5. However, as a result of high vaccination rates in general, measles hasn’t been widespread in the United States for more than a decade. 7

Influenza (Including sub-type H1N1/Swine Flu)

Influenza is a viral infection that attacks the respiratory system (i.e., nose, throat, and lungs). Influenza viruses travel through the air in droplets when someone with the infection coughs, sneezes or talks. Influenza is transmitted either by inhaling virus-laden droplets directly, or by coming into physical contact with an object (e.g., telephone or computer keyboard) and then transferring the virus to the eyes, nose or mouth. People with the virus are likely contagious from about a day before symptoms appear until about five days after symptoms begin.

Common signs and symptoms of the flu include: fever, aching muscles, hills and sweats, headache, dry and persistent cough, shortness of breath, tiredness and  

weakness, runny or stuffy nose, sore throat, and eye pain. (Vomiting and diarrhea are also influenza signs and symptoms, but these are more common in children than in adults.)

Influenza viruses are constantly changing, with new strains appearing regularly. As a result, antibodies against influenza viruses that have been encountered in the past may not offer protection from new influenza strains, as the new strains can be very different viruses from previous strains. 8

H1N1 Flu (Swine Flu)

The H1N1 flu, commonly known as swine flu, is a type of influenza A virus and is one of several flu viruses strains that can cause the seasonal flu. It is primarily caused by the H1N1 strain of the flu (influenza) virus. Symptoms of the H1N1 flu are the same as those of the seasonal flu.

The H1N1 virus is a combination of viruses from pigs, birds and humans that causes disease in humans. The virus enters your body when you inhale contaminated droplets or transfer live virus from a contaminated surface to your eyes, nose or mouth. It then infects the cells that line your nose, throat and lungs. 9

Tuberculosis

Tuberculosis (TB) is a potentially serious infectious disease that mainly affects the lungs. Tuberculosis is caused by bacteria that spread from person to person through microscopic droplets released into the air. This can happen when someone with the untreated, active form of tuberculosis coughs, speaks, sneezes, spits, laughs or sings.

Although tuberculosis is contagious, it's not easy to catch. It is more likely for someone to get tuberculosis from a close family member or coworker than from a stranger. Most people with active TB who have had appropriate drug treatment for at least two weeks are no longer contagious.

Many strains of tuberculosis resist the drugs most used to treat the disease. People with active tuberculosis must take several types of medications for many months to eradicate the infection and prevent development of antibiotic resistance.10

Norovirus

Norovirus is a highly contagious virus commonly spread through food or water that is contaminated by fecal material during food preparation or by contaminated surfaces.

Specifically, this virus can be transmitted through: consuming contaminated food, drinking contaminated water, and touching one’s hand to one’s mouth after the hand has been in contact with a contaminated surface or object.

Norovirus can also be transmitted through close contact with an infected person.

Norovirus infections occur most frequently in closed and crowded environments such as hospitals, nursing homes, child care centers, schools and cruise ships. Noroviruses are difficult to kill off because they can withstand hot and cold temperatures and most disinfectants.

Symptoms such as diarrhea, stomach pain and vomiting typically begin 12 to 48 hours after exposure, and usually last one to three days. Most people recover from norovirus completely without treatment. However, for some people — especially infants, older adults and people with underlying disease — vomiting and diarrhea can be severely dehydrating and require medical attention. 11

Mumps

Mumps is a viral infection that primarily affects saliva-producing (salivary) glands that are located near the ears. Mumps can cause swelling in one or both of these glands, and is contracted by breathing in saliva droplets from an infected person who has just sneezed or coughed. Mumps can also be contracted from sharing utensils or cups with someone who has mumps.

Complications of mumps, such as hearing loss, are potentially serious but rare. There’s no specific treatment for mumps.

Mumps outbreaks far less common than they used to be, but can affect people who aren’t vaccinated – especially in close-contact settings such as schools or college campuses.12

E. Coli

Escherichia coli (E. coli) bacteria normally live in the intestines of healthy people and animals. Most types of E. coli are harmless or cause relatively brief diarrhea. But a few strains, such as E. coli O157:H7, can cause severe stomach cramps, bloody diarrhea and vomiting. The E. coli O157:H7 strain belongs to a group of E. coli that produces a powerful toxin that damages the lining of the small intestine. Potential sources of exposure to E. coli O157:H7 include contaminated food or water – especially raw vegetables and undercooked ground beef – and person-to-person contact.

Signs and symptoms of E. coli O157:H7 include diarrhea (which may range from mild and watery to severe and bloody), stomach cramping, pain or tenderness, and nausea and vomiting. Infection can occur anytime from one day to one week after exposure to the bacteria, but usually begin three or four days after exposure.13

**Sexually Transmitted Diseases (STDs)**

Sexually transmitted diseases (STDs) are generally acquired by sexual contact. STDs can be caused by: bacteria (gonorrhea, syphilis, chlamydia), parasites (trichomoniasis), or viruses (human papillomavirus, genital herpes, HIV). The organisms (bacteria, viruses or parasites) that cause STDs may pass from person to person in blood, semen, or vaginal and other bodily fluids. Sometimes STDs can be transmitted non-sexually, such as from mother to infant during pregnancy or childbirth, or through blood transfusions or shared needles.

STDs can have a range of signs and symptoms, including: sores or bumps on the genitals or in the oral or rectal area, painful or burning urination, pain during sex, soreness or discharge in genital areas, sore, swollen lymph nodes, particularly in the groin but sometimes more widespread, fever, lower abdominal pain, or rash over the trunk, hands or feet. Signs and symptoms may appear a few days after exposure, or it may take years before any noticeable problems occur, depending on the organism. STDs don’t always cause symptoms, and may go unnoticed until complications occur or a partner is diagnosed.14

**Location of the Hazard**

Communicable diseases have the potential to affect the entire Humboldt State planning area equally. As a result, the communicable disease hazard can be found at the Humboldt State University campus located in Arcata, CA (Humboldt County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) Humboldt State are at risk of exposure to the communicable disease hazard. 15

**CSU Student Housing Locations and Populations**

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e.,

---

15 California State University. About CSU. Retrieved 04.30.2021 from: https://www2.calstate.edu/csu-system/about-the-csu;
just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For Humboldt State, approximately 9% of its 6,983 enrolled students or 628 students reside in student housing. Table 11-4 shows the number of students that were living in CSU-campus-owned housing in Fall, 2019, prior to the COVID-19 pandemic.

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 11-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

17 California State University. CSU Campus Match. Retrieved 04.30.2021 from: https://www2.calstate.edu/attend/campuses/campus-match/Pages/campus-match.aspx
The Extent of Humboldt State Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Measles, Norovirus, Influenza, STDs at Humboldt State. Measles would be classified at the BSL-2 containment level, Norovirus would be classified at the BSL-2 containment level, Influenza would be classified at the BSL-2 or BSL-3 containment level (depending on the strain), and STDs would be classified at either the BSL-2 or BSL-3 containment level (depending on the STD). 19

The Extent of Humboldt State COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3. 20

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 108 cases of COVID-19 at Humboldt State. CSU-campus-specific

---

COVID-19 case data for Humboldt State can be found in the “History of the Hazard” section below.

Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 11-5 and 11-6 show campus-level and county-level COVID-19 case data for Humboldt State. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Table 11-4: Humboldt State COVID-19 Case Data (as of (03/19/2021)21

**HSU Students**: These results are for students (on- and off-campus residents and athletes) who were tested at HSU’s Student Health Center only. Figures do not include results of tests conducted by a private lab, and may not reflect the total number of affected students.

**HSU Employees**: Humboldt County Public Health will only notify HSU if an employee has tested positive for COVID-19 and had contacts with the campus community that could have led to transmission. HSU will report when we are notified of positive cases in employees, but this may not reflect a total number of affected employees.

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including Humboldt State. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of Humboldt State students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including Humboldt State) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).23

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

22 Humboldt County Health. Retrieved on 03.19.2021

Table 11-6: WHO Risk Group Characterization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 11-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall into these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

---

### Table 11-7: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

---

These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

**Probability of Future Occurrence of the Hazard**

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.

Table 11-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:
Table 11-8: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s system-wide probability ranking (below) reflects the ranking at the individual CSU campus level unless noted otherwise.

Table 11-9: Probability of Future Occurrence of Communicable Disease Hazard for CSU System

### Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at Humboldt State campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. As of Fall 2019, Humboldt State University had 6,983 students as well as additional faculty and staff. Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree in the current COVID-19 pandemic on the campus.

### Estimate of Potential Losses

#### COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other

---

communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including Humboldt State) are at risk of developing an extreme incidence of COVID-19 and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. Several CSU campuses saw refund losses surpass $10 million. (See Figure 11-2 below for the economic impact to Humboldt State)

---

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table CD.10) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

**Vulnerability Assessment Conclusions**

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.
At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems. See Table CD.11 (below) for the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

*Please Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system, including Humboldt State. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.
Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Dam and Levee Failure**

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

---

Levee failures can vary from over toppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

Humboldt County is home to a variety of flood control facilities and levee systems throughout the county. Arcata sits between the Arcata Bay and the outlet of the Mad River into the Pacific Ocean. There are dam and levee facilities in Humboldt County to the north, west, and south of the Arcata including levees that separate the tidal influences of the bay from the community.
The county is additionally downstream of facilities located in other counties. The primary dam facility that could present a threat to the Humboldt State University campus community is in neighboring Trinity County containing significant amounts of water. The Robert W Matthews Dam regulates the Mad River 70 miles upstream eventually feeding into the Pacific Ocean. The Mad River is 2 ¼ miles north of the campus. A failure of this facility is expected to produce inundations that cover sizable areas through the Mad River Valley including Blue Lake and north Arcata. The Humboldt State University campus is not located within the Robert W Matthews Dam inundation area but the sole transportation routes to the north and east of the Eureka region are found within the inundation zone.

Figure 11-4: RW Matthews Dam Breach Inundation Map

---

36 California Department of Water Resources, Dam Breach Inundation Map Publisher, https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
Levees have been constructed to protect portions of Humboldt County outside of Arcata. A series of levees have been constructed to protect lands alongside the Arcata Bay providing protection from tidal and coastal influences. Additionally, levees line parts of the Mad River north of Arcata. The Humboldt State University campus is not located in a levee protected area.
Figure 11-5: Dams and Levees near Humboldt State University

Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.

- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

<th>Hazard Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mad</td>
<td>Robert W Matthews (Trinity County)</td>
<td>60,200af</td>
<td>High Hazard</td>
</tr>
</tbody>
</table>

The Humboldt State University campus lies outside of the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the Humboldt State University campus is expected to remain out of the inundation area. The inundation area is expected to spread water in areas north of the campus and remain near the Mad River and downstream agricultural fields in proximity to the campus. However, there are transportation corridors including US Highway 101 that lie within the dam inundation zones that could compromise transportation routes and areas the campus community reside or work. Based on these conditions, the planning committee ranks the extent of the dam failure hazard on campus as **Low**.

**Extent – Levee Failure**

Levees are used along numerous flood control channels and other waterways including the Mad River and the Arcata Bay. The Humboldt State University campus lies outside of the levee flood protected area. In the event any of these channels were flowing at elevated levels and a failure of a levee were to occur, the campus would not be directly impacted but the community surrounding the campus would likely experience flood related damages. This specific hazard could alter the ability of the campus to maintain operations. US Highway 101 crosses through the levee protected zones in addition to the dam inundation zone creating a potential for community-wide isolation from access, evacuation, resources, and other services from outside of the Eureka area. Based on these conditions, the planning committee ranks the extent of the dam failure hazard as **Low to Moderate**.

History of the Hazard

There are no records of dam or levee failures in areas that present a threat to the Humboldt State University campus. Humboldt County has not identified a history of dam or levee failures elsewhere in the County.

Potential Impacts of the Hazard

**Dam Failure Impacts**

While the campus is not within a dam inundation zone, transportation routes, critical infrastructure, and campus community members may reside within inundation zones. Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues
Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

Probability of Future Occurrence of the Hazard

Humboldt County remains at risk from dam and levee failure. The location of the Humboldt State University campus downstream on the Mad River from the Matthews Dam containing Ruth Reservoir demonstrates that the potential exists for future dam or levee related issues. However, the dam inundation zone follows the Mad River not in immediate proximity to the campus. The campus is 1 ½ miles from the boundary of the dam inundation zone. Access routes to and from the campus would be impacted.
by a collapse of this facility. There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. However, based on consistent dam and levee monitoring and maintenance protocols, and on historical experience occurrences, the likelihood of this hazard is Low.

The probability of future occurrence for both dam and levee failures is Unlikely.

**Vulnerability to the Hazard**

Given High Priority dam monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. In addition, the campus does not lie within an inundation zone. However, in the unlikely event of a catastrophic failure, the effects of flooding from compromised dams and levees on campus would most likely be limited to indirect or secondary effects in terms of disruption to regional transportation networks and services, and the amount of time to respond to the needs of the campus community prior to inundation will be limited. The distributed placement of levees mostly near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected.

Vulnerability to a dam or levee failure near the Humboldt State University campus will vary depending on the degree of breach or structural failure and when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks.

Some areas of particular vulnerability to dam failure from the Matthews Dam on the campus includes:

- Limited vulnerabilities to the main campus.
- US Highway 101 vulnerable to the effects of dam inundation flows crossing the Mad River limiting access to the Trinidad Marine Laboratory
- US Highway 101 and State Route 299 vulnerable to the effects of dam inundation limits the access to and from the campus servicing northern routes into Oregon and eastern routes into Redding
- Native American lands lie within the dam inundation directly impacting those campus community members residing in these areas
- Campus community members residing in areas north of the Mad River such as McKinleyville and Calville may be isolated from campus

Finally, certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.
Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs are $117,600,736. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at Humboldt State.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the Humboldt State campus, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences would be catastrophic to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.
**Drought**

**Hazard Description**

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for Humboldt State) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified in Humboldt County and the City of Arcata where Humboldt State is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years. 38

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout the planning area and across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire planning equally, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. In addition, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels in California have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. These are applicable concerns for the Humboldt State campus over the long term.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

</tbody>
</table>
Although drought conditions have not been reported at the campus level, historically, drought has been so prevalent in California that its presence is almost continuous, including Humboldt County and the Humboldt State footprint. According to the US Drought Monitor, Time Series data, Humboldt County experienced x periods of drought from 2000-2021, including the severe statewide event from 2012-2017.

Figure 11-6: Periods of Drought in Sonoma County, California, 2000 – 202140

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 41

---

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 11-7: Periods of Drought in State of California, 2001 – 2021

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state, and according to the US Drought Monitor’s Time Series data, on Humboldt County which encompasses the planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2014-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For

example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent. 43

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the region and the county surrounding Humboldt State campus planning area is a reduction in water availability for the municipal area tied to the campus. Other potential impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of Humboldt State to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of agricultural research crops and field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. 44 However, the wildfire hazard is analyzed separately in this plan. (See Section X for coverage of the wildfire hazard).

In reviewing the occurrences of drought for Humboldt County, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012 - 2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to Humboldt State, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark

beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area. 45

At present, drought related damage to campus buildings and infrastructure at Humboldt State has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for Humboldt State is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including Humboldt State. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Probability of Future Occurrence of the Hazard

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that Humboldt State lies within a drought

---

impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the Humboldt State campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state, the county and the Humboldt State planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. 47 In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average.

Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir. 48

**Vulnerability of Populations**

The historical and potential impacts of drought on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the Humboldt State campus.

**Property Vulnerability**

Vulnerabilities include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the Humboldt State campus.

**Natural Environment Vulnerabilities**

Drought vulnerabilities in the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerability throughout California (including Humboldt State) is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought on campus, it is tied to the watersheds in the Sierra region which contribute most greatly to the county’s and the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San

---

Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for Humboldt State’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of Arcata and Humboldt County, such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

In addition to ground motion, there are several secondary hazards that can result from an earthquake including:

Fault Rupture – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

Liquefaction – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at
ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. Humboldt State University is located on the northern California coast on a coastal plain between Arcata Bay and the Mad River. In general, fault systems surround and traverse throughout the Eureka/Arcata region and Humboldt County including the area of Humboldt State University. Throughout the populated areas of Arcata and Eureka and surrounding cities, the ground is saturated with sediment eroded from the hills by means of multiple stream channels. Liquefaction zones rated at moderate susceptibility exist in the majority of Arcata.

The Pacific Plate and the North American Plate come together at the San Andreas/Mendocino Fault 45 miles south of the Humboldt State University campus. In addition to the San Andreas Fault, Humboldt County is home to or near multiple additional fault systems with the potential to generate strong ground shaking. The campus is additionally in close proximity to a series of parallel fault systems that surround the campus. The Fickle Hill, Mad River, McKinleyville, and Trinidad Faults all extend in a southeast to northwest direction from less than ¼ mile north to 5 miles north of the Humboldt State University campus. South of the campus there are additional parallel fault systems including the Little Salmon, Table Bluff, Russ, and Bear River Faults. These fault systems are from 11 to 30 miles south of the campus. The entire Humboldt County Area is saturated with numerous additional faults mostly paralleling the San Andreas Fault to the northwest. These fault systems are located on each side of the campus.
Figure 11-8: Faults located near Humboldt State University

Portions of the Humboldt State University campus reside on areas designated to be liquefaction zones. Campus facilities that are potentially located within the liquefaction zone include the Canyon Complex Residence Halls, Creekview Complex Residence Halls, and the J Parking Lot. Liquefaction zones also exist at the Sunset Avenue overpass over US Highway 101, throughout north Arcata, and surrounding Arcata Bay to include the City of Arcata south of 11th Street.

Extent of the Hazard.

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of
measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale (below) was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:
<table>
<thead>
<tr>
<th>Intensity</th>

<tr>
<td>VIII</td>
<td>Severe</td>
<td>Damage slight in specially designed structures; considerable damage in ordinary substantial buildings with partial collapse. Damage great in poorly built structures. Fall of chimneys, factory stacks, columns,</td>
</tr>
</tbody>
</table>

monuments, walls. Heavy furniture overturned.

| IX | Violent | Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb. Damage great in substantial buildings, with partial collapse. Buildings shifted off foundations. |
| X | Extreme | Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations. Rails bent. |

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.
The Humboldt County Operational Area Hazard Mitigation Plan describes the probability of an earthquake Magnitude of 6.7 or greater in Northern California over the next 30 years is 95%. The Plan indicates that in the Eureka area earthquake activity is a regular occurrence. Based on the earthquake shaking potential in the Humboldt County area, the proximity to the fault systems illustrated above, and the proximity to liquefaction zones, the planning committee ranks the extent of the earthquake hazard on campus as Moderate.

History of the Hazard

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Likewise, Humboldt County also has a long history of earthquake activity. The entire area of Humboldt County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Eureka area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment. The few roadways into and out of the Eureka area are vulnerable to seismic shaking and the resulting landslides that could occur.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals

51 Humboldt County Operational Area Hazard Mitigation Plan, January 2020
minimal time to react and find areas of safety. A moderate earthquake occurring near Eureka could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Eureka or Arcata could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader North Coast region limiting immediate assistance that the campus may normally expect.

Local impacts to the Humboldt State University campus caused by an earthquake could include:

- Damage and secondary fires to commercial buildings to the west of campus
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway system, US Highway 101 is critical link to communities along the coast
- Structural damage to bridges over waterways, flood control channels, and roadways
- Potential for movement of soils along hillsides
- Potential for earthquake generated tsunami threatening the Humboldt and Arcata Bays including the dock location of the R/V Coral Sea and Marine Laboratory in Trinidad
- Isolation of the Trinidad based Marine Laboratory
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to Mad River levees
- Structural damage to levees lining the Arcata Bay
- Structural damage to campus academic and support buildings
- Loss of academic research, documentation, equipment, and materials
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences especially older construction
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Potential reduced capacity to provide services to campus community
Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Humboldt County fault systems surrounding the Eureka region is included in the following table.

The Humboldt County Operational Area Hazard Mitigation Plan describes the probability of an earthquake Magnitude of 6.7 or greater in Northern California over the next 30 years is 95%. The Plan further illustrates that specific to the Eureka area

52 Humboldt County Operational Area Hazard Mitigation Plan 2019, January 2020

earthquake activity is a regular occurrence and the region could see a Magnitude earthquake in the future. 54

Based on the earthquake shaking potential in the Humboldt County area, the proximity to the fault systems illustrated above, and the proximity to liquefaction zones, the probability of seismic ground shaking that would generate damage is considered **Possible**.

**Vulnerability to the Hazard**

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of Humboldt State University places the campus in a mostly rural community near residential, commercial, and industrial areas that is lightly populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to the Northern California Coast region generally surround the area and some cross near the Humboldt State University campus. The campus resides in a region that is exposed to fault systems on all sides. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Elements of the vulnerability to a major earthquake on the Humboldt State University campus will vary depending on when the earthquake were to strike. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

---

54 California Earthquake Authority, California Earthquake Risk Map & Faults By County, https://www.earthquakeauthority.com/California-Earthquake-Risk/Faults-By-County
The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with sheltering and care of those unable or unwilling to return to their homes. Damages to the homes of the members of the campus community may place greater demands on campus resources and capabilities in the short-term period following a seismic event.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. This may be heightened as much of the lower campus has been identified as being within a liquefaction zone. As the Humboldt State University campus is downstream from dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

The North Coast and Eureka / Arcata in particular are lightly populated with modest services immediately available. Humboldt County is served by only two primary surface transportation routes. US Highway 101 extends south to San Francisco and north to Oregon. California State Route 299 is a two-lane undivided highway that connects to Redding. The closest robust out of area services are 143 miles to the east in Redding or Santa Rosa 220 miles to the south. US 101 is often impacted by landslides in heavy weather events. A major earthquake has the potential for rendering these critical lifelines and supply routes inoperable and forcing the campus community to be self-reliant for a period of time.

Finally, certain campus populations will experience greater challenges to a post-earthquake environment. There are significant numbers of members of the community who live in areas most vulnerable to earthquake effects. 63% of Humboldt County residents live in high-risk earthquake areas, 58% of these who live on soils that are vulnerable to dangerous shaking have household incomes less than $50,000 per year, and 13% of those are over the age of 65. 55 Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

55 Humboldt County Operational Area Hazard Mitigation Plan 2019, January 2020
Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $117,600,736.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater Eureka region, the North Coast, and the Humboldt State University campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the Humboldt State University campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding Arcata and Eureka, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major
earthquake would extend the effects of casualties, damages, and other impacts to the broader Northern California Coast region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

Vulnerabilities will be seen in the physical infrastructure on the campus and the human population of the campus community. Campus infrastructure is vulnerable to severe shaking particularly in areas where the ground is loose or susceptible to liquefaction. Specifically older buildings, masonry constructed buildings, and other structures susceptible to shaking related damage are the most vulnerable. Communication systems, computer networks, and other electronic systems may be vulnerable when overwhelmed by increased demand during emergencies or by shaking related damages. The people of the campus community are vulnerable to effects of intense shaking in the form of injuries from falling debris, exposure to secondary floods or fires, loss of employment, extreme disaster induced stress, and loss of access to critical services or social contacts.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.
Erosion

Description of the Hazard
The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.” Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard
Erosion is a hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While coastal erosion can happen in any storm, it is more likely during El Nino events, which occur every 5-7 years. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across those areas of the campus with erosion-prone characteristics.

Other incidents of erosion, such as occurs around buildings, are relatively non-spatial and can occur in any locations with conducive soil structure and a source of movement, such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover.

Extent of the Hazard
Erosion is occurring on the Pacific coastline west of CSU Humboldt. While there is no published scale of severity or extent for this geologic hazard on the CSU Humboldt campus, erosion is likely to occur if conditions are favorable, and given that such conditions have been identified on campus, as well as the history of occurrence (albeit limited) the planning committee ranks the extent of this hazard as Low to Moderate.

History of the Hazard

Erosion hazards have been recorded at the Telonicher Marine Lab and along the coastline. There are no other recorded incidents of erosion on the CSU Humboldt campus.

Coastal erosion can result in severe impacts to infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

**Probability of Future Occurrence of the Hazard**

Erosion is an on-going and dynamic process that occurs regularly. As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. As a result, and in consideration of the potential extent of erosion on campus, the probability of at least a limited degree of erosion taking place in the future is **High** over the long term.

**Vulnerability to the Hazard**

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Humboldt infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion.

In the wider Arcata community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

**Vulnerability Assessment Conclusions**

While the ability to predict future erosion on the CSU Humboldt campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**
The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Heat**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.57

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.58 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feels” hotter. The combination of temperature and humidity is known as the heat index.59

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.60 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.61

**Location of the Hazard**

59 Ibid.

Extreme heat events are a non-spatial hazard and may occur throughout the Humboldt State campus.

Extent of the Hazard

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the low 60s to mid-60s in Arcata, California, where Humboldt State is located. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at the Arcata Eureka Airport was 96° F on September 2, 2017. This was during a statewide heat wave that caused all-time record highs and record highs for September. That said, given the limited history of events and low probability of future events due to the campus’ cooler coastal climate, the planning committee ranks the extent of the hazard as Low.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 11-10 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

---

As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.

</tr>
</tbody>
</table>

Based on no record of extreme heat events on campus, and only 1 event county-wide, along with the County’s established protocols of providing the public with advanced notice of heat events with directives for mitigating impacts, the planning committee ranks the extent of this hazard on campus as Low.

**History of the Hazard**

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there has been only one heat event (July 10, 2002) that has affected Humboldt County since 1990. However, this event did not impact the Arcata area of the county. According to NCDC data, the maximum recorded temperature that day at the Eureka airport was 65° F.

**Potential Impacts of the Hazard**

During an excessive heat event, Humboldt State may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

---

Probability of Future Occurrence of the Hazard

No extreme heat events have impacted the City of Arcata in three decades. Using the scale provided, it is unlikely that the hazard will occur annually. Notably, the Humboldt County Hazard Mitigation Plan also does not include excessive heat as a potential hazard for the county or its jurisdictions.64

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.65 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

CSU Humboldt is aware that they are unlikely to face an extreme heat event. Accordingly, most campus buildings do not have air conditioning. This could be problematic for the campus even if Humboldt County were to face even a mild heat wave, as there would be limited ways for students and staff to cool down, and vulnerable populations would be at higher risk of heat-related conditions.

Although this is not a hazard that the campus will experience regularly, CSU Humboldt may want to consider investing in back-up cooling options.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage, and in Humboldt County, heat events are rare.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the CSU Humboldt campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed approximately 1.5 degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.\textsuperscript{66}

**Cold**

**Description of the Hazard**

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.\textsuperscript{67}

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.\textsuperscript{68} This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underly tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes.\textsuperscript{69} It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases.\textsuperscript{70} The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

\textsuperscript{67} National Weather Service. *Stay Safe in the Extreme Cold*. Retrieved 01.29.21 from: https://www.weather.gov/dlh/extremecold

\textsuperscript{69} Mayo Clinic. *Frostbite: Overview*. Retrieved 01.29.21 from: https://www.mayoclinic.org/diseases-conditions/frostbite/symptoms-causes/syc-20372656

\textsuperscript{70} Ibid.
Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6° F. Hypothermia occurs when your body temperature falls below 95° F. As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

Location of the Hazard

Extreme cold events are a non-spatial hazard, and may occur throughout the Humboldt State campus.

Extent of the Hazard

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in the City of Arcata are typically in the low 40s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in Arcata was 11° F on February 25, 2008. That said, given the limited history of freeze/frost events, no history of extreme cold, and low probability of future events, the planning committee ranks the extent of the hazard as Low.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30° F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure xx (following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow).

---

In 2011, the National Weather Service introduced an experimental program that issued warnings for extreme cold events, independent of other severe weather warnings. The test areas included North and South Dakota and Minnesota. However, in 2012, after a single season of use, the program was abandoned, based on reports of confusion among test audiences. Based on the fact that Humboldt County has had just three cold/wind chill or frost/freeze events dating back to 1998 and extreme cold events, the planning committee ranks the extent of the hazard as Low.

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, Humboldt County has had three cold/wind chill or frost/freeze events dating back to 1998, but no extreme cold hazards. [Records for this hazard were first recorded in 1996].

---

Potential Impacts of the Hazard

Should an extreme cold event occur, Humboldt State might experience impacts due to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

Probability of Future Occurrence of the Hazard

The City of Arcata has experienced cold/wind chill and freeze/frost events, but has never experienced an extreme cold event. Due to the City’s location and its temperate climate, it is unlikely that this hazard will occur annually at Humboldt State.

Vulnerability to the Hazard

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more likely to suffer illness or death as a result. This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

CSU Humboldt is aware that they face little potential for extreme cold events. In the case of occasional freeze/frost events, if the temperature drops below 32° for six hours or more, the campus will issue warnings to students and staff about keeping the heat running at a certain temperature in order to protect pipes from freezing and bursting.

Based on the previous historical occurrences of extreme heat events, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

**Vulnerability Assessment Conclusions**

While the ability to predict future extreme cold events at the CSU Humboldt campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), areas in northern California have warmed approximately 1.5 degrees on average over the last century, with less rainfall. This may lead to fewer frost/freeze events in the future.75

**Identified Data Limitations**

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

**Flood**

**Description of the Hazard**

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Floods can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.
- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric River**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.

Figure 11-12: Science behind Atmospheric Rivers

---

76 National Oceanic and Atmospheric Administration, “What are atmospheric rivers?”, https://www.noaa.gov/stories/what-are-atmospheric-rivers
Humboldt County is home to a variety of waterways, flood control facilities, and levee systems along the Mad River and the Eureka Plain surrounding Arcata Bay. The Mad River is one of the rivers that drains the mountains of Humboldt County and Ruth Lake in Trinity County. The Mad River drains into the Pacific Ocean 2 ½ miles north of the Humboldt State campus. The Eel River drains the Northern Coast Ranges and the southern portions of Humboldt County and northern Mendocino County. The Eel River drains into the Pacific Ocean 12 miles south of Eureka.
The Mad River is a year-round flowing river draining a 497 square mile watershed of the North Coast Range. The river feeds into the Pacific Ocean after flowing for 113 miles. The Ruth Lake reservoir in Trinity County is 70 miles upstream providing the only regulated section of river between the campus and the lake. The Jollie Giant Creek is a small creek flowing along the north side of the campus from the hills immediately to the east. The Humboldt State University campus is situated slightly higher in elevation on a hillside from the coastal plain.

Levees have been constructed to protect populated and agricultural areas of Arcata near the Humboldt State University campus. Levees are used in containment of river rise, tidal influence, and barriers from sloughs in areas of the coastal Eureka Plain floor. The Humboldt State University campus is located outside of any designated levee protected zone identified in the National Levee Database77 affecting no facilities.

---

on the campus. The Humboldt State University campus lies mostly in Zone X and outside of Special Flood Hazard Areas and levee flood protected areas.

Extent of the Hazard

The Humboldt State University campus is located mostly in a designated Zone X: Area of Minimal Flood Risk. There are large portions of the community surrounding the campus on the south, west, and north sides located within a Zone AE: 1% Annual Chance Flood Hazard. The access routes into and out of the campus servicing locations in Oregon, south to Eureka and beyond, and east to Redding are found in areas designated as Zone AE: 1% Annual Chance Flood Hazard placing these transportations routes in threatened areas. Because the Humboldt State University campus lies outside of Special Flood Hazard Areas and levee flood protected areas, flooding does not substantially alter the ability of the campus to maintain operations as the distance to levee protected channels exceeds the protection zones.

Based on the above conditions, the planning committee ranks the extent of the hazard on campus as \textbf{Low}.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 11-21: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>

### History of the Hazard

Flooding in Arcata and Eureka and the broader California North Coast region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the Humboldt State University campus. No record of flood events are reported for the campus, and

#### Zone A
- **1%**
- Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.

#### Zone AE
- **1%**
- Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, BFEs derived from detailed analyses are shown at selected intervals within these zones.

#### Zone AH
- **1%**
- Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.

#### Zone AO
- **1%**
- Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.

#### Zone X (shaded)
- **0.2%**
- Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.

#### Zone X (unshaded)
- **Undetermined**
- Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.
only isolated flooding and small-scale ponding occasionally occurs during heavy rainfall events.

Humboldt County Operational Area Hazard Mitigation Plan 2019, January 2020
The following flood summaries are provided by the Humboldt County Operational Area Hazard Mitigation Plan.

The December 1955 flood occurred following weeks of above-normal precipitation in the county, with rainfall measurements reaching as high as 24 inches over three days in Cummings. Damage in the Eel River Basin exceeded $22 million, with one reported fatality and 43,000 acres flooded. Heavy debris carried by high velocity river flows caused the majority of the damage.

Heavy rains accompanied by runoff from an unusually large snowpack led to flooding of the Mad and Eel Rivers in December 1964. Total damage reached $100 million, with entire communities being destroyed (including Pepperwood, the site of the 1955 fatality) and 19 fatalities reported. Millions of board feet of lumber, thousands of acres of farmland, and 4,000 head of livestock were lost, causing a tremendous economic impact on the county.

Flooding in January of 1995 caused one death and over $15 million in damage. Flood damage was reported throughout much of the county, but the most severely impacted area was the Eel River Valley. The county received both a governor’s proclamation and a presidential disaster declaration.

The March 1995 Flood event saw continued winter storms and flooding in the months following the January 1995 event caused an additional $2 million in damage throughout the county. The county received a second presidential declaration in March 1995.

The January 1997 flood was the fifth largest flood on record in Humboldt County. The U.S. Forest Service reported that the storms of December and January produced two to three times the monthly average precipitation on the Klamath National Forest. Most the reported damage was from landslides and road failures. The estimated damage to road facilities exceeded $35 million within the Klamath National Forest.

Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities, including on campus power generation
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Threat, inundation, or damage to on campus childcare facilities and occupants
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Additionally, individuals unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

Humboldt County is determined have considerable portions of the county to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common in the Eureka area with winter storms off the Pacific Ocean. The area surrounding the Humboldt State University campus does not generally promote conditions for flood waters to accumulate. The campus is located on a hillside allowing drainage to occur. There are specific buildings and areas of the campus that have a greater risk for isolated flooding. The Humboldt State University campus is located within a Zone X Special Flood Hazard Area (Area of Minimal Flood Hazard) but is surrounded on the south, west, and north by areas classified as Zone A (Area Inundated by 1% Annual Chance for Flooding). Access into and out of the campus will
likely be compromised in flooding events in these areas. The Zone A areas are as close as ¾ of a mile from the campus. The Zone A areas are a result of the influences of the Arcata Bay and the Mad River. However, there is also a historic record of isolated urban or street flood events provides a demonstration of potential flood activity occurring on the campus.

Based on these conditions, the planning committee ranks the probability of future occurrence for flooding as Unlikely annually, but Possible over the long term.

**Vulnerability to the Hazard**

The Humboldt State University campus is most likely subject to minor effects of flooding resulting primarily from localized flooding and ponding from excessive precipitation and isolated strong storms. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of Arcata due to overflow or damage to flood control systems such as the barriers surrounding the edge of Arcata Bay of levees protecting the community from Mad River rises. The flood control channels and drainage systems that surround the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the Humboldt State University campus will vary depending on when the flood were to occur, and the location of people and assets within any low lying areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community located in low lying buildings may become trapped on campus depending on the level of flooding occurring on surface streets. However, in rare, region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

Humboldt State University is in proximity to residential neighborhoods and commercial areas. In the unlikely event that these areas are inundated with flood water, the potential for release of contaminants, hazardous materials, biological contaminants, and other chemicals presents possible exposures to individuals from the campus community. Any flood waters left standing in the area would pose a significant vulnerability to the campus community remaining on campus in potential health and safety effects.

Some campus buildings and infrastructure in low lying areas might be vulnerable if low probability, large-scale flooding were to reach the university. Campus utilities, including the on-campus power plant, and communication capabilities would be impacted by flood waters rendering them disabled. A flood covering a large portion of the city would likely affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive
restoration or demolishing. The residents of the on-campus residence halls in low lying areas may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. In such areas, flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

The campus community and its resource needs are vulnerable to geographic isolation during a low probability/extreme flood scenario. The Eureka and Arcata region are served by three routes into and out of Humboldt County. Extensive flooding may result in inundated transportation routes or routes that have damaged by flood erosion. Resources and services needed to support the community could be unable to use ground transportation into the area. Likewise, members of the campus community, specifically students from out of the area, might be isolated from home until repairs are made or alternative transportation methods are provided.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations might need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $117,600,736. However, it is unlikely for flood to cause destructive losses to the entire campus.

11-90
### Vulnerability Assessment Conclusions

The primary vulnerabilities to flood are exposed mostly by localized flooding from isolated or large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. The consequences of widespread flood could generate disaster effects to communities including Arcata. While the Humboldt campus is removed from designated flood zones, the campus remains vulnerable to localized floods due to heavy rains or overflow of campus creeks.

The potential for flooding on campus and the surrounding area generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

### Identified Data Limitations

Lack of comprehensive historic flooding occurrences, missing campus structural replacement costs, and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.
Hazardous Materials

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” 79 Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

Fixed Hazardous Materials Incident: A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

Transportation Hazardous Materials Incident: A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

Pipeline Incident: A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

---

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from *Natechs* or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. The planning committee indicates that chemicals are located in the science lab, but otherwise no known hazardous materials are present on campus. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city and county of Humboldt and reflect different types, configurations and scales dispersed across these geographic areas.

---

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

However, for the CSU – Humboldt planning committee, although only small chemical spills have taken place on campus, and hazardous materials are limited to chemicals in the science building, a gas pipeline, a rail line, chemical industry and hazardous waste sites are located close to the campus. Based on these factors, along with the types and levels of hazardous materials in the larger community, it is prudent to rank the extent of the hazard for the CSU – Humboldt campus as Moderate, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

For more details on specific hazmat events, please refer to the local, county and/or multi-jurisdictional hazard mitigation plans where CSU campuses are located at:

According to the campus planning committee, a few small chemical spills have taken place in the science building on the CSU – Humboldt campus, though none recently and none required evacuation.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – Humboldt campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. 86 Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

Potential Impact of the Hazard (Natechs)

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Humboldt) is at risk of potential impact from a natural-technological (combined impact) event, especially one triggered by tsunami or earthquake.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the CSU – Humboldt campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low to Moderate - the campus has experienced small-scale chemical spills, however, hazardous waste and chemical sites, a rail line and a gas pipeline are close to the campus. That said, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the CSU – Humboldt campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: chemicals are present in the science lab, and hazardous waste and chemical sites, a rail line and a gas pipeline are close to the campus.
chemicals or hazardous waste, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Humboldt leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.
Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Humboldt) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Humboldt County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Humboldt campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.
Identified Data Limitations

The CSU – Humboldt planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

Landslide

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow.88 These landslides

may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen below. Based on the Figure below, the Humboldt State campus is connected to areas with moderate to high susceptibility to landslide.
Humboldt County is mountainous and in a high seismic risk zone, which leads to significant landslide risk county-wide. In Arcata, landslides are more likely to occur in the steep slopes to the east and along the coastline. However, the indirect impacts of landslides may cover a larger geographical extent. Based on the campus’ close proximity to landslide hazard zones, and the history of Federally Declared landslide related events in the county, the planning committee ranks the extent of the landslide hazard for the campus as Moderate.

History of the Hazard

NOAA has recorded three occurrences of debris flow in Humboldt County, all occurring in 2005. FEMA has declared nine major disasters involving landslides, mudslides, or mud flows since 1982. During the winter storm of 2005-2006,
widespread landslide damage occurred in Humboldt County, impacting every major transportation corridor and cutting much of the county off from its neighbors. A goods shortage resulted in Arcata, as well as service and utility disruptions. That said, no landslides have occurred on or immediately adjacent to the campus.

Potential Impacts of the Hazard

CSU Humboldt may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are also often triggered by other natural hazards, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in Humboldt County and therefore are highly likely to occur in the future. Given the location of the campus directly adjacent to the landslide zone, and the historical occurrence of landslides in the county, the planning committee ranks the annual probability of the landslide hazard on the campus as Possible.

Vulnerability to the Hazard

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. The Humboldt State campus may contain building and infrastructure vulnerabilities to some degree, and exhibits access route vulnerabilities due to its close proximity to moderate and high hazard zones. See the landslide location map in relation to the campus along with landslide severity zones identified.

Any population proximal to a landslide when it occurs is vulnerable to its impacts.
Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Humboldt.

Vulnerability Assessment Conclusions

Landslides could impact the campus in a variety of ways, related to both direct and indirect impacts to buildings, infrastructure, transportation and utilities. In turn, utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the CSU Humboldt campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.13
Power Outage

Description of the Hazard

Humboldt, California is a county in Northern California. Humboldt County is made up by the Arcata, Eureka, and Fortuna areas. Humboldt State, specifically, is located in Arcata, adjacent to Humboldt Bay. Humboldt is categorized as a rural area of California with about 110 miles of coastline along the Pacific Ocean.

Humboldt State University would experience disruptions in most aspects of modern life, and almost all aspects of rural life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly populated areas, like Humboldt, with basic services, such as electricity or sanitation with an inability to manage. These interruptions can be cascading effects from other hazards, such as the result of major windstorm, floods, wildfires or caused by intentional disruption of transmission lines.

In the event of a power outage at Humboldt State University, some possibilities from a power outage event can disrupt day-to-day operations to the campus, like in-person classes, potentially impede, or limit digital communications, interrupt telephonic or radio communications, make elevators, entry ways and other devices malfunction or inoperable. Additionally, impacts can occur to the surrounding campus community by forcing temporary closures of local restaurants and other types of vendors. Additionally, thousands of Humboldt State student residents in on-campus housing would also be affected by a power outage on campus and students residing in off campus housing close to the university, as well.

Additionally, a severe outage to Humboldt County or the City of Arcata would also directly affect the campus and the community creating social, economic, and potential health and safety impacts.

An electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions:

- Planned: Some disruptions are intentional and can be scheduled based maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire
system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, as a hazard, it has the potential to affect the entire planning area equally. Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO) is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities. CAISO is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, and history of occurrence on campus. Campus operations maintain safety precautions, situational awareness, access to emergency power generators and other protocols for
managing power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard

The Humboldt State Threat Hazard Identification Risk Assessment reports that the university has experienced power outages impacting the university. The City of Arcata has experienced power outages as secondary events due to disasters, like wildfires, thunderstorms, and floods. Humboldt State has experienced intermittent power outages due to storms. The campus will lose power for approximately 6-8 hours. University resident halls and dining are relieved by the impact of the power outage through the use of power generators. Other campus items effected by a loss of power are 8 fish tanks up to a monetary value of 8 million dollars.

The following power outages occurred as a cascading event.

The Humboldt State THIRA states that when Humboldt County experiences a power outage, the university is also affected. The following are some power outage events that have affected the university in the recent years.

- October 9, 2019: Humboldt State University closed its campus and cancelled all classes and activities through Thursday of that week as an extended power outage affected 60,000 Humboldt County residents, including the campus community.
- October 29, 2019: Humboldt State University closed and cancelled classes due to a countywide power shutoff due to a wildfire.
- November 26, 2019: Strong winds impact Humboldt County and cause power outages throughout the county including Humboldt State University. PG&E, the areas electric utility provider, is addressing the issues creating the outage including stabilizing and repairing downed power lines.
- January 17, 2020: Humboldt State University closed campus due to a power outage. All HSU activities, on-and-off campus were cancelled, with the exception of an orientation for new students.

Potential Impacts of the Hazard

Instructors, campus residents, staff and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations if a significant event occurs. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.
Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

Finally, disruptions involving floodwater can create significant and lengthy power outages with challenging issues preventing immediate remedies for repair. Additionally, power outages create caveats in emergency personnel reaching crisis events due to possible traffic build up due to streetlights and traffic lights also malfunctioning.

Probability of Future Occurrence of the Hazard

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The campus, the City of Arcata and Humboldt County experience such outages. As such, the probability ranking for the campus is Likely.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.
Vulnerability to the Hazard

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

To mitigate against power outages, the university has placed risk management strategies to manage future occurrences, like building a micro-grid project that provides enough power generation for minimal operations and obtaining sufficient generators for these issues.

Estimate of Potential Losses

The data provided by Humboldt State University does not report any value for potential losses due to power outage.

Vulnerability Assessment Conclusions

The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Channel Islands. Safety and operations protocols center on the following “direct impact” set of concerns:

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The vulnerable population (especially students with physical disabilities) may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors, and locks and lights may impede on a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

Humboldt State did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
**Tsunami**

**Description of the Hazard:**

A tsunami is a wave triggered by any form of land displacement along the edge or bottom of an ocean or lake. Land displacement can be in the form of submarine landslides or submarine dip-slip faults. These types of faults cause ruptures that result in seafloor uplift or down-drop. This mass movement translates to a tsunami or gravity wave within the overlying water at the surface.

Tsunamis travel radially outward from the area of initiation. The size of a tsunami is proportional to the mass that moved to generate the tsunami. As a tsunami approaches the shore and the depth of the water column decreases, the energy in the wave pushes the wave crest above the water surface resulting in a larger wave height. Wave runup is the elevation above mean sea level on dry land that a tsunami reaches. Run-up is what causes inundation of coastal areas that are below the run-up height.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing severe damage to coastal development. At the shoreline, tsunamis may take the form of a fast-rising tide, a cresting wave, or a bore (a large, turbulent wall-like wave). The bore phenomenon resembles a step-like change in the water level that advances rapidly (from 10 to 60 miles per hour). The first wave is usually followed by several larger and more destructive waves.

**Location of the Hazard:**

According to the 2018 CA State Hazard Mitigation Plan, tsunami locations span 94 incorporated communities and 83 unincorporated areas across 20 coastal counties.

As identified on the map (below), the Humboldt State University campus is located approximately ½ mile from the tsunami inundation zone.
Extent of the Hazard:

The factors shaping the extent or severity of the hazard are a combination of geophysical forces (the amount of vertical and horizontal motion of the sea floor, the area over which it occurs, and the efficiency with which energy is transferred from the earth’s crust to the ocean water) and the geographic range of coastal development to be impacted.

More specifically, as a tsunami approaches the shore, wave run-up is the elevation above mean sea level on dry land that a tsunami reaches. A tsunami’s potential severity can be forecasted as a function of the wave’s mass along with the difference
between the wave’s run-up height and the ground elevation of the affected coastal location.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.\(^{90}\)

Given the history of tsunami occurrences in Humboldt Bay, and the range of potential impacts to Humboldt County in the future, although the campus lies outside the inundation zone, the planning committee ranks the extent of tsunami as Moderate.

History of the Hazard:

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. That said, no tsunamis have impacted CSU campus locations.

According to the National Centers for Environmental Information (NCEI), have been eight tsunamis have caused damage to ports and harbors or coastal inundation in California since 1946. The most significant events are as follows:

- In 1964, a tsunami caused by a Magnitude 9.2 earthquake offshore from Alaska resulted in 13 deaths in California and destroyed portions of downtown Crescent City.
- A 2006 tsunami (originating in the Kuril Islands region north of Japan) caused approximately $20 million in damage to Crescent City harbor.
- A 2010 tsunami (originating offshore from Chile) caused millions of dollars in damage to ports and harbors in the state.
- A tsunami in 2011 (caused by a Magnitude 9.0 earthquake offshore of Japan) killed one person at the mouth of the Klamath River and caused up to $100 million of damage to 27 ports, harbors, and marinas throughout the State. The most damage occurred in Crescent City, Santa Cruz and Moss Landing harbors and a federal disaster was declared in Del Norte, Santa Cruz, and Monterey Counties. Both Crescent City and Santa Cruz harbors sustained damage to all docks, and oil spills and water/sediment contamination that

\(\text{90}\) NOAA. About Tsunami. Retrieved on 4.29.2021 from: http://www.prh.noaa.gov/itic/library/about_tsu/faqs.html#1
resulted from sunk or damaged boats. Because recovery efforts in these two harbors took several years to complete, both harbors incurred business/economic losses that have been difficult to recapture.

91 Global Historical Tsunami Database, National Center for Environmental Information, 2019
Potential Impacts of the Hazard:

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing total devastation to coastal development.

The configuration of the coastline, the shape of the ocean floor, and the characteristics of advancing waves play important roles in the destructiveness of the waves. Bays, sounds, inlets, rivers, streams, offshore canyons, islands, and flood control channels may cause various effects that alter the level of damage. Offshore canyons can focus tsunami wave energy, and islands can filter the energy. It has been estimated that a tsunami wave entering a flood control channel could reach a mile or more inland, especially if it enters at high tide. The orientation of the coastline determines whether the waves strike head-on or are refracted from other parts of the coastline.

Although tsunami inundation mapping indicates that potential physical impacts from a tsunami wave do not exist at Humboldt State University, the campus planning committee indicates that the Aquatic Center and the campus research vessel/classroom are at risk of impact.

For Humboldt County, potential impacts include destruction of the natural environment, destruction of boats as well as other coastal development, and loss of life. Tsunamis that impact both harbors and communities also can produce free-floating debris hazards and environmental contamination from chemical spills.

Probability of Future Occurrence of the Hazard

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. If we consider historical occurrence as one data set for estimating future events, the average rate of occurrence over the past 150 years is 1 tsunami every 1.9 years. Currently, no analysis is available which differentiates this statewide probability specifically for Humboldt County, CA. Although 7 events have been recorded for the Northern California region, it is prudent to utilize the 1.9-year statewide recurrence internal for planning purposes given extreme difficulties predicting tsunami points of origin.

The rate of future occurrence may change, and may be able to make target estimates for specific locations in the future; the California State Tsunami Program is trying to refine the accuracy of the data. In doing so, the State Tsunami Program is completing a set of Probabilistic Tsunami Hazard Analysis (PTHA) maps representing risk levels from 100-year to 3000-year average return periods. Analysis using these
probabilistically based products will allow for a more common platform for comparison to other seismic and flood probabilistic analyses.92

Vulnerability to the Hazard:

With regard to CSU campus locations, direct vulnerability of assets and people to tsunami only applies to the CSU Chancellor’s Office in Long Beach, CA, as it is the only 2 campuses located in a mapped tsunami zone. (Note: Humboldt State University campus asset mapping does not identify assets within the inundation zone, although the campus committee identifies the Aquatic Center and the research vessel as located within the zone).

With regard to Humboldt State University’s vulnerabilities, the campus planning committee indicates that the California Geologic Survey datasets associated with Tsunami inundation zones will be utilized in the near future to analyze critical assets on campus that fall within zones of vulnerability. That said, the planning committee indicates that the Aquatic Center and the Coral Sea (research and classroom vessel) are located in the tsunami zone along with campus access and egress routes. In addition, according to the committee, a tsunami could create isolated islands of people due to the inundation, and no evacuation or access to hospital services. In fact, according to the 2018 State Hazard Mitigation Plan, Humboldt county’s population is among the most vulnerable to injury and life safety issues due to its close proximity to the Cascadia Subduction Zone.93

Population Vulnerability

The populations most vulnerable to the tsunami hazard are the elderly, disabled and very young who reside near beaches, low-lying coastal areas, tidal flats and river deltas that empty into ocean going waters. In the event of a local tsunami generated near the coast, little warning time would exist, so more of the population would be vulnerable, and this vulnerability may pertain to the Humboldt State University planning area. According to the campus planning committee, a tsunami could create isolated islands of people due to the inundation, and no evacuation or access to hospital services. In addition, for Humboldt County, HAZUS analysis of the inundation area indicates that a tsunami event could displace 1,441 people, with up to 96 people needing short-term shelter assistance.

Property Vulnerability

The impact of tsunami waves and the scouring associated with debris that may be carried in the water could be damaging to all structures along beaches, low-lying coastal areas, tidal flats and river deltas. The most vulnerable structures are those in

92 2018 State of California Hazard Mitigation Plan

93 2019 Humboldt County Operational Area Hazard Mitigation Plan
the front line of tsunami impact and those that are structurally unsound. According to the campus planning committee, the Aquatic Center and the Coral Sea (research and classroom vessel) are the campus’ most vulnerable assets.
Critical Facilities and Infrastructure Vulnerability

The following infrastructure is vulnerable to damage in Humboldt County, CA:

- **Water Proximate Infrastructure**—Breakwaters and piers collapse, sometimes because of scouring actions that sweep away their foundation material and sometimes because of the sheer impact of the tsunami waves.

- **Flood Control Systems**—Floodwaters can back up drainage systems, causing localized flooding. Culverts can be blocked by debris from tsunami events, also causing localized urban flooding.

- **Utility Systems**—Floodwaters can get into drinking water supplies, causing contamination. Sewer systems can be backed up, causing waste to spill into homes, neighborhoods, rivers and streams. Tsunami waves can knock down power lines and radio/cellular communication towers. Power generation facilities can be severely impacted by wave action and by inundation from floodwater.

- **Fuels**—Destruction of fueling infrastructure and related environmental and potable water contamination can occur. In Humboldt County, the Chevron terminal is located in the tsunami inundation zone on Humboldt Bay and receives most of the vehicle fuel for the county by barge.

Estimate of Potential Losses:

Estimates of potential losses specific to CSU campuses have not been conducted yet. However, for Humboldt County, the HAZUS analysis indicated that 49 percent of the county’s exposed structures (997 structures) would be impacted by the modeled scenario event with a damage estimate of $448M dollars (buildings, contents). The estimated damage value is associated with the tsunami wave only; it does not include additional damage as a result of debris battering structures or losses to from boats, bridges or utility lines. Moreover, HAZUS estimates of damage to critical facilities and infrastructure in the county show an estimated 141 facilities impacted with 66 facilities showing a light to moderate degree of damage (10% - 49% structural damage).

Vulnerability Assessment Conclusions:

According to the 2018 State of California Hazard Mitigation Plan, community exposure to tsunamis in California varies considerably—some communities may experience great losses that reflect only a small part of their community and others may experience relatively small losses that devastate them. Among the 94 incorporated communities and 83 unincorporated areas of the 20 coastal counties, the communities that are most vulnerable to injury and life safety issues exist within Del Norte and Humboldt counties due their close proximity to the Cascadia Subduction Zone.

To improve tsunami vulnerability assessments, FEMA has developed a new tsunami loss estimation module for HAZUS using existing numerical model results for tsunami...
inundation, flow depth, velocity, and force. This HAZUS module allows new capability for estimation of economic losses, and site-specific analysis of content losses, casualties, infrastructure damage, and evacuation time. The module calibrates losses based on safe zones and community preparedness levels. Such technological improvements in assessment capability can be utilized for tsunami hazard analysis and planning purposes for Humboldt State University.

Along with new probability-based tsunami maps, the HAZUS module will improve the ability to compare tsunami impacts to those of other hazards. Moreover, the probability mapping will be used for numerous applications including identifying potential tsunami hazard “zones of required investigation” under the Seismic Hazards Mapping Act and will assist state and local agencies in making land use planning decisions and will help regional and state planners understand the flood potential from tsunamis representing different risk levels. The improved analysis and data will be utilized by Humboldt State University through its partnerships with key stakeholder organizations.94

**Note:** To download the Community Exposure to Tsunami Hazards in California report visit the USGS website: [http://pubs.usgs.gov/sir/2012/5222/](http://pubs.usgs.gov/sir/2012/5222/).

**Identified Data Limitations:**

As identified in the Vulnerability Summary (above), with regard to the current planning effort, the primary data limitations for assessing the tsunami hazard for CSU campuses (Chancellor’s Office and Humboldt State University) are comprehensive asset valuations lying within the tsunami inundation zone, and the need to apply FEMA’s new probability mapping techniques and tsunami loss estimation module to the footprint of each campus. That said, CSU leadership and planning teams intends to pursue such data in the future.

94 2018 State of California Hazard Mitigation Plan
Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU Humboldt or Humboldt County is located within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While CSU Humboldt does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Humboldt is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Humboldt.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and
thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Humboldt, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

**Estimate of Potential Losses**

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

**Vulnerability Assessment Conclusions**

CSU Humboldt is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

**Identified Data Limitations**

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

---

**Wildfire**

**Description of the Hazard**

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain.97 These fires are prone to become uncontrolled, spreading through

---

97 State of California Hazard Mitigation Plan, September 2018
vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.
A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

Location of the Hazard

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. The area immediately surrounding the Humboldt State University campus is not in direct proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. However, the east side of the campus does back up into a dense forest with heavy vegetative fuels.

The Humboldt State University campus is located in Arcata at the edge of the Arcata Community Forest. The forest is densely saturated with redwood trees, ferns, and other dense vegetation. These hills surrounding the east side of the campus are largely covered in moderate to high fuel density areas. In general, areas considered to be within Local Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur immediately east of the Humboldt campus. These hills surrounding the Humboldt communities can be topographically diverse, contain heavier vegetative fuels, and often have residential development interspersed.

Figure 11-16: Wildfire Hazard Severity Zones
Extent of the Hazard

The area immediately surrounding the Humboldt State University campus is not in direct proximity to fire hazard zones designated as a High Fire Hazard Severity Zones, but the hills surrounding the east side of the campus are largely covered in moderate to high fuel density areas. Humboldt County has a long history of wildfire activity despite the fact that the campus does not have a history of wildfire activity occurring within proximity to the campus. The campus does, however, have a history of being affected by wildfire related smoke and poor air quality. Based on these conditions, the planning committee ranks the extent of the hazard on campus as **Low to Moderate**.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.
The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 11-24: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel -- especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 4: Very High Danger (VH)</td>
<td>Fires start very easily and spread at a very fast rate</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</td>
</tr>
<tr>
<td>COLOR CODE: Orange</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke.

The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Humboldt County also has a long history of wildfire activity despite the generally wet climate. Several of the historic large fires have occurred in the area of Trinidad north of the campus. Wildfires occurring in Humboldt County have resulted in hundreds of thousands of acres burned and millions of dollars in damages.

The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Humboldt State University campus has experienced multiple days of poor air quality due to fires burning in southern California mountains. The 2020 fire season in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Humboldt County. CSU Humboldt personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

Potential Impacts of the Hazard

The location of the Humboldt State University campus lies West of areas designated as High Fire Hazard Severity Zones places a potential direct threat that flame, ember, and smoke exposure from wildfire to the campus. The wet climate that normally persists in this region moderates wildfire activity, however weather conditions can shift to promote wildfire development. The potential impacts to wildfire further exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage

101 Humboldt County Operational Area Hazard Mitigation Plan 2019, January 2020
• Commercial property destruction or damage
• Loss of property contents
• Infrastructure damage
• Damaged or destroyed lifelines/supply routes
• Damaged or destroyed utilities
• Damaged or destroyed critical facilities supporting campus emergency support needs
• Loss of community economic base
• Employment losses
• Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
• Agricultural (crops and livestock) damages or destruction
• Environmental damage
• Societal and community impacts
• Damage to organizations and facilities providing support services to vulnerable populations
• Greater evacuation challenges for those most vulnerable
• Psychological impacts of impacted populations
• Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

• Dangerous levels of air pollution
• Human Health Effects
  • Similar health impacts to pets
• Air conditioning systems overwhelmed
• Greater demands on air filtration systems
• Greater demands on healthcare systems
• Reduced outdoor work productivity
• Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Humboldt County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to
areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community.

**Probability of Future Occurrence of the Hazard**

Based on the wildfire threat potential in the area on and surrounding the Humboldt State University campus, including the immediate proximity to Fire Hazard Severity Zones categorized as “Moderate”, dense vegetation/timber on hillsides east of campus, the proximity to, the historic occurrences of fires, and the typical weather conditions, the probability of wildfire related damage is considered **Unlikely**.

Based on the wildfire threat potential in the area surrounding the campus and the San Francisco East Bay region, including the volume of areas in elevated Fire Hazard Severity Zones throughout the Alameda and Contra Costa Counties, the past occurrences of wildfire generated smoke from areas beyond Alameda County, the probability of wildfire generated smoke impacts to air quality is considered **Possible**.

**Vulnerability to the Hazard**

The Humboldt State University campus is subject to a low probability direct impact from wildfire due to the campus location within a wildland-urban interface zone, in the event that offshore winds carry a hillside fire into the coastal zone. That said, the campus is not identified to reside near a designated local High Fire Hazard Severity Zone. The campus is bordered to the east and the north by hillsides and open lands containing dense vegetation. Additionally, vulnerabilities to the effects of wildfire would lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillsides and extending onto the campus or localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have significant impact to the campus. However, the typical wet weather conditions lessen the threat of fire adversely impacting the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures. Structures with vegetation and other combustibles near the structure increases the ability of fire to spread to buildings.

Some areas of particular vulnerability on the campus includes:
- Students and staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC or do not have HVAC will cause limitations in filtering of air during smoke filled days.
- Power outages or brownouts during days with high levels of smoke will limit the ability to filter the air during days with unhealthy air.
- Offshore wind events may push large fire and volumes of smoke into coastal portions of Humboldt County from interior forests.
- Students originating from outside of the Eureka area may become isolated from family if transportation routes are closed.

Access to the east using State Route 299 servicing access to Redding and interior California could become cutoff during fire incidents. Additionally, US Highway 101 both north and south of Arcata transits areas of dense forests and other vegetation that could be vulnerable to fire conditions. The university is limited by these routes for access to and from the campus. Access for supplies, equipment, and emergency services in addition to evacuation away from the campus would likely be forced to use alternative transportation methods into and out of Eureka and Arcata.

Additional concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill North Coast valleys even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. Humboldt State University students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the Humboldt State University campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.
Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $117,600,736. However due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Humboldt County, including wildfire incidents that have threatened the Humboldt State University campus and the Concord campus. The location of the Humboldt State University campus exposed to dense forests with moderate to heavy vegetative fuels along the eastern edges presents a threat of fire to the campus community and campus assets. These environments are ideal for the development of wildfire activity in the right conditions. However, the typical weather patterns for California’s North Coast provides moist air off of the ocean, regular precipitation, and fog allowing for fuel moistures to remain high. The consequences of fires in these areas would present primary and secondary.
consequences to the Humboldt State University campuses and expose vulnerabilities on the campus and to the campus community.

The topography and weather conditions of the region also allows for smoke filled air to linger in the valleys of Humboldt County with the potential for unhealthy air quality depending on wind conditions. Large fires burning from even far away locations in northern California have demonstrated to fill expansive areas with smoke filled air and travel over great distances.

Communities located within or near the Wildland Urban Interface throughout populated areas across northern California may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, and homeless students.

**Identified Data Limitations**

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail and Lightning)**

**Description of the Hazard**

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind,

---

hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

---

104 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat

106 Retrieved on 07.17.2021 from https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions
The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California.107 On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions.108 This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including Humboldt State University.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.109

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including Humboldt State) other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.110

Types of Storms in California

107 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
110 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.\textsuperscript{111} The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.\textsuperscript{112} These storms affect (in varying degrees) all CSU campuses, including Humboldt State.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{113} Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.\textsuperscript{114} Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{115} *Severe thunderstorms* are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\textsuperscript{116 117}

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.

- **Wind storm**: marked by high wind with little or no precipitation.

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.

\textsuperscript{113} Retrieved on 07.14.2021 from https://www.weather.gov/phi/ThunderstormDefinition

\textsuperscript{115} Retrieved on 07.14.2021 from https://www.noaa.gov/explainers/severe-storms

\textsuperscript{116} Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

\textsuperscript{117} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
• **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.

• **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.118

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.119 Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” 120

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including Humboldt State).

---

High Winds, Strong Winds, and Thunderstorm Winds

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\(^{121}\)

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\(^{122}\)

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\(^{123}\)

Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\(^{124}\) However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

Tornadoes

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\(^{125}\) This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most

\(^{124}\) Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/

\(^{125}\) Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/
violent tornadoes.\textsuperscript{126} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{127}

**Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.**

**Santa Ana Winds.** A type of wind hazard that is peculiar to Southern California is called a *Santa Ana Wind*. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{128} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{129} (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

\textsuperscript{126} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/

\textsuperscript{127} Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.¹³¹

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–

---

east, with the adjoining narrow coastal plain bounded by a steeply rising (to
elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner
winds because they often begin in the late afternoon or early evening, their onset is
typically associated with a rapid rise in temperature and decrease in relative humidity,
and the winds tend to blow from the north from the Santa Ynez Mountains to the
coast of Santa Barbara County, California. During the more intense Sundowner wind
events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can
even reach hurricane force (≥ 74 miles per hour) in the most extreme cases.
Temperatures over the coastal plain, and even at the coast itself, can rise significantly
above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May,
with a minimum during summer and a secondary peak in winter that often
corresponds with Santa Ana winds. In addition to causing a dramatic change from the
more typical marine-influenced local weather conditions, Sundowner wind episodes
have produced significant wind-related property and agricultural damage, as well as
conditions of extreme fire danger.132 133 134

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm
updrafts.135 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in
the upper atmosphere as ice crystals that are bounced about by high velocity updraft
winds; the ice crystals accumulate frozen droplets and fall after developing enough
weight. The size of hailstones varies and is a direct consequence of the severity and
size of the storm that produces them – the higher the temperatures at the Earth’s
surface, the greater the strength of the updrafts and the amount of time hailstones are
suspended, and therefore the greater the size of the hailstone.136

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly
heats the air in its immediate vicinity to about 50,000°F - about five times the
temperature of the surface of the sun. This compresses the surrounding air and

from a dynamically downscaled climatology: Environment and effects aloft and offshore. *Journal of
https://doi.org/10.1029/2018JD029065

creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\textsuperscript{137}

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{138} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

Location of the Hazard

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the Humboldt State campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

Extent of the Hazard

Severe weather hazards are non-spatial hazards that potentially affect all Humboldt State campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to Humboldt State reflect those of the surrounding community and County. As a result, all assets and people at Humboldt State are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Arcata area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as \textbf{MODERATE}. See each sub-hazard below for the planning committee’s sub-type extent ranking.

\textbf{Wind Hazard: Non-Rotational}

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{142}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

</tbody>
</table>

F6 Inconceivable tornado 319-379 mph These winds are very unlikely. The small area of damage they might produce would probably not be recognizable along with the mess produced by F4 and F5 wind that would surround the F6 winds. Missiles, such as cars and refrigerators would do serious secondary damage that could not be directly identified as F6 damage. If this level is ever achieved, evidence for it might only be found in some manner of ground swirl pattern, for it may never be identifiable through engineering studies.

Table below illustrates the Enhanced Fujita (EF) Scale, currently in use. Tornadoes that have occurred since February, 2007 are classified using the Enhanced Fujita Scale.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no established, objective severity scale for thunderstorms.\(^\text{147}\) \(^\text{148}\) That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light, medium, or heavy* according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\(^\text{149}\)

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;\(^\text{150}\)

---

\(^\text{147}\) Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

\(^\text{148}\) Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm

- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\(^{151}\) or

- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder). \(^{152} \)\(^{153}\)

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

**History of the Hazard**

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\(^{154}\) For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\(^{155}\) To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Humboldt County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind**: at least 114 events, or approximately 4.50 events per year
- **Strong Wind**: at least 14 events, or 0.55 events per year
- **Thunderstorm Wind**: at least 10 events, or approximately 0.39 events per year
- **All Wind Hazard events** (excluding Tornadoes): at least 132 events, or approximately 5.21 events per year (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Humboldt County, there have been at least 132 wind hazard events since 1996, excluding tornadoes. That translates to an approximate average historical frequency of occurrence of 5.21 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 138 events) and simultaneous Database searches of all severe weather hazard events (i.e., 132 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Humboldt County have actually taken place hundreds of miles away, but are erroneously recorded as events that have

occurred in the County.\textsuperscript{160} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 132 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Humboldt County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Humboldt County has experienced since 1996 have been costly. There has been 1 death, and approximately $5,736,000 in reported property damage estimates; however, there have been no reported injuries or crop damage.

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there has been 1 reported event of a tornado in Humboldt County, which translates to approximately 0.04 tornado events per year. This tornado was rated EF0 and occurred in 2018.

**Historical Tornado Hazard Losses for Humboldt County since 1996**

According to the NCEI Storm Events Database, tornado hazard event losses that Humboldt County has experienced since 1996 have been negligible. There have been no deaths, injuries, or no crop damage, and reported property damage estimates have totaled $100.\textsuperscript{161}

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 21 reported events of hail in Humboldt County, which translates to approximately 0.83 hail events per year.\textsuperscript{162} (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 22 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, hundreds of miles away.)

\textsuperscript{161} National Climatic Data Center. Storm Events Database. miles away from Humboldt County. The origin of this discrepancy is unknown at this time.)

**Historical Hail Hazard Losses for Humboldt County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Humboldt County has experienced since 1996 have been moderate. There have been 0 deaths and 1 injuries, and property damage estimates have totaled approximately $23,250; no crop damage estimates have been reported.\(^\text{163}\) (Note: The San Diego County hail event that was included erroneously in the search results for hail events in Humboldt County accounted for five (5) injuries and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there has been one (1) reported event of lightning in Humboldt County, which translates to approximately 0.04 lightning events per year.\(^\text{164}\)

**Historical Lightning Hazard Losses for Humboldt County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Humboldt County has experienced since 1996 have produced no deaths, injuries, property damage, or crop damage.\(^\text{165}\)

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

Information obtained from the NCEI Storm Events Database indicates that there have been 155 occurrences of the severe weather hazard in Humboldt County. This translates to 6.12 severe weather hazard occurrences per year.¹⁶⁶

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 162 events) and simultaneous Database searches of all severe weather hazard events (i.e., 155 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Humboldt County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.¹⁶⁷ When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 155 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Humboldt County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Humboldt County has experienced since 1996 have been costly. There has been 1 death and 1 injury, and no crop damage; property damage estimates have totaled approximately $5,759,000.¹⁶⁸ It is important to note that for all Humboldt County severe weather hazard events recorded on the Storm Events Database, the one (1) reported death and approximately 99.6% of all estimated property damages have been caused by wind hazard events alone.

**Wind Hazards Not Included in the NCEI Storm Events Database**

*Santa Ana Winds*

Santa Ana wind events occur at least twice per month from October through April.\footnote{169} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textbf{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6 days accounting for 90\% of all occurrences. The remaining 10\% are made up almost entirely of events lasting between 7 and 12 days.\footnote{170} \footnote{171}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

**Diablo Winds**

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^\text{174}\)

---

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{175}

Figure 11-20: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\textsuperscript{176}

\textbf{Sundowner Winds}

Strong sundowner wind events occur approximately \textbf{2-3 times per year}. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\textsuperscript{177}

\textbf{Historical Frequency of All Severe Weather Hazards}

Table below shows the average historical frequency of severe weather hazard events for Humboldt County since 1996.)

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within Humboldt State University campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the Humboldt State campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.
Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

According to Humboldt County Operational Area Hazard Mitigation Plan 2019, damaging wind events are considered to be medium significance, and therefore to have a moderate potential impact on the County and (by extension) the Humboldt State campus.¹⁷⁸

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

According to Humboldt County Operational Area Hazard Mitigation Plan 2019, hail hazards are considered to be of low significance, and therefore have a minimal potential impact on the County and (by extension) the Humboldt State campus.¹⁷⁹

**Lightning**

Lightning strikes the United States about 20-25 million times a year.¹⁸⁰ Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.¹⁸¹ Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.¹⁸² (Commercial claim payouts for lightning losses for the U.S. were not available.)

According to Humboldt County Operational Area Hazard Mitigation Plan 2019, lightning hazards are considered to be of low significance, and therefore have a minimal potential impact on the County and (by extension) the Humboldt State campus.\textsuperscript{183}

\textbf{Severe Weather Hazards Combined}

According to Humboldt County Operational Area Hazard Mitigation Plan 2019, important issues associated with severe weather in the planning area include the following:

- The most common direct impact from severe weather in Humboldt County is loss of power;
- Potential severe weather impacts (especially damaging winds) are greatest on older building stock in the planning area, as many of those structures are built to low code standards or none at all;
- Severe weather may also affect isolated population centers in Humboldt County disproportionately.\textsuperscript{184}

\textbf{Probability of Future Occurrence of the Hazard}

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. According to Humboldt County Operational Area Hazard Mitigation Plan 2019, although the probabilities of future occurrence of specific hazards (i.e., wind, tornado, hail, and lightning) vary greatly, the probability of any severe weather event impacting the planning area is \textbf{HIGH}.\textsuperscript{185} Also, according to the NCEI Storm Events Database, some of these same severe weather hazards have occurred in Humboldt County at least once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the Humboldt State campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the Humboldt State

campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both to Humboldt County Operational Area Hazard Mitigation Plan 2019 and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) Humboldt County and the Humboldt State campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for Humboldt State is HIGHLY LIKELY. See table below for probabilities of future occurrence for component severe weather hazards for the County and the campus.

Vulnerability to the Hazard

People, structures, and assets on the Humboldt State campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The Humboldt State campus also has
vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire Humboldt State campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within the Humboldt State campus are at risk from severe weather. There are approximately 118 buildings on the Humboldt State campus that could be damaged by wind, hail, and/or lightning hazard events. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $117,600,736 for 91 of the buildings, and are unknown for the remaining 27 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at the Humboldt State University campus varies throughout the day. As of Fall, 2019, Humboldt State had 6,983 students and 1,171 faculty and staff. All are at risk from severe weather events, with 8,154 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to the Humboldt State campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to Humboldt State.

It is evident that the Humboldt State campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
11.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the Humbolt State University campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
Table 11-34: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (housing insecurity), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (undocumented, DACA, etc.), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

1. Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
2. Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**
In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

</table>
Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Seventy percent of the students have been impacted with food issues.
- Concern is the health care system is fragile on a good day; recognize if an incident impacts beyond campus – HSU center is only the resource.
- School has the highest number of students on psychiatric drugs; resiliency and potential coping mechanism [of concern in an event]; will need medication and if can’t get the meds [of concern].
- Concern was expressed for the faculty who have opted out of RAVE system and live in geographically disbursed areas.
- Continue to have almost monthly protests regarding the death of a black student a while back.
- Maintain the emergency communications in English and Spanish; outside of that don’t have a system. Have had pushback on the RAVE alerts only going out in English. Would like to translate the EOP into the Spanish for families who don’t speak English.
- Have an annex specific to the international students in the EOP which lists the programs and regulations by law that would trigger the recall of students.
- Have relationship with the Mexican consultant
- Because LGBTQI is such a large portion of the school demographic, “it is incorporated” and a precedent is set on the campus.
- The vast majority of the student come from 8-12 hours away and don’t own cars; they utilize homebound buses to the San Francisco Bay Area and to Los Angeles.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.
<table>

</table>
**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods. Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states. Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread

---

housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.\textsuperscript{190}

\textit{Erosion}

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

\textit{Flood}

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion.\textsuperscript{191}

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with

increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionally to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural health and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, anger, sadness and grief. Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

**Hazardous Materials**

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease. Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.

**Landslides**

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied buildings which makes it a function of structural vulnerability and therefore, indirect. The degree of vulnerability to landslides by an individual considered at high risk, or even the general populations, also depends on human behavior, including many of the traditional social factors that are difficult to measure such as situational awareness, prior knowledge of hazards, and decision-making capabilities.

Landslides can result in primary lifeline failures through the loss of roads or power and communication lines. Transportation routes are often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods. Risk from landslide relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many

---

193 https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/

businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

Tsunami

TBD

Wildfire

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. 196 Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old. 197

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: 198 particulate matter, surface levels of

ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs. 199

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.200

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

12.1 University Profile

University History

CSU Long Beach was originally known as Los Angeles-Orange County State College when it began its first day of classes on September 28, 1949. The campus’s original site was temporarily in Orange County in a converted apartment building, but later moved north to its current site in the City of Long Beach (Los Angeles County). Initially, classes were only offered to junior and senior students consisting mostly of women and veterans. Course studies emphasized on Teacher Education, Business Education and Liberal Arts. The university went through various name changes up until 1972 when the university became California State University, Long Beach. ACSU Long Beach was the first CSU campus to introduce the Educational Opportunity Program (EOP). CSU Long Beach is designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the University, overseeing all academic affairs and programs of the University. The provost reports directly to the president.

University Mission

CSU Long Beach’s Mission Statement is, “To enrich students’ lives through globally informed, high impact educational experiences with superior teaching, research, creative activity, and action for the public good.”

CSU Long Beach highlights the following in ensuring success of reaching its mission and vision: Teaching and learning, accountability for the good of the public, diversity and character.

University Location

CSU Long Beach is located in Long Beach, California (population 456,154). The 322-acre campus is the third largest of the 23 California State University campuses, and one of the largest universities in the state of California by enrollment.

University Population

At CSU Long Beach, the enrollment typically exceeds 35,000 students. The university is overwhelmingly made up of undergraduate students whose average age is 22. Latino students make up 40.2% of undergrad students with Asians as the second most
populous group at 22.5% of the population. The university offers 82 different bachelor's degrees, 65 types of master's degrees, and four doctoral degrees. CSU Long Beach employs more than 8,000 individuals as faculty, staff, and student assistants.

12.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate ..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must
assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

12.3 Hazard Identification and Risk Assessment

Overview of California State University, Long Beach History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 12-1 (following).

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely**- 76%-100% that the hazard would occur annually.
- **Likely**- 50%-75% that the hazard would occur annually.
- **Possible**- 11%-49% that the hazard would occur each annually.
- **Unlikely**- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 12-1 below.)

(Source: Interviews with CSU campus staff at CSU campuses and at CSU Chancellor’s Office.)

**Descriptions of Identified Communicable Disease Hazards at CSU Long Beach**

CSU Long Beach has identified one (1) communicable disease hazard that has had the greatest impact on campus – COVID-19. The following is a brief description of the communicable disease hazard at CSU Long Beach.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called
Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.5

Location of the Hazard

Communicable diseases have the potential to affect the entire CSU Long Beach planning area equally. As a result, the communicable disease hazard can be found at the CSU Long Beach campus located in Long Beach, CA (Los Angeles County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) CSU Long Beach are at risk of exposure to the communicable disease hazard.

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students

will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For CSU – Long Beach, approximately 9% of its 38,074 enrolled students or 3,427 students reside in student housing. \(^{6,7}\)

**Extent of the Hazard**

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 12-1 describes the different BSLs and provides examples of communicable diseases that would typically fall into these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

---

The Extent of CSU Long Beach Communicable Disease Hazards Except COVID-19:

Besides COVID-19, there was no information provided on other communicable disease hazards on campus.

The Extent of CSU Long Beach COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.⁹

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 483 cases of COVID-19 at CSU Long Beach. CSU-campus-specific COVID-19 case data for CSU Long Beach can be found below.

Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19

---

case statistics for both CSU campuses and the counties where CSU campus assets are located.]

Table 12-5 shows campus-level and County-level COVID-19 Case data for CSU Long Beach. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

---

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the CSU – Long Beach campus. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU – Long Beach students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU – Long Beach) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 12-7: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are</td>
</tr>
</tbody>
</table>

often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)

<table>
<thead>
<tr>
<th>RG3</th>
<th>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 12-9 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 12-8: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG I</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
</tbody>
</table>

---

<table>
<thead>
<tr>
<th>RG 2</th>
<th>Chicken Pox</th>
<th>Hepatitis A, B, C</th>
<th>Lyme disease</th>
<th>Salmonella</th>
<th>Mumps</th>
<th>Measles</th>
<th>Malaria</th>
<th>Scrapie</th>
<th>Dengue Fever</th>
<th>HIV</th>
</tr>
</thead>
</table>

These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.

<table>
<thead>
<tr>
<th>RG 3</th>
<th>Anthrax</th>
<th>West Nile Virus</th>
<th>SARS Virus (Including COVID-19)</th>
<th>Tuberculosis</th>
<th>Typhus</th>
<th>Yellow Fever</th>
<th>Hantaviruses</th>
<th>Avian Flu</th>
</tr>
</thead>
</table>

These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

<table>
<thead>
<tr>
<th>RG 4</th>
<th>H5N1 (Bird Flu)</th>
<th>Dengue Hemorrhagic Fever</th>
<th>Marburg Virus</th>
<th>Ebola Virus</th>
<th>Smallpox</th>
<th>Lassa Fever</th>
<th>Crimean-Congo Hemorrhagic Fever</th>
</tr>
</thead>
</table>

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar
decontamination procedures to eliminate the possibility of an accidental release.

**Probability of Future Occurrences of the Hazard**

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.

Table 12-10 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

<table>
<thead>
<tr>
<th>Table 12-9: Likelihood of Future Hazard Occurrence</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Likelihood</strong></td>
</tr>
<tr>
<td>Highly Likely</td>
</tr>
<tr>
<td>Likely</td>
</tr>
<tr>
<td>Possible</td>
</tr>
<tr>
<td>Unlikely</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s system-wide probability ranking (below) reflects the ranking at the individual CSU campus level unless noted otherwise.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the CSU – Long Beach campus.
CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, CSU – Long Beach had 38,074 students along with additional faculty and staff.)\(^{16,17}\) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree in the current COVID-19 pandemic on the CSU – Long Beach campus.

**Estimate of Potential Losses**

**COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities**

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU – Long Beach) are at risk of developing an extreme incidence of COVID-19 and may become “super-spreaders” for adjacent communities.\(^{18}\) The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due

\(^{16}\) The California State University. *Enrollment.* Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. Several CSU campuses saw refund losses surpass $10 million. (See Figure 12-2 below for economic impacts to CSU – Long Beach).

Figure 12-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table CD.10) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems. (See Table CD.11 below for the “10% outbreak scenario” projections both for the CSU – Long Beach campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system, including
CSU – Long Beach. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Dam and Levee Failure**

**Description of the Hazard**

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to
furnish flood protection from seasonal high water or divert the flow of water. Most
levees in California are intended to withstand peak water levels generated by heavy
precipitation or rapid snowmelt in a watershed. Other levees are designed to
withstand fluctuating water levels on a continuous basis such as those in the
California Delta exposed to tidal influences. Levees routinely extend for lengthy
distances immediately protecting communities. Levees can be found throughout the
state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from over topplings to small uncontrolled discharge to
catastrophic failure. Areas downstream of the failure will be subject to inundation
dependent on the volume of water released. These levee failures are also typically the
result of structural age, damage to the structure caused by earthquake or flooding,
slumping, seepage underneath the levee, high velocity flows eroding the levee,
inadequate capacity, inadequate maintenance, improper construction materials, or
extreme inflow of water into the system. Flood damage resulting from levee failures
potentially will result in economic losses, environmental damage, destruction of
agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including
the extent of the collapse or breach, the volume of water behind the structure, and the
nature of the exposed downstream features. This unpredictable flooding presents a
threat to life and property in addition to critical infrastructure. Lifelines and supply
routes will likely be damaged or made impassible by flood erosion or standing water.
Water quality and health concerns would likely be cascading effects of dam or levee
failures.

Location of the Hazard

Los Angeles County is home to a variety of flood control facilities and levee systems
mostly along the base of the various mountains and hills throughout the county.
Levees have been constructed along numerous flood control channels providing
community protection. The CSU Long Beach campus is in general proximity to dams
upstream along the Los Angeles River and Rio Hondo systems in addition to flood
control channels lined with levees.

There are a number of dam facilities along the base of the San Gabriel Mountains and along the river systems extending from the mountains. The larger facilities include the San Gabriel Dam, Morris Dam, Santa Fe Dam, and Whittier Narrows. Each of these facilities regulate water that flow along the San Gabriel River and Rio Hondo systems. The CSU Long Beach campus lies outside of dam inundation zones for these facilities.
The San Gabriel River drains the San Gabriel Mountains and much of the eastern Los Angeles Basin south towards Long Beach. A number of flood control systems feed into the San Gabriel River. The length of the San Gabriel River from between Downey and Norwalk to the outlet into the ocean is a large concrete lined channel. The channel is located almost ¾ mile east of the CSU Long Beach campus and is separated from the campus by additional flood control channels.

The Los Cerritos Channel is a flood control and drainage channel ¼ mile east of the campus that drains much of the urban water collection of the South Bay communities. The channel feeds into the Pacific Ocean at the Alamitos Bay with drainage from South Bay communities such as North Long Beach, Lakewood, and Bellflower. The Los Cerritos Channel is a concrete lined flood control channel fed by additional channels above the campus.

The Bouton Creek channel is an additional flood control channel that crosses through the campus from the northwest to the southeast. The 2-mile channel feeds into the Los Cerritos Channel and ultimately into the Pacific Ocean at Alamitos Bay. The
channel drains the Signal Hill and eastern Long Beach areas. The center of the Long Beach campus has been built over the channel.

Figure 12-5: Dams and Levees with Critical Assets

extent of the hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.
Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

The CSU Long Beach campus lies outside of the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the CSU Long Beach campus is expected to remain out of the inundation area. The inundation area is expected to spread water in areas upstream from the campus and remain within the flood control channels in proximity to the campus. However, there are multiple transportation corridors that lie within the dam inundation zones that could compromise transportation routes and areas the campus community reside or work. Based on these conditions, the planning committee ranks the extent of the hazard on campus as Low.

**Extent – Levee Failure**

Levees are used along numerous flood control channels and other waterways including the Los Angeles River, San Gabriel River, and Los Cerritos Channel. The CSU Long Beach campus lies outside of the levee flood protected area. In the event any of these channels were flowing at elevated levels and a failure of a levee were to occur, while the campus would not experience direct impacts, the community surrounding the campus would likely experience flood related damages. This specific hazard could alter the ability of the campus to maintain operations. Based on these conditions, the planning committee ranks the extent of the levee failure hazard as Low.

**History of the Hazard**

---

There are no records of dam or levee failures in areas that present a threat to the CSU Long Beach campus. The City of Long Beach has not identified a history of dam or levee failures elsewhere in the city. Los Angeles County has experienced the following dam failures:

Potential Impacts of the Hazard

Dam Failure Impacts – While the campus is not within a dam inundation zone, transportation routes, critical infrastructure, and campus community members may reside within inundation zones. Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

Levee Failure Impacts – A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

Probability of Future Occurrence of the Hazard
The location of the CSU Long Beach campus downstream from the Santa Fe Springs Dam and other flood control facilities along the San Gabriel River and Coyote Creek demonstrates that the potential exists for future dam or levee related secondary impacts. However, the distance from the river channel provides an additional mitigating factor, meaning that the City of Long Beach including the CSU Long Beach campus resides outside of known dam inundation zones. Los Angeles River 39 levee system resides immediately to the east of the campus, however, the campus is outside of the levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on historical experience and occurrences, and based on consistent dam and levee monitoring and maintenance protocols, the probability of future occurrence for both dam and levee failures is Unlikely.

Vulnerability to the Hazard

Given High Priority dam monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. In addition, the campus does not lie within an inundation zone. As such, the campus is not considered to be vulnerable on a daily basis. However, in the unlikely event of a catastrophic failure, the effects of flooding from compromised dams and levees on campus would most likely be limited to indirect or secondary effects in terms of disruption to regional transportation networks and services, and the amount of time to respond to the needs of the campus community prior to inundation will be limited.

It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in the vulnerability of displaced individuals and households. The lack of flood insurance will cause extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the CSU Long Beach campus will vary depending on the degree of breach or structural failure and when the failure were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in low probability, region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.
Some areas of particular vulnerability to dam failure from the Fullerton Reservoir on the campus includes:

- Water inundation of the Children’s Center.
- Water inundation of the campus corporation yard
- Water inundation of the University Police Department
- Chemicals, bottled gases, radioactive materials, biological materials, and explosive compounds are stored in campus science labs, chemical storage facilities, Facilities Maintenance Shops, and Engineering Labs
- Inundation of the Tri-Gen Powerplant
- Residential halls are located on east side of campus likely outside of inundation zone but will require evacuation and mass care and shelter assistance needs
- State College Blvd and Yorba Linda Blvd potential for flood inundation limiting access to and from the campus.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to dam or levee failure are $453,426,848. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU Long Beach.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the CSU Long Beach campus, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. The consequences of a dam failure would
generate catastrophic results to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.
**Drought**

**Hazard Description**

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
Socioeconomic drought refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - Long Beach) versus water usage for wildfire abatement or natural resource protection.

Location of the Hazard

Drought conditions have been identified in Los Angeles County where CSU – Long Beach is located, though the campus committee reports no drought history or locations specific to the campus, as the campus has no “Ag” programs or resources. That said, drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.27

(Insert reference to drought map locations in the plan)

Extent of the Hazard

Given the historical occurrence of severe drought impacts throughout the county surrounding the planning area and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies.

In addition, although drought affects the entire CSU system wide planning area, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction.

Also, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been

---

measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. These same effects, though not identified on campus, will remain issues of concern over the long term.

For CSU – Long Beach, the extent of the hazard is Low (corresponding to D0-D1 on the extent scale below). However, the campus planning committee recognizes that the potential for more severe conditions exists and is tied to regional water resource vulnerabilities.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous across the state. Los Angeles county (which includes the CSU - Long Beach footprint) has experienced 5 or more periods of drought from 2000-2021 including a severe statewide event from 2012-2019.

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply.

The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.\textsuperscript{30}

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 12-7: Periods of Drought in State of California, 2001 – 2021\textsuperscript{31}

Although no drought events or impacts have been reported that are specific to the campus, given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state including Los Angeles County where the CSU - Long Beach campus planning area:

\textbf{2012 – 2017} – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, ‘it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report

calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent. 32

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the CSU - Long Beach campus planning area is a reduction in water availability for the municipal area tied to the campus. Other potential impacts include damage to trees and other natural features (See Tree Mortality below).

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such.33 However, the wildfire hazard is analyzed separately in this plan. See wildfire section towards the end of this plan.

In reviewing the occurrences of drought for Los Angeles County, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2014-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - Long Beach, the broad geographic extent of the impact makes it fairly likely that tree mortality occurred to some degree on the campus. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition,

drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.34

At present, drought related damage to campus buildings and infrastructure at CSU - Long Beach has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - Long Beach is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Long Beach. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Probability of Future Occurrence of the Hazard

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that CSU - Long Beach lies within a drought

---

impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Long Beach campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - Long Beach planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires. 36

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average.

Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir. 37

**Vulnerability of Populations**

Drought vulnerabilities include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerability measures apply to the students, faculty and staff of the CSU – Long Beach campus.

**Property Vulnerability**

Drought vulnerabilities include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerability measures apply to the properties of the CSU - Long Beach campus.

**Natural Environment Vulnerability**

Natural environment vulnerabilities are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

Drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In

addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for CSU - Long Beach’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.
Estimate of Potential Losses

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the city and county of Los Angeles, and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

Vulnerability Assessment Conclusions

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

Identified Data Limitations

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
**Earthquake**

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.
**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU Long Beach is located in the southern portion of the Los Angeles Basin. In general, fault systems surround and traverse through Los Angeles and Orange Counties including the area of CSU Long Beach. Throughout the basin the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

In addition to the main campus, the CSU Long Beach satellite facilities liquefaction site status is included. The CSU Long Beach, Lancaster University Center in Lancaster, CA does not reside within a liquefaction zone. The Southern California Marine Institute located on Terminal Island in San Pedro has been identified as being located on a liquefaction zone.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 50-55 miles northeast of the CSU Long Beach campus. In addition to the San Andreas Fault, Los Angeles County is home to or near additional fault systems with the potential to generate strong ground shaking. The Newport-Inglewood Fault traverses south to north paralleling the Orange County coastline extending within ¾ mile of CSU Long Beach from the southwest corner of the campus. The Palos Verdes Fault crosses the Palos Verdes Peninsula approximately 11 miles east of the campus. The 40-mile-long Compton Fault parallels the Palos Verdes Fault in a southeast to northwest direction 9 miles east of the CSU Long Beach campus. The Whittier-Elsinore Fault extends from the eastern base of the Santa Ana Mountains and western base of the Puente Hills 15 miles to the northeast of the campus. There are numerous additional faults in the area on all sides of the campus.
The CSU Long Beach campus reside outside of areas designated to be liquefaction zones for the portions of the campus south of the Bouton Creek channel. Campus facilities north of the Bouton Creel channel are located within the liquefaction zone. Additionally, substantial areas of the community surrounding the campus to the north, east, and south do reside within the liquefaction zone. This also includes major transportation corridors including Interstate 405, Interstate 605, State Route 22, State Route 1, Bellflower Blvd., and Atherton Street. The liquefaction zone includes multiple campus facilities.

Figure 12-9: Liquefaction Zones in Proximity to CSU Long Beach

---

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale (below) is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for
example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 12-10: Earthquake Magnitude and Equivalent Energy Release

![Graph Showing Earthquake Magnitudes and Equivalent Energy Release](https://www.usgs.gov/media/images/graph-showing-earthquake-magnitudes-and-equivalent-energy-release)

Based on the history of earthquake occurrences in Los Angeles County, including a near catastrophic event in Long Beach, and the presence of 9 fault systems.

---

throughout the county, and ongoing predicted severe events statewide, the planning committee ranks the extent of the hazard as **Moderate**.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Los Angeles County also has a long history of earthquake activity. The entire area of Los Angeles County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The most recent significant earthquake to occur in immediate proximity to Long Beach was in July of 1933. The earthquake occurred on the Newport-Inglewood Fault off of the coast of Newport Beach. The earthquake was felt throughout Southern California and resulted in damages in multiple counties. Long Beach experienced multiple fires, 127 water main breaks, and liquefaction was experienced along the waterfront. Regionally, including Long Beach, 120 people were killed, 5,000 injured, 20,000 homes were damaged, and 75% of schools were destroyed\(^{41}\).

\(^{41}\) City of Long Beach Hazard Mitigation Plan, February 28, 2017

\(^{42}\) 2019 County of Los Angeles All-Hazards Mitigation Plan, 2019
Other earthquakes of significance include, the more recent January 17, 1994 Northridge Earthquake estimated a Magnitude 7.7 earthquake struck at 4:52 am. The earthquake occurred on the White Wolf Fault in hills east of Bakersfield resulting in numerous surface ruptures. Twelve people were killed in the county and several hundred were injured. The shaking was strong enough to cave in railroad tunnels near Tehachapi, 40 miles east of Bakersfield. Railroad lines were warped, buildings collapsed in Bakersfield, and there was widespread underground utility and pipeline damage. Shaking was felt from Sacramento to San Diego.

The October 1, 1987 Whittier Narrows Earthquake shook a large part of southern California. The earthquake caused $358 million in damages, especially in the Alhambra, Pasadena, and Whittier areas. The earthquake resulted in extensive infrastructure damages, multiple injuries, and 8 fatalities. The earthquake was provided a federal disaster declaration (DR-799).

The February 9, 1971 Magnitude 6.5 San Fernando Earthquake struck the San Fernando Valley in Los Angeles just after 6am. The intense shaking caused the collapse of freeway overpasses, hospitals, and other infrastructure. It damaged thousands of homes and businesses, a reservoir, and critical infrastructure. 65 people were killed and 2,000 more were injured. The shaking was felt for 300 miles including in Las Vegas, Nevada. The earthquake was provided a federal disaster declaration (DR-299).

The Fort Tejon Earthquake, a Magnitude 7.9 earthquake, struck in 1857 along the San Andreas fault just north of Los Angeles County. The earthquake was able to shift the Kern River upstream and run four feet over its banks. Structural damage was limited as the area was sparsely populated at the time. The Fort Tejon Earthquake remains one of the greatest earthquakes ever recorded in the United States producing a surface rupture extending over 220 miles.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Los Angeles area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Long Beach could cause injuries or fatalities to members of the campus community or
support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Long Beach could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Los Angeles County and Orange County region limiting immediate assistance that the campus may normally expect.

- Local impacts to CSU Long Beach campus caused by an earthquake could include:
  - Damage to nearby refineries and petrol-chemical plants
  - Damage and secondary fires to industrial buildings to the east of campus
  - Potential hazardous material releases on and off campus
  - Potential liquefaction-based effects to most areas of the campus and large areas of the surrounding cities
  - Infrastructure to freeway system
  - Structural damage to bridges over waterways and flood control channels
  - Structural damage to flood control systems
  - Potential isolation of campus from community
  - Potential isolation among on-campus residents
  - Structural damage to San Gabriel River and Los Cerritos Channel levees
  - Structural damage to campus academic and support buildings
  - Structural damage to residence halls resulting in displaced student populations
  - Structural damage to nearby residences
  - Community members arriving on campus for refuge from damaged homes
  - Damaged university communications, computer systems, and networks
  - Considerable stress and fear among community
  - Closure or reduction of service to campus operations
  - Reduction of campus revenue

**Probability of Future Occurrence of the Hazard**

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops
Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Los Angeles County fault systems surrounding Long Beach is included in the following table.

Table 12-20: Table xx Major Potentially Active Faults in Proximity to CSU Long Beach

Based on the earthquake shaking potential in the Los Angeles Basin, the proximity to the above listed fault systems, the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of Long Beach places the campus in a busy commercial and industrial areas that is heavily populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus. The north-western corner of the campus is designated as a liquefaction zone and may be impacted by the levee systems to the north and west if full and compromised.

---

43 2019 County of Los Angeles All-Hazards Mitigation Plan, 2019

The known fault systems generating the threat to Long Beach generally surround the city and some cross into the city including near to the CSU Long Beach campus. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment would be vulnerable to damages from building, seismic shaking, secondary fires, and secondary building floods from broken pipes.

Some areas of particular vulnerability on the campus includes:

- Numerous multi-level buildings including a 9-story building and 6 story parking structure.
- Temporary office structures include FO4 and FO5
- Chemicals, bottled gases, radioactive materials, biological materials, and explosive compounds are stored in campus science labs, chemical storage facilities, Facilities Maintenance Shops, and Engineering Labs
- Two elevated water towers located to the southwest of campus south and the West Turn Around
- The campus childcare center is located in the Family and Consumer Sciences Building close to the water towers
- The pool chemical storage facility is located next to the swimming pool north of the staff parking area behind the Kinesiology Building
- Underground gas lines are distributed across the campus feeding kitchens in the University Student Union, Food Services dining areas, and the Residence Halls dining areas
- Underground gas lines additionally feed laboratories in Peterson Hall, Microbiology, Molecular Science, and Family and Consumer Science buildings.

Elements of the vulnerability to a major earthquake on the CSU Long Beach campus will vary depending on when the earthquake were to strike. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.
The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. As the CSU Long Beach campus is areas exposed to levee facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $453,426,848.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater Los Angeles region and the CSU Long Beach campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU Long Beach campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding Long Beach, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Los Angeles region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

Vulnerabilities will be seen in the physical infrastructure on the campus and the human population of the campus community. Campus infrastructure is vulnerable to severe shaking particularly in areas where the ground is loose or susceptible to liquefaction. Specifically older buildings, masonry constructed buildings, and other structures susceptible to shaking related damage are the most vulnerable. Communication systems, computer networks, and other electronic systems may be vulnerable when overwhelmed by increased demand during emergencies or by shaking related damages. The people of the campus community are vulnerable to effects of intense shaking in the form of injuries from falling debris, exposure to secondary floods or fires, loss of employment, extreme disaster induced stress, and loss of access to critical services or social contacts.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks
continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.
Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Erosion**

*Description of the Hazard*

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.”

Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

*Location of the Hazard*

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While coastal erosion can happen in any storm, it is more likely during El Nino events, which occur every 5-7 years. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across those areas of the campus with erosion-prone characteristics.

Other incidents of erosion, such as occurs around buildings, is relatively non-spatial and can occur in any locations with conducive soil structure and a source of movement, such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover.

*Extent of the Hazard*

Erosion is occurring on the Pacific coastline west of CSU Long Beach. While there is no published scale of severity or extent for this geologic hazard on the CSU Long

---

Beach campus, erosion may occur if conditions are favorable and the erosion process goes unmitigated. However, given no historical occurrence of erosion on campus, the planning committee ranks the extent of this hazard as Low.

History of the Hazard

Erosion mitigation is occurring along Long Beach’s coastline, including sand pumping and slope stabilization projects. However, there are no recorded incidents of erosion on the CSU Long Beach campus.

Potential Impacts of the Hazard

Coastal erosion can result in severe impacts to local infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, and its occurrence along the nearby coastline, the probability of future occurrence is Likely over the long term.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Long Beach infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion.

In the wider Long Beach community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality. As such, CSU leadership may consider a more in-depth analysis of erosion vulnerabilities on campus in the future.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.
Vulnerability Assessment Conclusions

While the ability to predict future erosion on the CSU Long Beach campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

Extreme Temperatures (Includes Extreme Cold and Extreme Heat)

Description of the Hazard

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.46

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.47 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feels” hotter. The combination of temperature and humidity is known as the heat index.48

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.49 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and

48 Ibid.

outdoor workers, low-income households, and individuals with certain chronic medical conditions.\(^{50}\)

**Location of the Hazard**

Extreme heat events are a non-spatial hazard, and may occur throughout the Cal State Long Beach campus.

**Extent of the Hazard**

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the high 70s to mid-80s in Long Beach. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at the Long Beach Daugherty Airport was 111° F on September 27, 2010.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria.\(^{51}\) In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 12-11 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.

Given no extreme heat events in Long Beach in over a decade, only 5 recorded events overall, and that the City of Long Beach Hazard Mitigation Plan does not consider

---

excessive heat to be a considerable hazard\textsuperscript{53}, the planning committee ranks the extent of the hazard as Low.

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been five excessive heat events in Los Angeles County since 2007. These events were grouped together as part of the same heat waves.

**August 30, 2007; September 1, 2007; September 3, 2007:** A combination of high temperatures and high humidity produced an extreme heat event across Southern California. Heat index values ranged from 105° to 112° F. There were eight deaths attributable to this excessive heat event.

**June 20-21, 2008:** During this large-scale heat wave that impacted much of the state, afternoon high temperatures climbed as high as 114° F. The heat resulted in several power outages due to excessive electrical use.

The NCDC database also lists 85 additional times that the recorded temperature at the Long Beach Daugherty Airport has reached 100° F or greater between 1980 and 2018.

Potential Impacts of the Hazard

Cal State Long Beach may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

There have been no extreme heat events in Long Beach in over a decade. Therefore, using the scale provided, it is only possible that the hazard will occur annually.

\textsuperscript{53} Hazard Mitigation Plan, City of Long Beach. *Table of Contents.* Print. Retrieved 01.27.21 from: https://www.longbeach.gov › longbeach-hazard-mitigation-plan
Notably, the Hazard Mitigation Plan prepared by the City of Long Beach does not consider excessive heat to be a considerable hazard.\textsuperscript{54}

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.\textsuperscript{55} This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Cal State Long Beach is aware of the potential for extreme heat events. The campus sponsors training for all new hires so they are aware of the California State laws and federal regulations guiding safe working conditions in the heat. The campus does not sponsor cooling centers during heat waves because all buildings are air-conditioned, but Cal State Long Beach has faced local power outages that have forced the shutdown of individual buildings or facilities.

Therefore, even though this is a hazard that the campus does not face regularly, the campus has ample familiarity with excessive heat in order to handle the risks and vulnerabilities of hot weather.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at Cal State Long Beach is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three

\textsuperscript{54} Hazard Mitigation Plan, City of Long Beach. \textit{Table of Contents}. Print. Retrieved 01.27.21 from: https://www.longbeach.gov › longbeach-hazard-mitigation-plan

\textsuperscript{55} Centers for Disease Control and Prevention. \textit{Heat and People with Chronic Medical Conditions}. Retrieved 03.13.21 from https://www.cdc.gov/disasters/extremeheat/medical.html
degrees on average over the last century, with less rainfall. This may lead to stronger and longer-lasting heat events, drought, and an increased risk of wildfires.56

**Identified Data Limitations**

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

**Flood**

**Description of the Hazard**

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing

Flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Floods can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.
Atmospheric River

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Location of the Hazard

Long Beach is at the south end of the South Bay communities and at the terminus is the Los Angeles and San Gabriel Rivers. The area around Long Beach is relatively flat and sits between the Palos Verdes Hills and hills further to the east. These include the Puente and Chino Hills which provide a potential for developing water run-off during heavy precipitation events. The rivers that drain into the Pacific Ocean serve as drainage basins for the watersheds of the Santa Monica and San Gabriel Mountains. There are a number of flood retention basins and flood control channels along the base of these hills that drain towards Long Beach to protect Los Angeles and Orange County communities. The area surrounding the campus is a developed suburban environment predominately consisting of residential and commercial land uses.

57 National Oceanic and Atmospheric Administration, “What are atmospheric rivers?”, https://www.noaa.gov/stories/what-are-atmospheric-rivers
The CSU Long Beach campus is located 2 miles north of the Pacific Ocean, ¾ mile from the San Gabriel River, ½ mile from the Los Cerritos Channel, and sees the Bouton Creek channel transit through the center of campus. The San Gabriel River watershed receives the majority of its water from snowfall from the San Gabriel Mountains. The San Gabriel River and Los Cerritos Channel contribute to a direct flood hazard to the campus and would compromise access routes to the campus if failed. The campus north of the Bouton Creek in the CSU Long Beach campus sits within a Special Flood Hazard Area (SFHA) Zone X: Area with Reduced Flood Risk Due to Levee designation on the Flood Insurance Rate Map. The campus south of the Bouton Creek channel is removed from a flood risk designation and classified as Zone X: Area of Minimal Flood Hazard. Access routes and critical infrastructure to the east and north are located in Zone X: Area with Reduced Flood Risk Due to Levee while those access routes and critical infrastructure west and south of the campus are designated Zone X: Area of Minimal Flood Hazard.

Extent of the Hazard
The CSU Long Beach campus resides in a minimally threatened flood zone. However, flood events are still possible and isolated heavy precipitation events can still pose localized flooding hazards. In fact, there is a historic record of isolated urban or street flood events on the campus that have generated damages. This specific hazard could substantially alter the ability of the campus to maintain operations. In addition, 6 Federally Declared events have occurred in LA County during the 25-year period from 1996-2021. Based on these facts, the planning committee ranks the extent of the hazard on campus as Moderate.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 12-23: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>

<td>Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.</td>
</tr>
<tr>
<td>X (unshaded)</td>
<td>Undetermined</td>
<td>Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.</td>
</tr>
</tbody>
</table>

History of the Hazard

Flooding in Long Beach and the broader Los Angeles County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the CSU Long Beach campus. Also, there is a historic record of isolated urban or street flood events on the campus that have generated damages.

58 2019 County of Los Angeles All-Hazard Mitigation Plan, 2019
Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Inability for campus operations to resume
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues
Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

Floods can occur at any time but are most common in the Los Angeles area with winter storms saturated with subtropical moisture. Flooding occurs on average every 6.1 years from heavy precipitation that could generate potential 50- or 100-year floods in the CSU Long Beach area. The CSU Long Beach campus is located within both a Zone X Special Flood Hazard Area (Area with Reduced Flood Risk Due to Levee) and Zone X (Area of Minimal Flood Hazard), as well as in close proximity to the Bouton Creek channel. There are specific buildings and low lying areas of the campus that have a greater risk for isolated flooding. There is a historic record of isolated urban or street flood events on the campus that have generated damages further providing a demonstration of potential flood activity.

As such, the planning committee ranks the probability of future occurrence for flooding as Possible.

Vulnerability to the Hazard

The CSU Long Beach campus is subject to the effects of flooding resulting primarily from excessive precipitation and isolated strong storms. There is a more remote potential for severe flooding and damage on campus and surrounding residential and commercial areas of Long Beach due to overflow or damage to flood control systems. The flood control channels and drainage systems that surround the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the CSU Long Beach campus will vary depending on the severity of flooding and when the flood were to occur and the location of people and assets in low lying, flood-prone areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community may become trapped on campus depending on the level of flooding occurring on surface streets. However, in rare, region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

CSU Long Beach is in proximity to a variety of industrial and commercial facilities in the surrounding communities. When these facilities are inundated with flood water,
the potential for chemical release exists presenting possible exposures to individuals from the campus community. These facilities additionally line many of the primary access routes in and out of the campus.

Some campus buildings and infrastructure, especially those in low lying areas, would be vulnerable to low probability, large-scale flooding if it reaches the university. Campus utilities and communication capabilities could be impacted by flood waters rendering them disabled. A flood covering a large portion of the city could affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls, if located in low lying, flood-prone areas, may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. Flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $453,426,848. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. The campus’ proximity to Bouton Creek, Los Cerritos Channel, and San Gabriel River adds an additional risk and degree of vulnerability for the campus.

The potential for flooding generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures, while unlikely, has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations
Lack of comprehensive historic flooding occurrences, missing campus structural replacement costs, and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.
**Hazardous Materials**

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”59 Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

---

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within all surrounding communities. The planning committee indicates that chemicals are located in the science lab, but otherwise no known hazardous materials are present on campus. At larger scales (beyond the campus planning area) extensive hazardous materials and infrastructure are located throughout the city of Long Beach and throughout Los Angeles County, and reflect different types, configurations and scales dispersed across these geographic areas.

---

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

However, for the CSU – Long Beach planning committee, although only small chemical spills have taken place on campus, and hazardous materials are limited to chemicals in the science building, an extensive array of gas pipelines, rail lines, fuel tanks, chemical industries and hazardous waste sites are located close to the campus. Based on these factors, it is prudent to rank the extent of the hazard for the CSU – Long Beach campus as High, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes - In recent years, Long Beach has experienced several chemical fires and oil refinery explosions resulting in injuries and deaths.

Moreover, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

For more details on specific hazmat events, please refer to the local, county and/or multi-jurisdictional hazard mitigation plans where CSU campuses are located at:

According to the campus planning committee, a small chemical spill took place in the science building on the CSU – Long Beach campus about 3 years ago, though none recently and none required evacuation. However, the City and Port of Long Beach have experienced numerous deadly hazardous materials explosions.

Potential Impact of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – Long Beach campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

Potential Impact of the Hazard (Natechs)

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Long Beach) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.67

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the CSU – Long Beach campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence originating on campus is Low to Moderate - the campus has experienced small-scale chemical spills. However, extensive hazardous materials and infrastructure are close to the campus, and several deadly chemical explosions have taken place in recent years. Therefore, the probability of occurrence near the campus is High or Likely. Moreover, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a high degree of risk to the CSU – Long Beach campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: chemicals are present in the science lab, and a high degree of hazardous waste sites, chemical sites, rail lines, gas pipelines, fuel tanks and more are close to the campus. Gases, fuels, chemicals or hazardous waste, if spilled, released or exploded, could lead to injury and death, and/or severely impact human health as well as campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Long Beach leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

**Estimate of Potential Losses**

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

**Vulnerability Assessment Conclusions**

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Long Beach) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the City of Long Beach and Los Angeles County hazard mitigation plans and Cal OES’ records of hazardous material spills, that such events occur with great frequency in Long Beach and to varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Long Beach campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.
Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – Long Beach planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.

**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure.68 These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow.69 These landslides may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 12-15 below. Based on the Figure below, the CSU-Long Beach campus is not connected to, or close to areas susceptible to landslide.

---

Extent of the Hazard

In Los Angeles County, landslides are more likely to occur in the steep slopes outside of the metropolitan area and along the coastline. The San Gabriel mountains, both steep and erosive, contain steeply walled canyons above areas with high population density. When heavy rain occurs, there is significant potential for floods and landslides throughout the County, and the indirect impacts of landslides in the region may cover a larger geographical extent. Based on the campus’ distance from the landslide hazard zone, and no history of occurrence on or near the campus, the planning committee ranks the extent of the landslide hazard for the campus as Low.

---

History of the Hazard

FEMA has declared thirteen major disasters involving landslides, mudslides, debris flows, or mud flows in Los Angeles County since 1978. NOAA has recorded five debris flow events in the County since 2004, most of which occurred in the areas directly surrounding metropolitan Los Angeles. The 2018, the Southern California Mudflows damaged 40 to 45 homes in Sun Valley and caused a vehicle to strike a natural gas pipeline, which began to leak. No landslide events on or near the campus have been recorded.

Potential Impacts of the Hazard

The CSU Long Beach campus may experience secondary impacts such as the disruption of campus operations as a result of landslides in the region. Students, faculty, and staff living elsewhere in Los Angeles may be more directly impacted. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure in the region. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are also often triggered by other natural hazards, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in the San Gabriel Mountains and therefore are likely to occur in the future. However, given the location of the campus far removed from landslide susceptibility zones, and no historical occurrence of landslides on or near campus, the planning committee ranks the probability of the landslide hazard on the campus as Unlikely.

Vulnerability to the Hazard

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Moreover, any
population proximal to a landslide when it occurs is vulnerable to its impacts. However, other than the temporary disruption of transportation routes or campus operations, the CSU-Long Beach campus does not exhibit these vulnerabilities.

Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Bakersfield.

Vulnerability Assessment Conclusions

Landslides could impact the campus primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the CSU Bakersfield campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.13

Power Outage

Description of the Hazard

Long Beach, California is Los Angeles County’s second largest city. Approximately 20 miles south of downtown Los Angeles, Long Beach is home to some of the world’s largest ports, oil fields, tourist attractions and CSU Long Beach. The city spans approximately an area of 51 square miles.

Long Beach, like other metropolitan cities, would experience disruptions in most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An Interruption in the supply or distribution of these commodities can leave highly populated areas, like Long Beach, with basic services, such as electricity or sanitation with an inability to manage these issues. Power outage interruptions can be cascading effects from other disaster events or incidents, such as the result of major windstorm, floods, or an earthquake. Due to the City of Long Beach’s location and that of the University, Public Safety Power Shut offs due to wildfires are not a factor the campus regularly experiences.
In the event of a power outage at Cal State Long Beach, a power outage event can disrupt day-to-day operations at the campus, like in-person classes, special events, impede or limit digital communications, interrupt telephonic or radio communications, make elevators, entry ways and other devices malfunction or inoperable. Additionally, impacts can occur to the surrounding campus community by forcing temporary closures of local restaurants and other types of vendors. For the thousands of Cal State Long Beach student residents in on-campus housing, a loss of power would affect students residing in off campus housing in the area, as well.

Additionally, a severe outage to Los Angeles County or the City of Long Beach would also directly affect the campus and the community creating social, economic, and potential health and safety impacts. Traffic flow around and to the campus may experience significant challenges due to a combination everyday traffic and large trucks transporting goods in and out of the ports of Long Beach and Los Angeles.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

- The four types of **intentional** disruptions:
  - Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
  - Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
  - Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
  - Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a circumscribed area, it has the potential to affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO) which is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities. CAISO is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are as follows:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Although only 1 recorded outage has taken place on campus, they occur from time to time in the City of Long Beach. Therefore, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard

The City of Long Beach has experienced power outages over time. Their electric utility provider, Southern California Edison (SCE) has experienced outages, which have affected the residents of Long Beach over the years. Major power outages impacting the City of Long Beach in recent years have affected a large number of residents as seen below:
• July 18, 2015: The City of Long Beach experienced a power outage for three days, in what is known as the worst blackout since the 1950’s. Most residents and businesses experienced the large power outage. The power outage was due to an underground electrical fire. A manhole cover flew into the air, with pressurized flames and smoke shooting into the air along with it. The fire led to 4,800 homes and businesses losing power.

• February 20, 2021: A loss of power occurred in South Long Beach due to arcing wires touching down on some parked vehicles. Southern California Edison crews repaired the issue over several hours to de-energize the power cables. The power outage affected approximately 3,000 Long Beach residents.

The campus has also experienced power outages:

• October 20, 2020: SCE notified students that a scheduled power outage would occur over night from 8pm to 6am on October 20 and 21. Due to the Coronavirus pandemic, many classes transitioned to a remote environment and for those students who needed to remain in resident dorms, eating schedules and connectivity issues were an impact the community had to manage. Dining hours were reduced, and internet and electricity resources were unavailable.

Potential Impacts of the Hazard

Instructors, campus residents, staff and administration rely on electricity for basic operations. During a widespread power failure, it may take anywhere from several hours to days to restore operations if a significant event occurs. Electrical power is most likely the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-
degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

Probability of Future Occurrence of the Hazard

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. Long Beach and LA county experience such outages. As such, the probability ranking for the Long Beach area is Likely; although the campus has recorded fewer events than the surrounding area, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

Vulnerability to the Hazard

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

Although the campus has specific power outage protocols in place, an outage can impact the operations of the university depending on the severity of the outage. During daytime hours, the University may remain open and business and instructional operations will remain on-going at the maximum extent possible. It will be expected that the areas surrounding the campus, including streetlights, will have also experienced a blackout.

During dark hours, staff, students and faculty are to remain on campus for fifteen minutes in the event that power returns. In the event that the power returns business and instructional operations will resume. If power is not restored, instruction will stop, and business operations will stop for the remainder of the evening.
Classes and university operations and projects utilizing hazardous materials are required to immediately stop to avoid additional hazards.

**Estimate of Potential Losses**

The data provided by Cal State Long Beach State does not report any value for potential losses due to power outage.

**Vulnerability Assessment Conclusions**

The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Channel Islands. Safety and operations protocols center on the following “direct impact” set of concerns:

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and, to maintain a safe campus environment and visibility during nighttime hours. The vulnerable population (especially students with physical disabilities) may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors, and locks and lights may impede on a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

**Identified Data Limitations**

Cal State Long Beach did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
Tsunami

Description of the Hazard

A tsunami is a wave triggered by any form of land displacement along the edge or bottom of an ocean or lake. Land displacement can be in the form of submarine landslides or submarine dip-slip faults. These types of faults cause ruptures that result in seafloor uplift or down-drop. This mass movement translates to a tsunami or gravity wave within the overlying water at the surface.

Tsunamis travel radially outward from the area of initiation. The size of a tsunami is proportional to the mass that moved to generate the tsunami. As a tsunami approaches the shore and the depth of the water column decreases, the energy in the wave pushes the wave crest above the water surface resulting in a larger wave height. Wave runup is the elevation above mean sea level on dry land that a tsunami reaches. Run-up is what causes inundation of coastal areas that are below the run-up height.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement, both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing severe damage to coastal development. At the shoreline, tsunamis may take the form of a fast-rising tide, a cresting wave, or a bore (a large, turbulent wall-like wave). The bore phenomenon resembles a step-like change in the water level that advances rapidly (from 10 to 60 miles per hour). The first wave is usually followed by several larger and more destructive waves.

Location of the Hazard:

CSU – Long Beach is located proximate to the tsunami inundation zone. See tsunami map (below) with campus location identified within the zone. Also, see the tsunami inundation zone map for the City of Long Beach for the larger geographic range of the coastal inundation area.

Note: According to the campus planning committee, the university leases a building that it believes lies in the tsunami zone. Although not mapped, the university may verify and map the property’s location in the future, only with the permission of the owner.
Figure 12-15: Tsunami Inundation Area at CSU Long Beach
Extent of the Hazard:

The factors shaping the extent or severity of the hazard are a combination of geophysical forces (the amount of vertical and horizontal motion of the sea floor, the area over which it occurs, and the efficiency with which energy is transferred from the earth’s crust to the ocean water) and the geographic range of coastal development to be impacted.

More specifically, as a tsunami approaches the shore, wave run-up is the elevation above mean sea level on dry land that a tsunami reaches. A tsunami’s potential severity can be forecasted as a function of the wave’s mass along with the difference between the wave’s run-up height and the ground elevation of the affected coastal location.
There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height. Given the location of the campus proximate to the tsunami inundation zone, and the potential impacts to campus operations and local transportation/evacuation routes, the campus planning committee ranks the extent of the hazard as Moderate.

History of the Hazard:

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. That said, no tsunamis have impacted CSU campus locations.

According to the National Centers for Environmental Information (NCEI), have been eight tsunamis have caused damage to ports and harbors or coastal inundation in California since 1946. The most significant events are as follows:

- In 1964, a tsunami caused by a Magnitude 9.2 earthquake offshore from Alaska resulted in 13 deaths in California and destroyed portions of downtown Crescent City.
- A 2006 tsunami (originating in the Kuril Islands region north of Japan) caused approximately $20 million in damage to Crescent City harbor.
- A 2010 tsunami (originating offshore from Chile) caused millions of dollars in damage to ports and harbors in the state.
- A tsunami in 2011 (caused by a Magnitude 9.0 earthquake offshore of Japan) killed one person at the mouth of the Klamath River and caused up to $100 million of damage to 27 ports, harbors, and marinas throughout the State. The most damage occurred in Crescent City, Santa Cruz and Moss Landing harbors and a federal disaster was declared in Del Norte, Santa Cruz, and Monterey Counties. Both Crescent City and Santa Cruz harbors sustained damage to all docks, and oil spills and water/sediment contamination that resulted from sunk or damaged boats. Because recovery efforts in these two harbors took several years to complete, both harbors incurred business/economic losses that have been difficult to recapture.

In addition, the Worldwide Tsunami Database, www.ngdc.noaa.gov) provides information on tsunami run-up levels and earthquake magnitude factors. Although data for the most recent events is not available, additional (earlier) tsunami events are recorded.

* The City of Long Beach has not been impacted by a tsunami previously, according to the 2016 City of Long Beach Hazard Mitigation Plan. That said, a tsunami event is recorded (above) in 1933, though the run-up height of 0.1 meters or 4 inches, so it is understandable that no event was observed on the ground.

Potential Impacts of the Hazard:

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing total devastation to coastal development.

The configuration of the coastline, the shape of the ocean floor, and the characteristics of advancing waves play important roles in the destructiveness of the waves. Bays, sounds, inlets, rivers, streams, offshore canyons, islands, and flood control channels
may cause various effects that alter the level of damage. Offshore canyons can focus tsunami wave energy, and islands can filter the energy. It has been estimated that a tsunami wave entering a flood control channel could reach a mile or more inland, especially if it enters at high tide. The orientation of the coastline determines whether the waves strike head-on or are refracted from other parts of the coastline.

Potential impacts to the campus of the CSU – Chancellor’s Office in Long Beach include destruction of campus buildings and infrastructure, destruction of the natural environment, destruction of boats and coastal development, and loss of life in the area surrounding the campus. Tsunamis that impact both harbors and communities also can produce free-floating debris hazards and environmental contamination from chemical spills.

Probability of Future Occurrence of the Hazard:

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years.72 If we consider historical occurrence as one data set for estimating future events, the average rate of occurrence over the past 150 years is 1 tsunami every 1.9 years statewide. Currently, no analysis is available which differentiates this statewide probability specifically for Long Beach, CA. Although 1 event is registered for Long Beach and 6 events for the Southern CA region, it is prudent to utilize the 1.9-year recurrence interval for planning purposes given extreme difficulties predicting tsunami points of origin.

That said, the rate of future occurrence may change and may be able to make target estimates for specific locations in the future; the California State Tsunami Program is trying to refine the accuracy of the data. In doing so, the State Tsunami Program is completing a set of Probabilistic Tsunami Hazard Analysis (PTHA) maps representing risk levels from 100-year to 3000-year average return periods. Analysis using these probabilistically based products will allow for a more common platform for comparison to other seismic and flood probabilistic analyses. 73

Vulnerability to the Hazard:

With regard to CSU campus locations, direct vulnerability of assets and people to tsunami only applies to the CSU Chancellor’s Office in Long Beach, CA, as this is the only campus located in a mapped tsunami zone. (Note: See section X for the Chancellor’s Office campus assets/tsunami zone mapping).

73 2018 State of California Hazard Mitigation Plan
Regarding the vulnerabilities for the CSU - Long Beach campus location, while it is not modeled to be at risk of direct impact from tsunami inundation, it lies adjacent to the inundation zone to the west and south of its facilities. The zone’s greatest vulnerabilities are properties located near Oceanfront and the Port of Long Beach. Tsunami “maximum run-up” projections were modeled by the University of Southern California and distributed by the California Office of Emergency Services for the purposes of identifying tsunami hazards. The tsunami model was the result of a combination of inundation modeling and onsite surveys and determined the maximum projected inundation levels from tsunamis along the entire coast of Los Angeles County. Given that inundation modeling changes over time and is not able to predict real world outcomes with 100% accuracy, it is conceivable that an actual worst case tsunami event could impact the campus.

The maximum run-up for is approximately 42 feet. This means that based on the worst-case scenario tsunami, the displaced water level would be approximately 42 feet above the normal tide for that day and time. As such, given that the campus is located close to the inundation zone, students, staff and visitors may be unable to evacuate with proper lead-time.  

Vulnerability of Populations

The populations most vulnerable to the tsunami hazard are the elderly, disabled and very young who reside near beaches, low-lying coastal areas, tidal flats and river deltas that empty into ocean going waters. In the event of a local tsunami generated near the coast, little warning time would exist, so more of the population would be vulnerable. While direct impacts to campus staff and students are not projected, the city’s evacuation capability could be exceeded by a worst-case event.

Property Vulnerability

While campus property is not directly vulnerable, the impact of tsunami waves and the scouring associated with debris that may be carried in the water could be damaging to surrounding structures. The most vulnerable structures are those in the front line of tsunami impact and those that are structurally unsound. According to the 2018 State of California Hazard Mitigation Plan, Long Beach exhibits among the state’s highest number and density of businesses located in the tsunami zone.

Critical Facilities and Infrastructure Vulnerabilities

While CSU – Long Beach is not projected to sustain direct impacts to infrastructure, the following (proximate) infrastructure is vulnerable to direct damage which could affect the campus:

74 2016 City of Long Beach Hazard Mitigation Plan.
Water Proximate Infrastructure—Breakwaters and piers collapse, sometimes because of scouring actions that sweep away their foundation material and sometimes because of the sheer impact of the tsunami waves.

Flood Control Systems—Floodwaters can back up drainage systems, causing localized flooding. Culverts can be blocked by debris from tsunami events, also causing localized urban flooding.

Utility Systems—Floodwaters can get into drinking water supplies, causing contamination. Sewer systems can be backed up, causing waste to spill into homes, neighborhoods, rivers and streams. Tsunami waves can knock down power lines and radio/cellular communication towers. Power generation facilities can be severely impacted by wave action and by inundation from floodwater.

Fuels—Destruction of fueling infrastructure and related environmental and potable water contamination can occur. In Humboldt County, the Chevron terminal is located in the tsunami inundation zone on Humboldt Bay and receives most of the vehicle fuel for the county by barge.

Estimate of Potential Losses

Estimates of potential losses specific to CSU campuses have not been conducted yet. In addition, no estimated loss data is currently available for the City of Long Beach, although the local mitigation plan indicates concern for losses related to fires from damaged ships in ports or from ruptured coastal oil storage tanks and refinery facilities in the port area. That said, according to the State plan, technological improvements have been made in the ability to estimate losses from tsunami impacts which can be brought to bear on loss estimation for CSU campuses in the future.

Vulnerability Assessment Conclusions:

According to the 2018 State of California Hazard Mitigation Plan, community exposure to tsunamis in California varies considerably—some communities may experience great losses that reflect only a small part of their community and others may experience relatively small losses that devastate them. Among the 94 incorporated communities and 83 unincorporated areas of the 20 coastal counties, the communities of Alameda, Oakland, Long Beach, Los Angeles, Huntington Beach, and San Diego have the highest number of people and businesses in the tsunami inundation zone.75

For improving assessments of vulnerability, FEMA has developed a new tsunami loss estimation module for HAZUS using existing numerical model results for tsunami inundation, flow depth, velocity, and force. This HAZUS module allows new capability for estimation of economic losses, and site-specific analysis of content losses,

casualties, infrastructure damage, and evacuation time. The module calibrates losses based on safe zones and community preparedness levels. Such technological improvements in assessment capability can be utilized for tsunami hazard analysis and planning purposes for the CSU Chancellor’s Office.

Along with new probability-based tsunami maps, the HAZUS module will improve the ability to compare tsunami impacts to those of other hazards. Moreover, the probability mapping will be used for numerous applications including identifying potential tsunami hazard “zones of required investigation” under the Seismic Hazards Mapping Act and will assist state and local agencies in making land use planning decisions. They will also help regional and state planners understand the flood potential from tsunamis representing different risk levels. The improved analysis and data will be utilized by the SU Chancellor’s Office through its partnerships with key stakeholder organizations.76

Identified Data Limitations:

As identified in the vulnerability conclusions (above), with regard to the current planning effort, the primary data limitations for assessing the tsunami hazard for CSU campuses mostly pertain to a complete set of valuations for the assets of the Chancellor’s Office campus lying within the tsunami inundation zone. In addition, the CSU system-wide effort would benefit from FEMA’s new probability mapping techniques and tsunami loss estimation module to the footprint of those campuses proximate to the inundation zone to ensure that the current “not at risk of direct impact” to staff, students and physical assets still holds true. That said, CSU leadership and planning teams intends to pursue such data in the future.

---

**Volcano (Associated Air Quality)**

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”77

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within

76 2018 State of California Hazard Mitigation Plan

it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU Long Beach or Los Angeles County is located within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While CSU Long Beach does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Long Beach is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Long Beach.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Long Beach, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.
Vulnerability Assessment Conclusions

CSU Long Beach is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.

Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and

volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially influence the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire's ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience a decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. CSU Long Beach and the City of Long Beach are located in the southern end of the Los Angeles Basin along the coast. This area near the university is dominated by urban and suburban communities with limited direct exposures to wildland fire. CSU Long Beach has extensive residential neighborhoods surrounding the campus. Industrial land uses are located to the southeast of the campus.
The CSU Long Beach campus is located in the eastern side of Long Beach near the border of Orange County. The campus is 12 miles east of the closest area designated as having a high fire hazard in the Palos Verdes Peninsula where there is a mix of residential neighborhoods and hillsides with moderate vegetative fuels. The campus is not located next to areas with a fire hazard potential making direct impacts by fire on the campus unlikely.

However, the CSU Long Beach campus is surrounded by mountains and extensive areas of fire hazards further away. Surrounding the Los Angeles Basin are large mountain ranges including the San Gabriel, San Bernardino, and Santa Ana Mountains. These mountain ranges host three national forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the basin in the right wind conditions. The geography of the Los Angeles Basin and San Gabriel, San Fernando, and San Bernardino valleys creates a topography that captures air pollutants including smoke within surrounding mountains and the development of inversion layers. The CSU Long Beach campus is located in a region in which wildfire smoke can saturate the air around the campus.

Figure 12-17: Fire Hazard Severity Zones\textsuperscript{80}

Extent of the Hazard

While the threat of fire directly affecting the campus is minimal, the direct effect of fire generated smoke has occurred on campus and might occur in the future. Fires are likely to occur in areas close enough to the campus that generate substantial amounts of smoke that could envelop the campus in the right atmospheric conditions. Fires that are large enough to generate volumes of smoke to cover great distances have the potential to affect the air quality of the Los Angeles County area including the campus. This will especially be the case in weather conditions creating strong offshore winds. The potential for this impact has been demonstrated during the summers of 2018, 2019, and 2020 as fires burned across the state and spread smoke over vast distances. Fires burning outside of the Los Angeles County region have the potential to distribute smoke onto the CSU Long Beach campus.

Given that the area immediately surrounding the CSU Long Beach campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones, and the campus does not have a history of wildfire activity occurring within proximity to
the campus, it nevertheless has experienced impacts to air quality from smoke. Therefore, the planning committee ranks the extent of the hazard as Low to **Moderate**.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 12-27: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CLASS 4: Very High Danger (VH)</th>
<th>Fires start very easily and spread at a very fast rate. Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Orange</td>
<td></td>
</tr>
<tr>
<td>CLASS 5: Extreme (E)</td>
<td>Fire situation is explosive and can result in extensive property damage. Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</td>
</tr>
<tr>
<td>COLOR CODE: Red</td>
<td></td>
</tr>
</tbody>
</table>

Agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke.

The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Los Angeles County also has a long history of wildfire activity primarily in the foothills and mountains of the San Gabriel and Santa Monica Mountains. Wildfires occurring in Los Angeles County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damages.

The area immediately surrounding the CSU Long Beach campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Long Beach campus has experienced multiple days of poor air quality due to fires burning in Los Angeles, Orange, Riverside, and San Bernardino Counties. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Los Angeles County. CSU Long Beach personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

**Potential Impacts of the Hazard**

The location of the CSU Long Beach campus surrounded by areas of urban development removed from areas with a fire hazard places a minimal direct threat from wildfire to the campus. The potential impacts to wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable

\textsuperscript{84} 2019 Los Angeles County All-Hazards Mitigation Plan, 2019
Psychological impacts of impacted populations
Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Los Angeles County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community.

Probability of Future Occurrence of the Hazard

Based on the minimal wildfire threat potential in the area surrounding the CSU Long Beach campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered Unlikely.

Based on the wildfire threat potential in the area surrounding Southern California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered Possible.

Vulnerability to the Hazard

The CSU Long Beach campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban/suburban area of Long Beach. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of Long Beach. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.
Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

Some areas of particular vulnerability on the campus include:

- Students and staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC or do not have HVAC will cause limitations in filtering of air during smoke filled days
- Power outages or brownouts during days with high levels of smoke will limit shelter in place options during heat events in summer.
- Santa Ana wind events may push large volumes of smoke into the Los Angeles Basin

The greater concerns regarding vulnerabilities to wildfire on CSU Long Beach are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Los Angeles Basin even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Long Beach students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire which will vary depending on when the air quality were to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.
Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $453,426,848. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher. However, the location of the campus in an urban/suburban setting removed from hazard prone areas makes wildfire related damages unlikely.

*Buildings with no value defined are also included in the respective Zones they are found in.

The CSU Long Beach Lancaster University Center in Lancaster, CA is included in the non-burnable category. This location is within the developed desert community of Lancaster. The Southern California Marine Institute, located in San Pedro is included in the non-burnable category. This facility is located on Terminal Island in the Port of Los Angeles.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Los Angeles County; however, wildfire incidents do not pose a direct risk to the CSU Long Beach campus. The location of the CSU Long Beach campus surrounded by densely developed
residential, commercial, and industrial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The students, faculty, and staff of CSU Long Beach who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the campus. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.

Additionally, the topography of Southern California surrounded by mountains allows for smoke filled air to linger in the valleys of the Los Angeles Basin with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains generating tremendous quantities of smoke present tremendous health related vulnerabilities to members of the campus community. The campus community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

**Identified Data Limitations**

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, and Lightning)**

**Description of the Hazard**

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, heat, rainfall)
hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

87 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat

89 Retrieved on 07.17.2021 from https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions
The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU Long Beach.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU Long Beach), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its

90 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
92 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
93 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
strength, characteristics, and the scale of the resulting damage. The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California. These storms affect (in varying degrees) all CSU campuses, including CSU Long Beach.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. *Severe thunderstorms* are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.

- **Wind storm**: marked by high wind with little or no precipitation.
• **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\(^{103}\)

• **Coastal storm**: Large wind-driven waves and/or storm surge that strike the coastal zone.\(^{104}\)

• **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\(^{105}\)

• **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\(^{106}\)

---

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

---

Wind Hazards

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure. Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU Long Beach).

High Winds, Strong Winds, and Thunderstorm Winds

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.
Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\(^{112}\) However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

**Tornadoes**

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\(^{113}\) This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\(^{114}\) On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\(^{115}\)

**Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.**

*Santa Ana Winds.* A type of wind hazard that is peculiar to Southern California is called a *Santa Ana Wind.* Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\(^{116}\) They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\(^{117}\) (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

Figure 12-19: What Drives a Santa Ana Wind?\textsuperscript{118}

\textit{Diablo Winds}. The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.\textsuperscript{119}

\textit{Sundowner Winds}. Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique

\textsuperscript{118} Retrieved on 07.14.2021 from https://twitter.com/nwslosangeles/status/933049473034579968

\textsuperscript{119} Retrieved on 07.13.2021 from https://www.fireweather.org/diablo-winds
topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force (39-54 miles per hour) or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.120 121 122

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.123 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.124

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and

creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\textsuperscript{125}

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{126} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the CSU Long Beach campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all CSU Long Beach campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU Long Beach reflect those of the surrounding community and County. As a result, all assets and people at CSU Long Beach are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Long Beach area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **M od er ate**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

---

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as MODERATE.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^\text{130}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

\(^{130}\) Retrieved on 07.19.2021 from https://www.weather.gov/tae/ef_scale
It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 12-31: Fujita Tornado Scale (Pre-February 2007) ¹³¹

</tr>
</tbody>
</table>

These winds are very unlikely. The small area of damage they might produce would probably not be recognizable along with the mess produced by F4 and F5 wind that would surround the F6 winds. Missiles, such as cars and refrigerators would do serious secondary damage that could not be directly identified as F6 damage. If this level is ever achieved, evidence for it might only be found in some manner of ground swirl pattern, for it may never be identifiable through engineering studies.

Table below illustrates the Enhanced Fujita (EF) Scale, currently in use. Tornadoes that have occurred since February, 2007 are classified using the Enhanced Fujita Scale.

Table 12-32: Enhanced Fujita Scale (February 2007 and Later) ¹³²

<td>166-200 mph</td>
<td>Devastating damage. Well-constructed houses and whole frame houses completely leveled; cars thrown and small missiles generated.</td>
</tr>
<tr>
<td>EF5</td>
<td>&gt;200 mph</td>
<td>Incredible damage. Strong frame houses leveled off foundations and swept away; automobile-sized missiles fly through the air in excess of 100 m (107 yd); high-rise buildings have significant structural deformation; incredible phenomena will occur.</td>
</tr>
</tbody>
</table>

Based on the extent ranking factors identified (above), the planning committee ranks the extent of tornados as **LOW**.

**Extent: Hail**

The National Oceanic and Atmospheric Administration and the Tornado and Storm Research Organization (TORRO) have combined efforts to create the Hailstorm Intensity Scale. Table below provides details of this scale.
Table 12-33: Combined NOAA/TORRO Hailstorm Intensity Scale\textsuperscript{133}

<table>
<thead>
<tr>
<th>Size Code</th>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no established, objective severity scale for thunderstorms. That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light, medium, or heavy* according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;

135 Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms

136 Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm

• **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\(^\text{139}\) or

• **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\(^\text{140} \, \text{141}\)

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

**History of the Hazard**

Severe weather hazards have been an annual occurrence in Los Angeles County and on the CSU Long Beach campus. Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\(^\text{142}\) For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\(^\text{143}\) To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some

degree experiences the severe weather events reported for the surrounding community and County.

Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Los Angeles County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind:** at least 387 events, or approximately 15.28 events per year
- **Strong Wind:** at least 3 events, or 0.12 events per year
- **Thunderstorm Wind:** at least 43 events, or approximately 1.70 events per year
- **All Wind Hazard events** (excluding Tornadoes): at least 427 events, or approximately 16.86 events per year. (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Los Angeles County, there have been at least 427 wind hazard events since 1996, excluding tornadoes.¹⁵⁰ That translates to an approximate average historical frequency of occurrence of 16.86 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 433 events) and simultaneous Database searches of all severe weather hazard events (i.e., 427 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Los Angeles County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.¹⁵¹ When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 427 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Los Angeles County has experienced since 1996 have been costly. There have been 2 deaths and 4 injuries reported from wind hazard events (excluding tornadoes) in Los Angeles County; no property or crop damage has been reported.¹⁵²

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 12 reported events of tornadoes in Los Angeles County, which translates to approximately 0.47 tornado events per year.¹⁵³

¹⁵⁰ National Climatic Data Center. Storm Events Database. The vast majority of tornado reports in Los Angeles County since 1996 have been of tornadoes with a severity rating of F0/EF0. Only one (1) of the 12 reported tornadoes has been rated F1/EF1 or higher (it was an F1 tornado that occurred in 1998); that translates to approximately 0.04 events of F1/EF1 tornadoes have occurred per year in Los Angeles County.\(^{154}\)

**Historical Tornado Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Los Angeles County has experienced since 1996 have been minimal. There have been no deaths, or property or crop damage reported; however, 1 injury has been reported.\(^{155}\) (Note: The F1/EF1 tornado that occurred in Los Angeles County in 1998 caused the one (1) reported injury.)

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 18 reported events of hail in Los Angeles County, which translates to approximately 0.71 hail events per year.\(^{156}\) (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 19 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, over 100 miles away from Los Angeles County. The origin of this discrepancy is unknown at this time.)

**Historical Hail Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Los Angeles County has experienced since 1996 have been costly. While there have been 0 deaths and 0 injuries, property damage estimates have totaled approximately $3,500,000; no crop damage estimates have been reported; the property damage estimate reflects

searches of all severe weather hazard events (i.e., 466 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as "Thunderstorm Wind" or "Hail" that are reported for Los Angeles County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County. When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 466 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Los Angeles County has experienced since 1996 have been costly. There have been 4 deaths and 18 injuries, and property damage estimates have totaled approximately $3,500,000; no crop damage has been reported. It *is important to note that for all Los Angeles County severe weather hazard events recorded on the Storm Events Database, lightning has accounted for half of the deaths, and 13 out of 14 (92.9%) injuries reported. However, hail has accounted for all estimated property damages.*

**Wind Hazards Not Included in the NCEI Storm Events Database**

**Santa Ana Winds**

Santa Ana wind events occur at least twice per month from October through April. From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

---

Diablo Winds

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\textsuperscript{167}

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\(^{168}\)

Figure 12-21: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\(^{169}\)

### Sundowner Winds

Strong sundowner wind events occur approximately **2-3 times per year.** These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\(^{170}\)

### Historical Frequency of All Severe Weather Hazards

Table below shows the average historical frequency of severe weather hazard events for Los Angeles County since 1996.)

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within CSU Long Beach campus areas are at risk from the effects of severe weather.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU Long Beach campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.
Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

According to the 2017 City of Long Beach Hazard Mitigation Plan Local Hazard, the “Windstorm” hazard (i.e., high wind, including tornado, that is primarily caused by Santa Ana winds) is a hazard that poses enough of a “significant” threat to the city that it could result in the declaration of a local disaster. On a scale of 1 (lowest) to 4 (highest), it is rated as a 2.95 (out of 4) in terms of significance. As a result, the wind hazard is considered to be of medium to high significance, and therefore to have a moderate to high potential impact on both the city and (by extension) the CSU Long Beach campus.\textsuperscript{171}

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

According to the 2017 City of Long Beach Hazard Mitigation Plan Local Hazard, hail hazards are not considered to be significant hazards, and are therefore not included in the hazards profiled by the Plan. As a result, the hail hazard is deemed to have low significance, and therefore to have a minimal potential impact on both the city and (by extension) the CSU Long Beach campus.\textsuperscript{172}

**Lightning**

Lightning strikes the United States about 20-25 million times a year.\textsuperscript{173} Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.\textsuperscript{174} Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately

$15,334,600,000, or $958,412,500 worth of payouts per year.\(^{175}\) (Commercial claim payouts for lightning losses for the U.S. were not available.)

According to the 2017 City of Long Beach Hazard Mitigation Plan Local Hazard, lightning hazards are not considered to be significant hazards, and are therefore are not included in the hazards profiled by the Plan. As a result, the lightning hail hazard is deemed to have low significance, and therefore have a minimal potential impact on both the city and (by extension) the CSU Long Beach campus.\(^{176}\)

Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The 2017 City of Long Beach Hazard Mitigation Plan states that the probability of “Windstorm” events (i.e., high wind events – including tornadoes – caused primarily by Santa Ana winds) occurring in Long Beach is “Highly Likely;” that is, they are frequent events with a well-documented history of occurrence and an annual probability of greater than 1 in 10 (>10%).\(^{177}\) Also, according to the NCEI Storm Events Database, severe weather wind hazard events (excluding tornadoes) have occurred in Los Angeles County 427 times since 1996, or an average of 16.86 times per year.\(^{178}\) Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Long Beach campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU Long Beach campus reflect those of the surrounding community and County identified in Table 12-XX below.

Based on the data available from both the 2017 City of Long Beach Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU Long Beach campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU Long Beach is HIGHLY LIKELY. See Table 12-XX for probabilities of

Vulnerability to the Hazard

People, structures, and assets on the CSU Long Beach campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The CSU Long Beach campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire CSU Long Beach campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.
All structures within the CSU Long Beach campus are at risk from severe weather. There are approximately 119 buildings on the main campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $453,426,848 for 87 of the buildings, and unknown for the remaining 32 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is not currently available, though CSU leadership may pursue such data in the future.

The population at the CSU Long Beach campus varies throughout the day. As of Fall, 2019, CSU Long Beach had 38,074 students and 4,004 faculty and staff. All are at risk from severe weather events, with 42,078 being directly vulnerable in this scenario.

**Vulnerability Assessment Conclusions**

Severe weather presents a variety of hazards to the CSU Long Beach campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU Long Beach.

It is evident that the CSU Long Beach campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

**Identified Data Limitations**

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI)

---

collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
12.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Long Beach campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
### Question

Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning?

- Students experiencing homelessness
- Populations who are housing and food insecure
- Populations with access and functional needs

Which population groups are most difficult to reach in an event?

- International students
- Commuter students and employees
- Populations with access and functional needs

Which population groups have little/limited support networks if impacted by an event?

N/A

### Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as *Very High, High, Medium, Low*
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as *Yes, No, In Progress, NA*
In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- EOP is reviewed by the health center before finalized.
- CARES referrals: anyone can refer to CARES, [referrals] gone through the roof; absolute increase, seeing referrals coming in.
- Access Center, head of the dept, is involved with the committees and plans and review everything; separate plans on issues such as; have an ongoing partnership
- Town hall and press conference having ASL interpreters.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

Drought

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\footnote{News Deeply. “Study finds two groups hardest hit by California’s drought.” Accessed January 8, 2020. https://www.newsdeeply.com/water/community/2017/01/25/study-finds-two-groups-hardest-hit-by-californias-drought.} Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\footnote{NASA. “Earth’s Freshwater Future: Extremes of Flood and Drought.” June 13, 2019. https://climate.nasa.gov/news/2881/earths-freshwater-future-extremes-of-flood-and-drought/.} Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

Earthquake

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community
services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.\textsuperscript{183}

\textit{Erosion}

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

\textit{Extreme Temps}

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

\textit{Heat}

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile,

plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 184

**Flood**

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior

and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. 185

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural health and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, anger, sadness and grief. 186 Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues.

Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

**Hazardous Materials**

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease.\(^{187}\) Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.\(^{188}\)

\(^{187}\) [https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/](https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/)

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Sea Level Rise**

TBD

**Tsunami**

TBD

**Hazard Mitigation and Emergency Management Planning**

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

13.1 University Profile

University History

California State University, Los Angeles (Cal State LA) is located on the site of one of California’s 36 original adobes, built in 1779 by Franciscan missionaries and destroyed by fire in 1908. These lands were once known as Rancho Rosa Castilla, given to Juan Batista Batz, a Basque rancher from Northern Spain who settled here in the 1850s.

Founded by an Act of the California legislature in 1947, Los Angeles State College opened for classes on the campus of L.A. City College. In 1949, Los Angeles State College became Los Angeles State College of Applied Arts & Sciences, with 2,187 students. Six (6) years later, in 1955, groundbreaking began for a new Los Angeles State College of Applied Arts & Sciences campus, and in 1958, the first classes were held on the newly built (and current) campus site. In 1964, Los Angeles State College was officially renamed California State College at Los Angeles and became part of the California State College system. The college then received University status and was officially renamed California State University, Los Angeles (Cal State LA) in 1972. Notable achievements include the establishment of the nation’s first Chicano Studies program in 1968, as well as the development of Cal State LA’s Charter College of Education, the first such college of higher education in the nation in 1993. Today, Cal State LA is designated as both a Hispanic-Serving Institution (HSI) and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The Executive Committee operates in an advisory capacity for the university president. The Cabinet is comprised of senior leaders on campus who provide advice to the president in addressing strategic and operational issues and in pursuing new initiatives.

University Mission

“Cal State LA transforms lives and fosters thriving communities across greater Los Angeles. We cultivate and amplify our students’ unique talents, diverse life experiences, and intellect through engaged teaching, learning, scholarship, research, and public service that support their overall success, well-being, and the greater good.”

Cal State LA highlights twelve core values fundamental to their success by prioritizing the students of Cal State LA, pushing the limits of their goals and challenges, engaging the
public through service, valuing diversity, equity and inclusion, engaging the student population at Cal State LA, engaged learning, pursuing academic distinction, creating and growing a community of scholars, practicing a culture of excellence, transparency, mutual respect within the CAL STATE LA community, and inspiring academic freedom.

University Location

Cal State LA’s main campus is located in the University Hills district of Los Angeles, CA, about five (5) miles east of Downtown Los Angeles. A satellite campus, Cal State LA Downtown, is located in Downtown Los Angeles.

University Population

Cal State LA has a total enrollment of 28,531 students. The full-time enrollment at Cal State LA is 23,319 students and the part-time enrollment is 5,212. This means that 81.7% of students enrolled at Cal State LA are enrolled full-time.

The enrolled student population at Cal State LA, both undergraduate and graduate, is 63% Hispanic or Latino, 13.6% Asian, 7.19% White, 3.76% Black or African American, 1.82% Two or More Races, 0.109% American Indian or Alaska Native, and 0.0841% Native Hawaiian or Other Pacific Islanders.

The most popular Bachelor’s Degree concentrations at Cal State LA are General Business Administration & Management, Sociology, and General Psychology. Cal State LA is predominantly a commuter campus.

13.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.
Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

13.3 Hazard Identification and Risk Assessment

Overview of California State University, Los Angeles History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-
To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 13-1 (following).

Future Occurrence Probability

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- Highly Likely- 76%-100% that the hazard would occur annually.
- Likely- 50%-75% that the hazard would occur annually.
- Possible- 11%-49% that the hazard would occur each annually.
- Unlikely- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent.¹ They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions.² The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.³

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)⁴

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 13-2 below.)

**Descriptions of Identified Communicable Disease Hazards at Cal State LA**

Cal State LA has identified three (3) communicable disease hazards that have had the greatest impact on campus – COVID-19, E. coli, and Measles. The following are brief descriptions of the communicable disease hazards at Cal State LA.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It’s not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.  

**Measles**

Measles (also known as rubeola) is a highly contagious childhood infection caused by a virus. The measles virus replicates in the nose and throat of an infected child or adult. Then, when someone with measles coughs, sneezes or talks, infected droplets spray into the air, where other people can inhale them. The infected droplets may also land on a surface, where they remain active and contagious for several hours. The virus is contracted by putting touching one’s nose, mouth, or eyes after touching the infected surface.

Measles can be serious and even fatal for small children. The disease still kills more than 100,000 people a year worldwide, most under the age of 5. However, as a result of high vaccination rates in general, measles hasn't been widespread in the United States for more than a decade.  

**E. Coli**

Escherichia coli (E. coli) bacteria normally live in the intestines of healthy people and animals. Most types of E. coli are harmless or cause relatively brief diarrhea. But a few

---

strains, such as E. coli O157:H7, can cause severe stomach cramps, bloody diarrhea and vomiting. The E. coli O157:H7 strain belongs to a group of E. coli that produces a powerful toxin that damages the lining of the small intestine. Potential sources of exposure to E. coli O157:H7 include contaminated food or water – especially raw vegetables and undercooked ground beef – and person-to-person contact.

Signs and symptoms of E. coli O157:H7 include diarrhea (which may range from mild and watery to severe and bloody), stomach cramping, pain or tenderness, and nausea and vomiting. Infection can occur anytime from one day to one week after exposure to the bacteria, but usually begin three or four days after exposure.7

Location of the Hazard

Communicable diseases have the potential to affect the entire Cal State LA planning area equally. As a result, the communicable disease hazard can be found at the Cal State LA campus located in Los Angeles, CA (Los Angeles County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) at Cal State LA are at risk of exposure to the communicable disease hazard.8

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For CSU – Los Angeles, approximately 4% of its 26,361 enrolled students or 1,054 students reside in student housing.9,10 In the fall of 2021, a new student housing facility is opening adding 1,500 beds to the existing 1,054 beds for a total of 2,554 students (9.7%) residing in on-campus housing.

8 California State University. About CSU. Retrieved 4.29.2021 from: https://www2.calstate.edu/csu-system/about-the-csu
10 California State University. CSU Campus Match. Retrieved 04.30.2021 from: https://www2.calstate.edu/attend/campuses/campus-match/Pages/campus-match.aspx
Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 13-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall into these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

Figure 13-1: Biosafety Levels (BSLs)¹¹

---

The Extent of Cal State LA Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Measles and E. coli at Cal State LA. Measles would be classified at the BSL-2 containment level, and E. coli would be also classified at the BSL-2 containment level.  

The Extent of Cal State LA COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 198 cases of COVID-19 at Cal State LA. CSU-campus-specific COVID-19 case data for Cal State LA can be found in the “History of the Hazard” section below.

Most communicable disease data are maintained by the state and at the county levels, and are not generally available at the municipal or campus levels unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Following Tables show County-level COVID-19 Case data for Cal State LA. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Since March 2020, there have been 198 COVID-19 cases among students and employees reported to Cal State LA: 86 students, 74 employees and 38 contractors. These data reflect the number of individuals who have notified the university of their diagnosis.

Of the 86 students, 8 had the virus during a period of time when they were on campus or in instructional activity. Of the 74 employees with a diagnosis, 49 were on campus. The contractors were working at construction sites on campus when they were diagnosed.

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the CSU – Los Angeles campus. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contracts communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU – Los Angeles students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU – Los Angeles) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 13-6: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 13-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.
<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one’s hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

---

18 CDC/National Institutes of Health. *Biosafety in Microbiological and Biomedical Laboratories, 6th Ed.* Print. Retrieved 05.03.2021 from: [https://www.cdc.gov/labs/BMBL.html](https://www.cdc.gov/labs/BMBL.html)
These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

### Probability of Future Occurrence of the Hazard

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.

Table 13-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:
Table 13-8: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s system-wide probability ranking (below) reflects the ranking at the individual CSU campus level unless noted otherwise.

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at CSU campuses.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. As of Fall 2019, the CSU – Los Angeles had 26,361 students as well as additional faculty and staff. Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree in the current COVID-19 pandemic on the CSU-Los Angeles campus.19,20

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU-Los Angeles) are at risk of developing an extreme incidence of COVID-19 and may become “super-spreaders” for adjacent communities.21

19 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx
20 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. Several CSU campuses saw refund losses surpass $10 million. (See Figure13-2. below for the economic impact to the CSU – Channel Islands campus)

Figure 13-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs

**Mitigative Relief from Federal Assistance**

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 13-11) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 13-12 below for the “10% outbreak scenario” projections for the CSU-Los Angeles campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist...
is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Drought**

**Description of the Hazard**

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are
more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.

- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - Los Angeles) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified in Los Angeles where the campus is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic subset of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years. 28

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout the state (including Los Angeles) and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a risk to the geographic regions where CSU campuses are located, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies.

Although drought affects the entire CSU system wide planning area, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual

factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction.

Also, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels in California have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. These effects have not been reported on campus, but remain applicable concerns over the long term.

For CSU – Los Angeles, the extent of the hazard is Low (corresponding to D0-D1 on the extent scale below) and addressed through water conservation and conversion to drought resistant landscaping. However, the campus planning committee recognizes that the potential for more severe conditions exists and is tied to regional water resource vulnerabilities.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous. According to the US Drought Monitor, Time Series data, Los Angeles County has experienced five or more periods of drought covering 12 years over the past 20 years, and it includes the CSU - Los Angeles footprint.

Figure 13-3: Periods of Drought in Los Angeles County, California, 2000 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

---

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 31

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 13-4: Periods of Drought in State of California, 2001 – 2021 32

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the metropolitan area surrounding the CSU - Los Angeles campus:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2014–2017 period of the California drought cost the state's agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the

groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent. 33

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the CSU - Los Angeles campus planning area is a reduction in water availability for the municipal area tied to each campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). Though the campus does not have “Ag” programs or resources, the campus landscape (trees) is potentially impacted.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. 34 However, the wildfire hazard is analyzed separately in this plan. (See wildfire hazard).

In reviewing the occurrences of drought for CSU - Los Angeles, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2014-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - Los Angeles, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of campus level drought data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus=located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related

potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area. 35

At present, drought related damage to campus buildings and infrastructure at CSU - Los Angeles has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - Los Angeles is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Los Angeles. A reduction of electric power generation and water quality deterioration are also potential impact factors.

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that CSU - Los Angeles lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area. Although the probably of occurrence is highly likely, the impacts of drought to the campus are low.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Los Angeles campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows.
Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - Los Angeles planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

Vulnerability of Populations

Drought vulnerabilities on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerability measures apply to the students, faculty and staff of the CSU - Los Angeles campus.

Property Vulnerability

Drought vulnerabilities include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. Though property is not considered vulnerable currently, these same vulnerabilities may apply to the properties of the CSU - Los Angeles campus in the future.

---

**Natural Environment Vulnerability**

Natural environment vulnerabilities are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.39

**Critical Facilities Vulnerability**

Drought vulnerabilities for CSU - Los Angeles’ critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the city and county of Los Angeles, and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early

2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.

**Earthquake**

**Description of the Hazard**

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking — an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** — The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** — In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount
settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. Cal State LA is located in the eastern portion of the Los Angeles Basin. In general, fault systems surround and traverse through Los Angeles and Orange Counties including the area of Cal State LA. Throughout the basin the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 30-35 miles northeast of the Cal State LA campus. In addition to the San Andreas Fault, Los Angeles County is home to or near additional fault systems with the potential to generate strong ground shaking. The Elysian Park Fault extends across the southern boundary of the campus in an east to west direction. The Hollywood-Raymond Fault is another east to west fault 3 ½ miles north of the campus connecting Arcadia and Beverly Hills. The Puente Hills Fault extends from the southern base of the Puente Hills to downtown Los Angeles approximately 5 miles southwest of the campus. The Newport-Inglewood Fault traverses south to north paralleling the Orange County coastline extending 12 miles southwest of the Cal State LA campus. The Verdugo Fault extends from South Pasadena northwest to San Fernando 5 miles to the north of the campus. There are numerous additional faults in the area on all sides of the campus.
Figure 13-5: Faults located near Cal State LA

The Cal State LA campus reside outside of areas designated to be liquefaction zones. No campus facilities are located within the liquefaction zone. However, Substantial areas of the community surrounding the campus do reside within the liquefaction zone. This also includes major transportation corridors including Interstate 10, Interstate 710, Valley Blvd., and the Southern Pacific Railroad. The liquefaction zone generally follows the path of the Fullerton Creek.

Figure 13-6: Liquefaction Zones in Proximity to Cal State LA

---

Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground...
motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

Table 13-15: Modified Mercalli Intensity Scale

</tr>
</tbody>
</table>

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude
of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 13-7: Earthquake Magnitude and Equivalent Energy Release\(^{42}\)

![Diagram of Earthquake Magnitude and Equivalent Energy Release](https://www.usgs.gov/media/images/graph-showing-earthquake-magnitudes-and-equivalent-energy-release)

Extreme earthquake shaking potential exists in the Los Angeles County area, however, the Cal State LA campus resides outside of areas designated to be liquefaction zones. Also, no campus facilities are located within the liquefaction zone. That said, substantial areas of the community surrounding the campus do reside within the liquefaction zone. Based on the above factors, the campus planning committee ranks the extent of the earthquake risk to be Moderate.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Los Angeles County also has a long history of earthquake activity. The entire area of Los Angeles County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The January 9, 1994 Northridge Earthquake became the costliest seismic event in California history. The earthquake caused extensive damage to structures, the transportation infrastructure, utility systems, water storage, communications, and critical facilities. This level of damage due to the fault that ruptured was directly underneath a densely populated urban area. The Northridge Earthquake was found to raise the nearby mountains by as much as 70 centimeters. The earthquake was provided a federal disaster declaration (DR-1008).

The October 1, 1987 Whittier Narrows Earthquake shook a large part of southern California. The earthquake caused $358 million in damages, especially in the Alhambra, Pasadena, and Whittier areas. The earthquake resulted in extensive infrastructure damages, multiple injuries, and 8 fatalities. The earthquake was provided a federal disaster declaration (DR-799).

The February 9, 1971 Magnitude 6.5 San Fernando Earthquake struck the San Fernando Valley in Los Angeles just after 6am. The intense shaking caused the collapse of freeway overpasses, hospitals, and other infrastructure. It damaged thousands of homes and businesses, a reservoir, and critical infrastructure. 65 people were killed and 2,000 more were injured. The shaking was felt for 300 miles including in Las Vegas, Nevada. The earthquake was provided a federal disaster declaration (DR-299).

The March 10, 1933 Long Beach Earthquake registered at a Magnitude 6.4 occurred along the Newport-Inglewood Fault. The earthquake resulted in over $50 million in damages, 500 injuries, and 120 fatalities. Unreinforced masonry structures were the source of most of the casualties. 70 schools were destroyed and 120 were damaged. This earthquake

---

43 2019 County of Los Angeles All-Hazards Mitigation Plan, 2019
promoted statewide standards in building design and construction for schools and other structures to better withstand seismic events.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Los Angeles area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Hayward could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Los Angeles could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Los Angeles County region limiting immediate assistance that the campus may normally expect.

Local impacts to Cal State LA campus caused by an earthquake could include:

- Damage and secondary fires to industrial buildings to the west of campus
- Potential hazardous material releases on and off campus
- Potential liquefaction-based effects to areas of the surrounding neighborhoods to the west
- Infrastructure damage to freeway system
- Structural damage to bridges
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to flood control and drainage systems
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Los Angeles County fault systems surrounding Los Angeles is included in the following table.

Based on the earthquake shaking potential in the Los Angeles Basin, the history of occurrence, the proximity to the above listed fault systems, and the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of Cal State LA places the campus in an urban/suburban community near residential,

---

44 2019 County of Los Angeles All-Hazards Mitigation Plan, 2019
45 Southern California Earthquake Center, Earthquake Information,
commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to Los Angeles generally surround the city and some cross into the city including near the Cal State LA campus. The Elysian Park Fault traverses the southern edge of the campus. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected.

Elements of the vulnerability to a major earthquake on the Cal State LA campus will vary depending on when the earthquake were to strike. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. The Los Angeles area is densely populated and attracts numerous commuter employees to the urban core. The road and freeway network becomes easily congested in normal situations. As the Cal State LA campus is located at the intersection of Interstate-10 and Interstate-710, access in and out of the campus may be compromised with traffic congestion on these primary thoroughfares.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.
Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $257,007,988.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater Los Angeles Basin and the Cal State LA campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the Cal State LA campus and community.

In the event that a major earthquake were to strike along the many fault systems surrounding Los Angeles, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Los Angeles County region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

Vulnerabilities will be seen in the physical infrastructure on the campus and the human population of the campus community. Campus infrastructure is vulnerable to severe shaking particularly in areas where the ground is loose or susceptible to liquefaction. Specifically older buildings, masonry constructed buildings, and other structures susceptible to shaking related damage are the most vulnerable. Communication systems, computer networks, and other electronic systems may be vulnerable when overwhelmed by increased demand during emergencies or by shaking related damages. The people of the campus community are vulnerable to effects of intense shaking in the form of injuries from falling debris, exposure to secondary floods or fires, loss of employment, extreme disaster induced stress, and loss of access to critical services or social contacts.

The campus population is additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.
Erosion

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another”. Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While coastal erosion can happen in any storm, it is more likely during El Nino events, which occur every 5-7 years. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across those areas of the campus with erosion-prone characteristics. In the future, campus leadership may investigate to what extent specific erosion prone locations on the campus are exhibiting erosion in process.

Extent of the Hazard

Erosion is occurring on the Pacific coastline west of Cal State LA. While there is no published scale of severity or extent for this geologic hazard on the Cal State LA campus, erosion is likely to occur if conditions are favorable. Given no historical occurrence of erosion on campus, the planning committee ranks the extent of this hazard as Low.

History of the Hazard

El Nino storms from 2015-16 caused significant coastal erosion in Los Angeles County and mitigation projects are ongoing. However, no incidents of erosion have been recorded on the Cal State LA campus.

Potential Impacts of the Hazard

Coastal erosion can result in severe impacts to local infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

**Probability of Future Occurrence of the Hazard**

Erosion is an on-going and dynamic process that occurs regularly. As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. That said, with regard to the campus, given the lack of historical events or any known locations with erosion in process, the probability of annual future occurrence on campus is **Low**, though it is likely that at least a limited degree of erosion will occur somewhere on the campus over the long term; conditions could emerge in the future which increase the probability, precipitated by climate change, changes in land-use or other factors.

**Vulnerability to the Hazard**

Topography, soil structure, land use, and precipitation are all factors of erosion. Cal State LA infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion.

In the wider Los Angeles community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality. CSU leadership may consider performing an analysis on the campus to assess whether any specific at-risk buildings, slopes and soil types in the future.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

**Vulnerability Assessment Conclusions**

While the ability to predict future erosion on the Cal State LA campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**
The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.

**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Heat**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.48

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.49 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feels” hotter. The combination of temperature and humidity is known as the heat index.50

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.51 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.52

**Location of the Hazard**

Extreme heat events are a non-spatial hazard, and may occur throughout the Cal State LA campus.

**Extent of the Hazard**

50 Ibid.
Extreme heat has a wide range of extent and severity markers and characteristics. In the City of Los Angeles, monthly average maximum temperatures in June through October range approximately from the high 70s to the mid-80s. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at in the City of Los Angeles is 113° F on September 27, 2010. The day this record was reached, the National Weather Service’s high-tech thermometer in downtown Los Angeles stopped working.\textsuperscript{53}

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria.\textsuperscript{54} In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 13-8 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

Figure 13-8: Methodology for Determining Heat Index.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{Figure13-8.png}
\caption{Methodology for Determining Heat Index.}
\end{figure}

As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.

</tr>
</tbody>
</table>

Based on only five extreme heat events recorded in Los Angeles County since 1950, along with LA County’s established protocols of providing the public with advanced notice of heat events with directives for mitigating impacts, the planning committee ranks the extent of this hazard on campus as **Low**.

### History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been five excessive heat events in Los Angeles County since 1950. These events were consolidated within two periods in 2007 and 2008.

**August 30, 2007; September 1, 2007; September 3, 2007:** A combination of high temperatures and high humidity produced an extreme heat event across Los Angeles County and much of Southern California. Heat index values ranged from 105° to 112° F. There were eight deaths attributable to this excessive heat event.

**June 20, 2008; June 21, 2008:** Afternoon high temperatures during this extreme heat event climbed as high as 114° F. The heat resulted in several power outages due to excessive electrical use.

In addition to these excessive heat events, there have been 100 incidents since 1980 when the temperature in the City of Los Angeles has hit 100° F or greater (as reported by NCDC).

### Potential Impacts of the Hazard

Cal State LA may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

---

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

**Probability of Future Occurrence of the Hazard**

There have been no extreme heat events in Los Angeles County in over a decade, and only five events since 1950 according to NCDC data. Therefore, it is only possible that the hazard will occur annually. It is also important to note that the City of Los Angeles, where the Cal State LA campus is located, does not consider extreme heat to be a primary hazard, and has not included it in its most recent hazard mitigation plan. The rationale for excluding this hazard is that the combination of high temperature and high humidity, which are the requirements for the National Weather Service to declare a heat emergency, are relatively rare in Los Angeles. Los Angeles County, in its hazard mitigation plan, examines extreme heat as a hazard, but only as one small part of a larger discussion regarding the effects of climate change.

**Vulnerability to the Hazard**

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result. This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

---

57 2019 County of Los Angeles All-Hazards Mitigation Plan. 4.1 Climate Change. Print. Retrieved 01.27.21 from: https://lacounty.gov/emergency/county-of-los-angeles-all-hazards-mitigation-plan/
Cal State LA is aware of the potential for heat events and takes precautions to protect staff from the effects of the heat. When it comes to staff safety, supervisors are reminded of Occupational Safety and Health Administration (OSHA) regulations that protect workers from extreme heat.

Therefore, while this is a hazard that the campus may experience with regularity, the campus has ample familiarity with managing the risks and vulnerabilities.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the Cal State LA campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three degrees on average over the last century, with less rainfall. This may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.\(^59\) As such, it may lead to increased levels of those vulnerabilities discussed above.

Identified Data Limitations

Quantitative data on extreme heat impacts, such as public health impacts or impacts to campus power sources or air conditioning equipment is not available at this time.

Description of the Hazard (Extreme Cold)

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.\(^60\)

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until

someone else notices. This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underly tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes. It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases. The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6°F. Hypothermia occurs when your body temperature falls below 95°F. As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

Location of the Hazard

Extreme cold events are a non-spatial hazard, and may occur throughout the Cal State LA campus.

Extent of the Hazard

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in the City of Los Angeles are typically in the high 40s to low 50s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in Los Angeles was 33°F on January 17, 1987. Based on just 2 frost/freeze events in Los Angeles County since 1997, and no extreme cold events, the planning committee ranks the extent of this hazard as Low.

63 Ibid.
The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30°F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.\textsuperscript{65}

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure 13-9 (following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow).

Figure 13-9: Methodology for Determining Wind Chill

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{wind_chill_chart.png}
\caption{Methodology for Determining Wind Chill}
\end{figure}

In 2011, the National Weather Service introduced an experimental program that issued warnings for extreme cold events, independent of other severe weather warnings. The test areas included North and South Dakota and Minnesota. However, in 2012, after a

single season of use, the program was abandoned, based on reports of confusion among test audiences.66

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, Los Angeles County has had two frost/freeze events occurring December 21, 1998 and January 13, 2007, but no extreme cold hazards. [Records for this hazard were first recorded in 1996].

Potential Impacts of the Hazard

Should an extreme cold event occur, Cal State LA might experience impacts due to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

Probability of Future Occurrence of the Hazard

The City of Los Angeles has only experienced two frost/freeze events within the past two decades, but has never experienced an extreme cold event. Due to the campus’s location in a temperate climate, it is unlikely that this hazard will occur annually. As such, the planning committee ranks the probability of occurrence as Low.

Vulnerability to the Hazard

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more

likely to suffer illness or death as a result.\(^\text{67}\) This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Cal State LA is not one of the CSU campuses that is at high risk of an extreme cold event.

**Estimate of Potential Losses**

Based on the infrequent historical occurrences of cold/frost events, and no occurrence of extreme cold, annualized losses are considered to be negligible.

**Vulnerability Assessment Conclusions**

While the ability to predict future extreme cold events at the Cal State LA campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), areas in southern California have warmed approximately three degrees on average over the last century, with less rainfall. This may lead to fewer frost/freeze events in the future.\(^\text{68}\) As such, any existing vulnerabilities to cold will likely be reduced over the long term in Los Angeles.

**Identified Data Limitations**

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

**Flood**

**Description of the Hazard**

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry

floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplane
may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric River**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
The science behind atmospheric rivers

An atmospheric river (AR) is a flowing column of condensed water vapor in the atmosphere responsible for producing significant levels of rain and snow, especially in the Western United States. When ARs move inland and sweep over the mountains, the water vapor rises and cools to create heavy precipitation. Though many ARs are weak systems that simply provide beneficial rain or snow, some of the larger, more powerful ARs can create extreme rainfall and floods capable of disrupting travel, inducing mudslides and causing catastrophic damage to life and property. Visit www.research.noaa.gov to learn more.

Location of the Hazard

Cal State LA lies just under 5 miles from downtown Los Angeles. Along the eastern edges of Los Angeles are low rising hills that separate the Los Angeles Basin and the San Gabriel Valley. These include the Ascot Hills which provide a potential for developing water run-off during heavy localized precipitation events. The area surrounding the campus is a developed suburban environment predominately consisting of residential and commercial land uses. The campus is located at the junction of Interstate 10 and Interstate 710 on the northwest corner. A small flood retention basin is found on the opposite side of Interstate 710 from the campus.
The Cal State LA campus is not located in proximity to any significant waterways or flood control systems. The entire Cal State LA campus sits within a Special Flood Hazard Area (SFHA) Zone X: Area of Minimal Flood Risk designation on the Flood Insurance Rate Map. This minimal flood risk rating extends at least 4 miles away from the campus to nearest enhanced area of flood risk. Therefore, transportation routes and critical services in proximity to the campus are found outside of designated flood risks.

**Extent of the Hazard**

The Cal State LA campus is entirely located in a designated Zone X: Area of Minimal Flood Hazard. The access routes into and out of the campus servicing locations in all directions are also found in areas primarily designated as Zone X: Area of Minimal Flood Hazard. In addition, the Cal State LA campus lies outside of a levee flood protected area. Levees protect areas at the base of the foothills and lining flood control channels. This specific hazard does not substantially alter the ability of the campus to maintain operations as the distance to levee protected channels exceeds the protection zones. As such, the planning committee ranks the extent of the hazard on campus as **Low**.
In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 13-20: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised map in place of Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, BFEs derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
<tr>
<td>Zone AH</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.</td>
</tr>
<tr>
<td>Zone AO</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.</td>
</tr>
</tbody>
</table>
Zone X (shaded) | 0.2% | Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.

Zone X (unshaded) | Undetermined | Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.

History of the Hazard

No record of floods is recorded on campus, however, flooding in Los Angeles and the broader Los Angeles County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the Cal State LA campus.

**Potential Impacts of the Hazard**

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community
Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

**Probability of Future Occurrence of the Hazard**

Los Angeles County is determined have considerable portions of the county to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to flooding in any given year. Floods can occur at any time but are most common in the Los Angeles area with winter storms saturated with subtropical moisture. The topography of the area in and around Cal State LA does not generally promote conditions for flood waters to accumulate, although it is thought that specific parts of buildings and areas of the campus have a greater risk for isolated flooding (due to ponding from heavy rainfall). The Cal State LA campus is located within a Zone X Special Flood Hazard Area (Minimal Flood Hazard) and not in close proximity to areas with greater flood risk. However, there is a historic record of isolated urban or street flood events provides a demonstration of potential flood activity.

The probability of future occurrence for flooding is **Unlikely**.

**Vulnerability to the Hazard**

The Cal State LA campus is subject to the effects of limited and isolated flooding and small-scale ponding resulting primarily from excessive precipitation and isolated strong storms. There is a far more remote potential for flooding and damage on campus and surrounding residential and commercial areas of East Los Angeles due to overflow or damage to flood control systems. The flood control channels and drainage systems that surround the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems.

Vulnerability to flooding on the Cal State LA campus will vary depending on when the flood were to occur and on the location of people and assets located in low lying areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community may become trapped on campus depending on the level of flooding occurring on surface streets. However, in rare, region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

Cal State LA is in proximity to a commercial and industrial use facilities. In the unlikely event that these facilities are inundated with flood water, the potential for chemical release exists presenting possible exposures to individuals from the campus community.
These facilities additionally line many of the primary access routes in and out of the campus.

During very low probability, severe flood events, some campus buildings and infrastructure in low lying areas might be vulnerable to localized flooding affecting the university. Campus utilities and communication capabilities could be impacted by flood waters rendering them disabled. An extremely remote chance flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls, if located in low lying areas, may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. Flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Finally, certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $257,007,988. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods.

The potential for flooding on the campus and surrounding area, while unlikely, generates the added potential for cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Lack of comprehensive historic flooding occurrences, missing campus structural replacement costs, and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.
Hazardous Materials

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

Fixed Hazardous Materials Incident: A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

Transportation Hazardous Materials Incident: A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

Pipeline Incident: A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations

- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness

**Natural-Technological Incidents (Natechs)**: During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. Please refer to Annex ? for the map identifying the types and locations of hazardous materials and infrastructure on or near the CSU – Los Angeles campus. The planning committee indicates that chemicals are located in over 100 science labs across the campus. Also, the campus maintains a “90-day” facility for storing hazardous materials. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city and county of Los Angeles, and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

However, for the CSU – Los Angeles planning committee, several small-scale chemical spills have taken place on campus. In addition, an extensive and dense array of gas pipelines, rail lines, chemical and hazardous waste sites are located very close to the

---

campus. Based on these factors, it is prudent to rank the extent of the hazard for the CSU – Los Angeles campus as Moderate to High, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone. For more details on specific hazmat events, please refer to the local, county and/or multi-jurisdictional hazard mitigation plans where CSU campuses are located at: https://www.caloes.ca.gov/cal-oes-divisions/hazard-mitigation/hazard-mitigation-planning/local-hazard-mitigation-program

According to the campus planning committee, several small-scale chemical spills have taken place on the CSU – Los Angeles campus. Some events required building evacuation due to noxious odors which required fire department response and investigation. Also, one chemical event produced physical damage to the lab itself.

Potential Impact of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result

in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – Los Angeles campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak\(^78\), which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health.\(^79\) Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Los Angeles) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks,

manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the CSU – Los Angeles campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Moderate to High - the campus has experienced several chemical spill events and with 100 or more labs on campus, the risk of occurrence is multiplied. In addition, nearby hazardous materials and infrastructure further increase vulnerability and probability of a campus-related event. Moreover, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a large risk to the CSU – Los Angeles campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: chemicals are present in over 100 science and research labs, and the campus 90-day facility contains other hazmat material. In addition, gas pipelines and hazardous waste sites are extremely close to the campus footprint. Gases and chemicals or hazardous waste, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Los Angeles leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous
materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Los Angeles) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Los Angeles County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Los Angeles campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – Los Angeles planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
Landslide

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak

material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 13-13. Based on the Figure below, the campus is located directly adjacent to an area of moderate to high landslide susceptibility.

Figure 13-12: Deep-Seated Landslide Susceptibility Surrounding Cal State LA

Extent of the Hazard

In Los Angeles, landslides are more likely to occur in the steep slopes outside of the metropolitan area and along the coastline. The San Gabriel mountains, both steep and erosive, contain steeply walled canyons above areas with high population density. When heavy rain occurs, there is significant potential for floods and landslides throughout the

County, and the indirect impacts of landslides in the region may cover a larger geographical extent. The Cal State LA campus contains and is surrounded by areas of deep-seated landslide susceptibility. Based on the campus’ close proximity to the landslide hazard zone, and the history of significant impacts nearby in the city of Los Angeles, the planning committee ranks the extent of the landslide hazard for the campus as Moderate.

History of the Hazard

FEMA has declared thirteen major disasters involving landslides, mudslides, debris flows, or mud flows in Los Angeles County since 1978. NOAA has recorded five debris flow events in the County since 2004, most of which occurred in the areas directly surrounding metropolitan Los Angeles. The 2018 Southern California Mudflows damaged 40 to 45 homes in Sun Valley and caused a vehicle to strike a natural gas pipeline, which began to leak. Significant landslides have occurred in areas near the campus, though not in locations that would affect the campus directly; there is also no reported history of landslides on campus.

Potential Impacts of the Hazard

Cal State LA may be impacted by the disruption of services as a result of landslides in the region. Students, faculty, and staff who live in nearby communities may also be impacted. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are also often triggered by other natural hazards, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. According to the NCEI Storm Events Database, the City of Los Angeles has been impacted by earthquakes, wildland fires, and severe storms at least every other year since 1960. Given the historic frequency of these contributory sources to landslides and of recorded landslides themselves, the probability of future occurrence in the City of Los Angeles is high. However, while the location of the Cal State LA campus is in proximity to areas of high landslide susceptibility, there is no
reported history of landslides on campus. As such, the planning committee ranks the probability of the landslide hazard on the campus as **Unlikely**.

**Vulnerability to the Hazard**

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. The Cal State LA campus exhibits building and infrastructure and transportation route vulnerabilities to some degree.

Any population proximal to a landslide when it occurs is vulnerable to its impacts.

**Estimate of Potential Losses**

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to Cal State LA.

**Vulnerability Assessment Conclusions**

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**

The ability to predict future landslides at the Cal State LA campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.13

**Power Outage**

**Description of the Hazard**

Los Angeles, California is Los Angeles County’s largest city, and the country’s second largest and most populous city. Los Angeles is in a basin in Southern California and is home to the shores of the Pacific Ocean, large mountain ranges reaching up to 10,000 feet and valleys that experience extreme weather conditions throughout the seasons. Los
Angeles is rich in native plant species partly because of its diversity of habitats, including beaches, wetlands, and mountains. Due to its lush landscapes, hot summers and dry winters can create a significant amount of brush increasing fuel for brushfires within the city limits and within its large suburbs, like the San Fernando Valley, where other Cal State campuses reside, as well.

Most aspects of modern life rely on the near continuous availability of utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of power can affect the campus in various ways like forcing campus closures to limiting campus operations. These interruptions can produce cascading effects from other hazards, such as major windstorms, winter storms and wildfire, which can prompt an intentional disruption or Public Safety Power Shut Off (PSPS).

A power outage event can interrupt day-to-day operations of the campus, like in-person classes, impede, or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center and close restaurants around campus and outside the campus. Additionally, thousands of Cal State LA student residents in on-campus housing would also be affected by a power outage on campus.

Additionally, a severe outage to Los Angeles County or neighboring communities and cities would also directly affect the campus and the community.

An electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of **intentional** disruptions:

- Planned: Some disruptions are intentional and can be scheduled based maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities, and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. A power outage could affect the entire area of the campus, including the Cal State LA athletic fields, classrooms resident halls, administrative offices, virtual, telephonic and radio communications, leading to loss of lighting in campus parking structures, and creating a cascading hazard for commuters as they depart from or arrive to campus in the evening. Additionally, the university is located within proximity of highly utilized thoroughfares for the transportation of goods to throughout California, within one of the busiest areas of the Southern California.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. However, given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard
The City of Los Angeles has experienced power outages over time. Their electric utility provider, the Los Angeles Department of Water and Power (LADWP) has experienced outages, which have affected the residents of Los Angeles over the years. Major power outages impacting the City of Los Angeles in recent years have affected a large number of residents as seen below:

- **1994**: A 6.7-magnitude earthquake rumbled through Los Angeles at 4:30 a.m. causing a power outage citywide.
- **July 8, 2017**: an explosion at a Northridge power plant causes a widespread power outage in the San Fernando Valley, Los Angeles.

The Cal State LA campus has also experienced power outages:

- **March 16, 2005**: the campus experienced a power outage in the morning hours, but the university was able to continue operations despite the minor interruption of power.

Cal State LA did not report any power outages in the recent years, but did advise that the university is expanding their mitigation efforts by replacing sub-stations and upgrading outdated systems that may potentially exacerbate the probability of a power outage.

### Potential Impacts of the Hazard

Instructors, campus residents, staff, and administration rely on electricity for basic operations. During a widespread power failure, it may take anywhere from several hours to days to restore operations if a significant event occurs. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

### Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree
days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City of Los Angeles and Los Angeles County experience such outages. As such, the probability ranking for the Los Angeles area is **Likely**. Although the Cal State LA campus has recorded fewer events than the surrounding area, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

**Estimate of Potential Losses**

The data provided by Cal State LA does not report any value for potential losses due to power outage.

**Vulnerability Assessment Conclusions**

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Cal State LA. Vulnerable populations (especially students with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a
power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept to continue operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

Cal State Los Angeles did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.

Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of Cal State LA or Los Angeles County is within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While Cal State LA does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California.11 The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.12

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As Cal State LA is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at Cal State LA.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard
The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as **Unlikely**.

**Vulnerability to the Hazard**

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For Cal State LA, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

**Estimate of Potential Losses**

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

**Vulnerability Assessment Conclusions**

Cal State LA is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

**Identified Data Limitations**

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.
Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.
- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences

85 State of California Hazard Mitigation Plan, September 2018
conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. Cal State LA and the City of Los Angeles are located in the heart of the Los Angeles Basin. This area near the university is dominated by urban and suburban communities with limited direct exposures to wildland fire. Cal State LA has extensive residential neighborhoods to the north of campus and opposite from bordering freeways south and east of the campus. Industrial land uses are located to the west of the campus. The multi-lane Interstates 10 and 710 provide the eastern and southern borders of the campus.

The Cal State LA campus is located in the eastern side of Los Angeles bordering the City of Alhambra. The campus 1 mile southeast of the closest area designated as having a high fire hazard at Ascot Hills and Montecito Heights where there is a mix of residential neighborhoods and hillsides with moderate vegetative fuels. The campus is not located next to areas with a fire hazard potential making direct impacts by fire on the campus unlikely.

However, the Cal State LA campus is surrounded by mountains and extensive areas of fire hazards further away. Surrounding the Los Angeles Basin are large mountain ranges including the San Gabriel, San Bernardino, and Santa Ana Mountains. These mountain ranges host three national forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the basin in the right wind conditions. The geography of the Los Angeles Basin and San Gabriel, San Fernando, and San Bernardino valleys creates a topography that captures air pollutants including smoke within surrounding mountains and the development of inversion layers. The Cal State LA campus is located in a region in which wildfire smoke can saturate the air around the campus.
Extent of the Hazard

The area immediately surrounding the Cal State LA campus is near but not in immediate proximity to fire hazard zones designated as Very High Fire Hazard Severity Zones (VHFHSZ). The County is surrounded by areas that are considered to be of high fire threat and that would produce (and have produced) vast quantities of smoke and particulates into the air, affecting the air quality on the Cal State LA campus. As a result, the planning committee ranks the extent of the wildfire hazard for the Cal State LA campus as Moderate.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are

---

computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 13-23: National Fire Fire Danger Rating System87

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 4: Very High Danger (VH)</td>
<td>Fires start very easily and spread at a very fast rate</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is</td>
</tr>
<tr>
<td>COLOR CODE: Orange</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Los Angeles County also has a long history of wildfire activity primarily in the foothills and mountains of the San Gabriel and Santa Monica Mountains. Wildfires occurring in Los Angeles County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damages.

The area immediately surrounding the Cal State LA campus is near but not in immediate proximity to fire hazard zones designated as High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Los Angeles campus has experienced multiple days of poor air quality due to fires burning in Los Angeles, Orange, Riverside, and San Bernardino Counties. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Los Angeles County. Cal State LA personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

Potential Impacts of the Hazard

The location of the Cal State LA campus surrounded by areas of urban development removed from areas with a fire hazard places a minimal direct threat from wildfire to the campus. The potential impacts to wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts to the campus resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets

\textsuperscript{90} 2019 Los Angeles County All-Hazards Mitigation Plan, 2019
Air conditioning systems overwhelmed
Greater demands on air filtration systems
Greater demands on healthcare systems
Reduced outdoor work productivity
Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Los Angeles including the campus may be damaged resulting in power outages. Fire-related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the minimal wildfire threat potential in the area surrounding the Cal State LA campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered **Unlikely**.

Based on the wildfire threat potential in the area surrounding Southern California including the hills and mountains throughout the region, the volume of areas in elevated Fire Hazard Severity Zones throughout the southern portions of the state, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered **Possible**.

Vulnerability to the Hazard

The Cal State LA campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban/suburban area of East Los Angeles. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of the urban areas of Los Angeles. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved.
Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

Some areas of particular vulnerability on the campus includes:

- Students and staff engaging in outdoor activities when the air is determined to be unhealthy are vulnerable to adverse health effects.
- Buildings with ineffective HVAC or do not have HVAC will cause limitations in filtering of air during smoke filled days.
- Power outages or brownouts during days with high levels of smoke will limit shelter in place options during heat events in summer.
- Santa Ana wind events may push large volumes of smoke into Los Angeles.

The greater concerns regarding vulnerabilities to wildfire on Cal State LA are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Los Angeles Basin even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. Cal State LA students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the Cal State LA campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would
include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $257,007,988. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher. However, the location of the campus in an urban/suburban setting removed from hazard prone areas makes wildfire related damages unlikely.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Los Angeles County. However, wildfire incidents do not pose a direct risk to the Cal State LA campus. The location of the Cal State LA campus surrounded by densely developed residential, commercial, and industrial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The students, faculty, and staff of Cal State LA who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the campus. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.
Additionally, the topography of Southern California surrounded by mountains allows for smoke filled air to linger in the valleys of the Los Angeles Basin with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains generating tremendous quantities of smoke present tremendous health related vulnerabilities to members of the campus community. The campus community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, and Lightning)**

**Description of the Hazard**

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding. \(^91\) According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.” \(^92\)

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

---

Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including Cal State LA.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including

93 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat
95 Retrieved on 07.17.2021 from https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions
96 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
“atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.98

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including Cal State LA), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.99

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.100 The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.101 These storms affect (in varying degrees) all CSU campuses, including Cal State LA.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.102 Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.103 Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.104 Severe thunderstorms are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements:

---

98 Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\textsuperscript{105} \textsuperscript{106}

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.\textsuperscript{107}

- **Wind storm**: marked by high wind with little or no precipitation.\textsuperscript{108}

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\textsuperscript{109}

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.\textsuperscript{110}

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\textsuperscript{111}

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\textsuperscript{112}
Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

Wind Hazards

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure. Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including Cal State LA).

High Winds, Strong Winds, and Thunderstorm Winds

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\textsuperscript{117}

Please note: \textit{Straight-line wind} is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\textsuperscript{118} However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

Tornadoes

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\textsuperscript{119} This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\textsuperscript{120} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{121}

\textbf{Santa Ana Winds.} A type of wind hazard that is peculiar to Southern California is called a \textit{Santa Ana Wind}. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{122} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation.

\textsuperscript{118} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/
\textsuperscript{119} Retrieved on 07.15.2021 from https://www.earthnetworks.com/tornado/
\textsuperscript{120} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/
\textsuperscript{121} Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions
They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{123} (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

Figure 13-15: What Drives a Santa Ana Wind?\textsuperscript{124}

\textbf{Diablo Winds}. The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface...
pressure gradient that forms in response to an inverted pressure trough that develops over California.125

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.126 127 128

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.129 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.130

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\(^{131}\)

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\(^{132}\) Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the Cal State LA campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all Cal State LA campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to Cal State LA reflect those of the surrounding community and County. As a result, all assets and people at Cal State LA are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Los Angeles area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

---

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.\textsuperscript{133} First developed in 1805, it is still used today to estimate wind strengths.\textsuperscript{134}

Table 13-26: Beaufort Wind Force Scale\textsuperscript{135}

<table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{136}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the **date** that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

**Table 13-27: Fujita Tornado Scale (Pre-February 2007)\(^{137}\)**

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms.\textsuperscript{141, 142} That said, according to the \textit{Glossary of Meteorology} published by the American Meteorological Society (AMS), a thunderstorm is reported as \textit{light, medium, or heavy} according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\textsuperscript{143}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- \textbf{Airmass Thunderstorm}: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{144}
- \textbf{Frontal Thunderstorm}: An individual thunderstorm the initiation of which results from rising motion associated with a front, \textit{or} a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{145} or
- \textbf{Squall-line Thunderstorm}: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\textsuperscript{146, 147}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as \textbf{LOW}.

\textsuperscript{141} Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
\textsuperscript{142} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
History of the Hazard

Severe weather hazards have been an annual occurrence in Los Angeles County and on the Cal State LA campus. Historical data for these hazards are presented below.

Historical Storm Data Collection: NCEI Storm Events Database

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\(^{148}\) For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\(^{149}\) To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Los Angeles County since 1996.\(^{150}\) Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\(^{151}\)

- **High Wind**: at least 387 events, or approximately 15.28 events per year\(^ {152}\)
- **Strong Wind**: at least 3 events, or 0.12 events per year\(^ {153}\)

---

\(^{153}\) National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from [https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType%28Z%29=Strong+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&count](https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType%28Z%29=Strong+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&count)
Thunderstorm Wind: at least 43 events, or approximately 1.70 events per year.\textsuperscript{154}

All Wind Hazard events (excluding Tornadoes): at least 427 events, or approximately 16.86 events per year.\textsuperscript{155} (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Los Angeles County, there have been at least 427 wind hazard events since 1996, excluding tornadoes.\textsuperscript{156} That translates to an approximate average historical frequency of occurrence of 16.86 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 433 events) and simultaneous Database searches of all severe weather hazard events (i.e., 427 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Los Angeles County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{157} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 427 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical Wind Hazard Losses for Los Angeles County since 1996

According to the NCEI Storm Events Database, the wind hazard events that Los Angeles County has experienced since 1996 have been costly. There have been 2 deaths and 4

injuries reported from wind hazard events (excluding tornadoes) in Los Angeles County; no property or crop damage has been reported.158

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 12 reported events of tornadoes in Los Angeles County, which translates to approximately **0.47** tornado events per year.159

The vast majority of tornado reports in Los Angeles County since 1996 have been of tornadoes with a severity rating of F0/EF0. Only one (1) or 12 of the tornadoes reported in has been rated F1/EF1 or higher (it was an F1 tornado that occurred in 1998); that translates to approximately **0.04** events of F1/EF1 tornadoes have occurred per year in Los Angeles County.160

**Historical Tornado Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Los Angeles County has experienced since 1996 have been minimal. There have been no deaths, or property or crop damage reported; however, 1 injury has been reported.161 (Note: An F1/EF1 tornado that occurred in Los Angeles County in 1998 was responsible for the one (1) reported injury.)

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 18 reported events of hail in Los Angeles County, which translates to approximately **0.71** hail events per year.162 (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 19 reports of hail since 1996. However, one (1) entry

13-119
is for a hail event in San Diego County, over 100 miles away from Los Angeles County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Los Angeles County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damages reported, there have been property damage estimates that have totaled approximately $3,500,000; the property damage estimate reflects one (1) hail hazard event that occurred in 2003.\(^{163}\) (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Los Angeles County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 9 reported events of lightning in Los Angeles County, which translates to approximately 0.36 lightning events per year.\(^{164}\)

**Historical Lightning Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Los Angeles County has experienced since 1996 have been costly. While no property or crop damages have been reported, there have been 2 deaths and 13 injuries attributed to lightning hazard events.\(^{165}\)

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

---

Information obtained from the NCEI Storm Events Database indicates that there have been 466 occurrences of the severe weather hazard in Los Angeles County. This translates to **18.39 severe weather hazard occurrences per year**.\(^{166}\)

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 472 events) and simultaneous Database searches of all severe weather hazard events (i.e., 466 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado;” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Los Angeles County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{167}\)

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 466 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

### Historical, Aggregated Severe Hazard Losses for Los Angeles County since 1996

According to the NCEI Storm Events Database, the severe weather events that Los Angeles County has experienced since 1996 have been costly. There have been 4 deaths and 18 injuries, and property damage estimates have totaled approximately $3,500,000; no crop damage has been reported. *It is important to note that for all Los Angeles County severe weather hazard events recorded on the Storm Events Database, lightning has accounted for half of the deaths, and for 13 out of 14 (92.9%) injuries reported. However, hail has accounted for all estimated property damages.*

### Wind Hazards Not Included in the NCEI Storm Events Database

#### Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April.\(^{168}\)

From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of **32 occurrences per year**. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting

---

\(^{166}\) National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from [https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Hail&eventType=%28Z%29+HighWind&eventType=%28C%29+Lightning&eventType=%28Z%29+StrongWind&eventType=%28C%29+ThunderstormWind&eventType=%28C%29+Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=LOS%2BANGELES%3A37&hailfilter=0.0&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2,CCALIFORNIA

up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{169, 170}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Figure 13-16: Mean Annual Frequency of Santa Ana Wind events (1948-2012)\textsuperscript{171, 172}

**Diablo Winds**

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^\text{173}\)

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\(^\text{174}\)

Figure 13-17: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\(^\text{175}\)

---

**Sundowner Winds**

Strong sundowner wind events occur approximately **2-3 times per year**. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\(^\text{176}\)

* Note: The Diablo and Sundowner wind hazards are not present in Los Angeles County. They are included here for information purposes only.

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within Cal State LA campus areas are at risk from the effects of severe weather.

Wind Hazards (Including Tornadoes)

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the
campus. As with most university campuses, space is always at a premium at the Cal State LA campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

According to the City of Los Angeles 2018 Local Hazard Mitigation Plan, “Adverse Weather,” which includes hazards such as high winds and tornadoes, is considered to have high impact on people, and medium impact on property. As a result, wind hazards have a moderate to high potential impact on the city and (by extension) on the Cal State LA campus.177

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

The City of Los Angeles 2018 Local Hazard Mitigation Plan does not explicitly profile hail, as it is not considered to be a common adverse weather event in Los Angeles. As a result, hail hazards are considered to have a minimal potential impact on the city and (by extension) on the Cal State LA campus.178

**Lightning**

Lightning strikes the United States about 20-25 million times a year.179 Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.180 Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.181 (Commercial claim payouts for lightning losses for the U.S. were not available.)

The City of Los Angeles 2018 Local Hazard Mitigation Plan does not explicitly profile lightning, as it is not considered to be a common adverse weather event in Los Angeles. As a result, lightning hazards are considered to have a minimal potential impact on the city and (by extension) on the Cal State LA campus.\(^\text{182}\)

### Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The City of Los Angeles 2018 Local Hazard Mitigation Plan states that “adverse weather” hazards (i.e., wind and tornado) have a **high** probability of occurrence in Los Angeles.\(^\text{183}\) Also, according to the NCEI Storm Events Database, some of these same severe weather hazards (e.g., wind hazards) have occurred in surrounding County far more than once a year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the Cal State LA campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the Cal State LA campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both The City of Los Angeles 2018 Local Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the Cal State LA campus **at least once on an annual basis**. Therefore, the probability of future occurrence of the severe weather hazard for Cal State LA is **HIGHLY LIKELY**. See Table below for probabilities of future occurrence for component severe weather hazards for the county (including all city areas) and the campus.

Severe Weather Hazard Highly Likely

** Note: The Diablo and Sundowner wind hazards are not present in Los Angeles County, and therefore are not rated for probability of future occurrence. They are included here for information purposes only.

Vulnerability to the Hazard

People, structures, and assets on the Cal State LA campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The Cal State LA campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire Cal State LA campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.
All structures within the Cal State LA campus are at risk from severe weather. There are approximately 115 buildings on the main campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $257,007,988 for 87 of the buildings, and are unknown for the remaining 28 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at the Cal State LA campus varies throughout the day. As of Fall, 2019, Cal State LA had 26,361 students and 2,821 faculty and staff. All are at risk from severe weather events, with 29,182 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to the Cal State LA campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to Cal State LA.

It is evident that the Cal State LA campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection

services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
13.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the Cal State LA campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
Table 13-33: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>

</tbody>
</table>
Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.
Table 13-34: Campus-specific emergency management issues of concern and inclusion in emergency management plans and processes.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- In some important areas there were disagreement in answers. Table X answers are response averaged on these questions.
- Interviewee expressed robust interest in whether these issues need to be included in the emergency management planning processes and plans.
- DAFN is an issue of concern: Reflected in plans and they meet monthly on the press advisory committee, 14 on all different dept./ send out to all the building administrators so when emergency the floor monitors will look for the one person and the stairwell evac point
- The only issue for racial equity is campus protests and demonstrations of what is going one. It is an issue because of the large Latino population. Any inference of inequity and students engaged on social media will videotape and post. It is not reflected in plans but if needs to more robust they will incorporate it.
- Focused on corrective measures for Immigrants/immigration status issues (undocumented, DACA, etc.) Taking care of people when they don’t understand because of language barriers, it is an education piece, and recognized that students from other country sometimes “don’t react well.”
- Transportation dependency is an issue of concern because it is a heavily commuter campus with Metro Link adjacent to the campus. All rely on public transportation and are given incentives. It is a problem when public transport is down or when risk is involved, such as in COVID.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

</table>
**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods. Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states. Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely

---

challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.  

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and

---

inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.”

Flood

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such

as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. ¹⁹⁰

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural heath and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, sadness and grief. ¹⁹¹ Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms. These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

Hazardous Materials

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or

evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease. Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And,

---

192 [https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/](https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/)

in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning

---

processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

14.1 University Profile

University History

Cal Maritime was established as the California Nautical School in 1929 when the California State Assembly Bill no. 253 was signed into law by Governor C. C. Young. The bill authorized the creation of the school, appointment of a Board of Governors to manage the school and the acquisition of a training vessel. The school’s mission was "to give practical and theoretical instruction in navigation, seamanship, steam engines, gas engines, and electricity in order to prepare young men to serve as officers in the American Merchant Marine." By 1930, a training vessel and a school site in the San Francisco Bay Area city of California City (now Tiburon) had been acquired.

Due to the Great Depression, the early days of the Academy were full of financial uncertainty. As early as 1933, some state legislators were calling for the school's abolition. In order to save money, the cadets and instructors alike lived and held classes aboard the training vessel, the "T.S. California State". Only after the passage of the Merchant Marine Act of 1936 did the funding for the Academy become stabilized.

In 1939 the California Nautical School adopted its present name, the California Maritime Academy. By 1940 the Academy was granting Bachelor of Science degrees and Naval Reserve commissions to its graduates; this step marked the beginning of the transition from the status of trade school to college. During World War II, the Academy was evicted from its site in California City (Tiburon) and moved to its present location in Vallejo, California in 1943.

In the 1970s, after surviving another round of budget cuts and calls for the Academy's abolition, Cal Maritime became a four-year institution. The 1970s also marked the time when the first minority and female cadets graduated from Cal Maritime.

In 1996, Cal Maritime became the twenty-second campus of the California State University system. The new affiliation improved the academy's funding prospects considerably. As of Fall 2019, Cal Maritime was serving 911 students.

Today, Cal Maritime continues its mission of providing rigorous nautical training to cadets. The current training vessel for cadets is the "T.S. Golden Bear", and is the third training ship to carry that name.

Cal Maritime is the only degree-granting maritime academy on the West Coast of the U.S., and one of only seven in the nation. The school is designated as a Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide
office, reporting to the chancellor and participating in the system-wide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost is responsible for the academic integrity of the campus, the academic departments, faculty development, academic policy development and implementation, the assessment and accreditation of academic programs, the library, and student support programs, including admissions, continuing education, enrollment management, and financial aid. The Provost’s Council, with representation from these various areas, serves as the advisory body to the provost.

Additionally, all shipboard and waterfront training, and professional development of Academy cadets is managed by the Office of Marine Programs. This Office is headed by the Director of Marine Programs & Commanding Officer of Training Ship *Golden Bear*.

**University Mission**

The California State University Maritime Academy's mission is to:

 Provide each student with a college education combining intellectual learning, applied technology, leadership development, and global awareness.

 Provide the highest quality licensed officers and other personnel for the merchant marine and national maritime industries.

 Provide continuing education opportunities for those in the transportation and related industries.

 Be an information and technology resource center for the transportation and related industries.

 Cal Maritime’s uses the four (4) points of the compass to meet the university’s mission statement. The four elements are intellectual learning, applied technology, leadership development and global awareness; the latter requires all Cal Maritime students to spend time abroad as part of their education.

**University Location**

Cal Maritime is located in Vallejo, CA (population 121,722). The 92-acre waterfront campus is situated on the edge of San Francisco Bay, approximately 30 miles from San Francisco. Cal Maritime is one of only seven campuses granting maritime degrees in the U.S., and is the only maritime academy located on the West Coast.

**University Population**

In the Fall of 2019, Cal Maritime enrolled 911 students. Approximately 45.4% of the student population was White, followed by 22.4% Latinx students, 12.7% Asian American, Native American, and Pacific Islander students (combined), and 3.0% Black students. Additionally, 329 faculty and staff were employed by Cal Maritime.
14.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

14.3 Hazard Identification and Risk Assessment

Overview of Cal Maritime Academy History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA)
maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

**Hazard Identification**

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s *How-To Series*, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 14-1 (following).

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely**- 76%-100% that the hazard would occur annually.
- **Likely**- 50%-75% that the hazard would occur annually.
- **Possible**- 11%-49% that the hazard would occur each annually.
- **Unlikely**- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 14-2 below.)

**Descriptions of Identified Communicable Disease Hazards at Cal Maritime**

Cal Maritime has not provided information on communicable disease hazards that have had the greatest impact on its campus. However, it has provided COVID-19-oriented resources, guidance, and health and safety training to its cadets and employees, and has instituted protocols to protect those on campus from contracting COVID-19. Because of this robust response, it is assumed that Cal Maritime considers COVID-19 to be a communicable disease hazard.

The following is a brief description of the assumed communicable disease hazard (i.e., COVID-19) for Cal Maritime.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called
Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way.

The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.\(^5\)

Location of the Hazard

Communicable diseases have the potential to affect the entire Cal Maritime planning area equally. As a result, the communicable disease hazard can be found at the Cal Maritime Academy campus located in Vallejo, CA (Solano County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) the Cal Maritime land-based campus are at risk of exposure to the communicable disease hazard.\(^6\)

The communicable disease hazard can also be found on the T.S. Golden Bear, a training ship that serves as the primary training platform for Cal Maritime Cadets. Each summer, cadets in their first and third years depart with licensed faculty officers for the two-month Training Cruise.\(^7\) If there is any breach in communicable disease

---

\(^6\) California State University. *About CSU.* Retrieved 4.29.2021 from: https://www2.calstate.edu/csuintempl/about-the-csu

prevention protocols, the close quarters training ship environment could initiate, accelerate, and/or exacerbate any communicable disease hazard events.

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For Cal Maritime, approximately 85% of its 911 enrolled students (or 744 students) reside in student housing. 8,9

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 14-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

---

The Extent of Cal Maritime Communicable Disease Hazards Except COVID-19:

There was no information provided on communicable disease hazards on campus.

The Extent of Cal Maritime COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.  

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 10 cases of COVID-19 at Cal Maritime. Each CSU campus is an integral part of the surrounding community. Any event that occurs on a CSU campus has an effect on both the adjacent areas of campus and on the community-at-large – and vice-versa. Communicable disease hazard events are no exception. Most communicable disease data are maintained by at the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

---

Tables 14-5 and 14-6 show campus- and County-level COVID-19 Case data for Cal Maritime. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics have (and will continue to have) direct impact on life, health, and safety across the CSU system (including the Cal Maritime campus). The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of Cal Maritime students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic, and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including Cal Maritime) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk

Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.). ¹⁴

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 14-6: WHO Risk Group Categorization¹⁵

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 14-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall into these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 14-7: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG I</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
</tbody>
</table>
| RG 2  | Chicken Pox
Hepatitis A, B, C
Lyme disease
Salmonella
Mumps
Measles
Malaria
Scrapie
Dengue Fever
HIV | These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures. |
### RG 3

<table>
<thead>
<tr>
<th>Anthrax</th>
<th>West Nile Virus</th>
<th>SARS Virus (Including COVID-19)</th>
<th>Tuberculosis</th>
<th>Typhus</th>
<th>Yellow Fever</th>
<th>Hantaviruses</th>
<th>Avian Flu</th>
</tr>
</thead>
</table>

These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

### RG 4

<table>
<thead>
<tr>
<th>H5N1 (Bird Flu)</th>
<th>Dengue Hemorrhagic Fever</th>
<th>Marburg Virus</th>
<th>Ebola Virus</th>
<th>Smallpox</th>
<th>Lassa Fever</th>
<th>Crimean-Congo Hemorrhagic Fever</th>
<th>Other Hemorrhagic Diseases</th>
</tr>
</thead>
</table>

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are *not* available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

### Probability of Future Occurrence of the Hazard

There have been cases of a variety of communicable disease throughout the CSU system, including COVID-19 (SARS-CoV-2), Meningitis, Measles, Influenza (Including H1N1/Swine Flu), Tuberculosis, Norovirus, Mumps, E. Coli, and Sexually Transmitted Diseases (STDs). However, there are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.
Table 14-9: shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 14-8: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence. Note: Each communicable disease’s system-wide probability ranking reflects the ranking at the individual CSU campus level unless noted otherwise.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable disease hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at CSU campuses.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, the CSU System had 480,541 students and 53,763 faculty and staff.) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic at Cal Maritime. 17,18

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

---

17 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csusystem/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx  
18 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csusystem/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including Cal Maritime) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

Economic Impact of COVID-19 Pandemic on CSU Financial Health

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. Figure 14-2 below for the economic impact to the SJSU campus. Several CSU campuses saw refund losses surpass $10 million. (See 14-2.)

Figure 14-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs

---

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 14-11) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems. Table 14-12 shows the “10% outbreak scenario” projections both for each CSU campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.
Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

*Dam and Levee Failure*

**Description of the Hazard**

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures, as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtopping to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.
Location of the Hazard

The closest dam facility in proximity to Cal Maritime is the Swanzy Reservoir dam. This facility is an earthen dam that has a capacity of holding 107af of water. The dam sits in a valley ½ mile northeast of the campus. The height of the dam is higher in elevation than the campus but discharges its water to the northwest away from the campus. The access route into the campus (Maritime Academy Drive and Sonoma Blvd.) and the campus Aquatic Center are located within the dam inundation zone. There are no other dam facilities that are in proximity to the campus.

There are other Solano County dams that may have indirect effects to the Cal Maritime campus. The Lake Chabot Dam is 4 miles to the north of the campus affecting State Route 37 and north Vallejo neighborhoods. The Summit Dam and Reservoir is 5 miles north of the campus also affecting State Route 37 and north Vallejo neighborhoods. The Lake Herman Dam is 4 miles to the east of the campus and affects Interstate 680. A failure of these dams would likely cause significant disruptions across multiple transportation routes in Vallejo and Benicia.

There are no levees in the proximity of the Cal Maritime campus.
Figure 14-3: Dams and Levees Located Near CSU Maritime

Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

The Swanzy river dam discharges its water to the northwest away from the campus. It has the smallest capacity of all dams in the area. However, the access route into the campus (Maritime Academy Drive and Sonoma Blvd.) and the campus Aquatic Center are located within the dam inundation zone. Members of the campus community who reside or are employed in this area would be most impacted, while the campus would primarily experience interruptions to transportation routes. Based on these factors, and the fact that the dam undergoes regulated monitoring, maintenance and inspections, the planning committee ranks the extent of the hazard as Low to Moderate.

Extent – Levee Failure

There are no levees in proximity to the Cal Maritime campus. Therefore, the campus is outside of any levee protected zone. Based on these factors, the planning committee ranks the extent of the hazard as Low.

History of the Hazard

There are no records of dam or levee failures in areas that present a threat to the Cal Maritime campus. Solano County has no record of dam failures.

Potential Impacts of the Hazard

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning...
provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

**Levee Failure Impacts**

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

**Probability of Future Occurrence of the Hazard**

Solano County remains at risk from dam and levee failure. The facility most likely to impact Cal Maritime campus operations is the Swanzy Reservoir Dam. The facility is located ½ mile northeast of the campus. However, the location of the majority of the
Cal Maritime campus is located outside of identified dam inundation zone. There are no identified levees in proximity to the campus and thus the campus is outside of any levee protected zone. There are no official recurrence intervals that have been calculated for dam or levee failures. Based on no historical occurrences, and regulated dam maintenance and inspection protocols, the likelihood of this hazard is low, and the probability of future occurrence for both dam and levee failures is Unlikely.

**Vulnerability to the Hazard**

Given high priority monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. In addition, the campus does not lie within an inundation zone with the exception of the Aquatic Center and campus access routes. As such, the campus is not considered to be truly vulnerable on a daily basis. However, in the unlikely event of a catastrophic failure of the Suanzy dam, the effects of flooding on campus would most likely be limited to indirect or secondary effects in terms of disruption to regional transportation networks and services, and the amount of time to respond to the needs of the campus community prior to inundation will be limited.

Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations in the event of a low probability, catastrophic event.

Vulnerability to a dam or levee failure on the Cal Maritime campus will vary depending on the degree of breach or structural failure and when the failure were to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus
infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs are $83,596,545. This estimate is not inclusive of the entire campus as 31 campus facilities were included with cost estimates. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at Cal Maritime.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the Cal Maritime campus, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences could be catastrophic within inundation zones. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.
Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation.

Drought

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological
system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.

- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU – Maritime) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified throughout Solano County where CSU - Maritime is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to the campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years. 26

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk statewide, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies.

In addition, although drought affects the entire CSU system-wide planning area, the extent of the hazard may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities historically or potentially impacted by drought within each jurisdiction. More specifically, drought impacts have not been reported for CSU – Maritime.

---

In addition, land subsidence has occurred state-wide and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines, and the committee recognizes the possibility that CSU system-wide resources could be affected as long as drought conditions occur in the future.

For CSU – Maritime Academy, the extent of the hazard is Low (corresponding to D0-D1 on the extent scale below). However, the campus planning committee recognizes that the potential for more severe conditions exists and is tied to regional water resource vulnerabilities.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

| D3 | Water temperature increases; programs to divert water to protect fish begin |
|    | River flows decrease; reservoir levels are low and banks are exposed |
|    | Livestock need expensive supplemental feed, cattle and horses are sold; little pasture remains, producers find it difficult to maintain organic meat requirements |
|    | Fruit trees bud early; producers begin irrigating in the winter |
|    | Federal water is not adequate to meet irrigation contracts; extracting supplemental groundwater is expensive |
|    | Dairy operations close |
|    | Marijuana growers illegally tap water out of rivers |
|    | Fire season lasts year-round; fires occur in typically wet parts of state; burn bans are implemented |
|    | Ski and rafting business is low, mountain communities suffer |
|    | Orchard removal and well drilling company business increase; panning for gold increases |
|    | Low river levels impede fish migration and cause lower survival rates |
|    | Wildlife encroach on developed areas; little native food and water is available for bears, which hibernate less |
|    | Water sanitation is a concern, reservoir levels drop significantly, surface water is nearly dry, flows are very low; water theft occurs |
|    | Wells and aquifer levels decrease; homeowners drill new wells |
|    | Water conservation rebate programs increase; water use restrictions are implemented; water transfers increase |
|    | Water is inadequate for agriculture, wildlife, and urban needs; reservoirs are extremely low; hydropower is restricted |
|    | Fields are left fallow; orchards are removed; vegetable yields are low; honey harvest is small |
|    | Fire season is very costly; number of fires and area burned are extensive |
|    | Many recreational activities are affected |
|    | Fish rescue and relocation begins; pine beetle infestation occurs; forest mortality is high; wetlands dry up; survival of native plants and animals is low; fewer wildflowers bloom; wildlife death is widespread; algae blooms appear |
|    | Policy change; agriculture unemployment is high, food aid is needed |
|    | Poor air quality affects health; greenhouse gas emissions increase as hydropower production decreases; West Nile Virus outbreaks rise |

14-35
Water shortages are widespread; surface water is depleted; federal irrigation water deliveries are extremely low; junior water rights are curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor;

History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous. According to the US Drought Monitor, Solano County has experienced 8 periods of drought covering about 12 years between 2000-2021 and it includes the CSU - Maritime footprint, although drought impacts have not been identified for the campus.

Figure 14-4: Periods of Drought in Solano County, California, 2000 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply.

---

The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 30

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2- to 3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 14-5: Periods of Drought in State of California, 2001 – 2021 31

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state, (and according to the US Drought Monitor’s Time Series data) on Solano County and the city of Vallejo, which surrounds the CSU - Maritime campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a

remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.  

**Potential Impacts of the Hazard**

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the CSU - Maritime campus planning area is a reduction in water availability for the municipal area tied to the campus. Other potential impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - Maritime to some extent includes these vulnerable resources based on the campus landscape (trees).

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. However, the wildfire hazard is analyzed separately in this plan. (See wildfire hazard).

In reviewing the occurrences of drought for Solano County and the city of Vallejo, (where CSU - Maritime is located), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012 - 2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - Maritime, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campus. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No

---

data is currently available for tree mortality on campus; however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.  

At present, drought related damage to campus buildings and infrastructure at CSU - Maritime has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - Maritime is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Maritime. A reduction of electric power generation and water quality deterioration are also potential impact factors.

---

</tbody>
</table>

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that CSU - Maritime lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at

---

those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Maritime campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - Maritime planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2 million acre-feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

**Vulnerability of Populations**

The historical and potential impacts of drought on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of

---

37 National Oceanic and Atmospheric Administration National Centers for Environmental Information. *State Climate Summaries: California.* Retrieved 05.04.2021 from: [https://statesummaries.ncics.org/chapter/ca/](https://statesummaries.ncics.org/chapter/ca/)
drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the CSU - Maritime campus.

Property Vulnerability

Drought vulnerabilities include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the CSU - Maritime campus.

Natural Environment Vulnerability

The historical and potential impacts of drought on the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping. 38

Critical Facilities Vulnerabilities

Drought vulnerabilities at CSU - Maritime’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

Estimate of Potential Losses

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of Vallejo and the surrounding region such as crop loss and cost increases for water resources

have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

Vulnerability Conclusions

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

Identified Data Limitations

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.

**Earthquake**

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.
**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. Cal Maritime Academy is located in the northern area of the San Francisco Bay region. In general, fault systems surround and traverse throughout the Bay Area and Solano County including the area of Cal Maritime. Throughout the populated areas of Solano County and surrounding cities, the ground is saturated with sediment eroded from the hills by means of multiple stream channels. Liquefaction zones rated at moderate susceptibility exist on all sides of the campus.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 27 miles west of the Cal Maritime campus. In addition to the San Andreas Fault, Solano County is home to or near additional fault systems with the potential to
generate strong ground shaking. The campus is additionally in close proximity to more fault systems. The Franklin Fault traverses south to north along Mare Island less than ¾ mile west of the Cal Maritime campus. The Contra Costa Shear Zone extends south to north 20 miles in length from Walnut Creek through Vallejo 2 miles east of the Cal Maritime campus. The 80-mile-long Hayward Fault stretches from Milpitas to Sonoma County 9 miles west of the campus. The entire San Francisco Bay Area is saturated with numerous additional faults mostly paralleling the San Andreas Fault to the northwest. These fault systems are located on each side of the campus.

Figure 14-6: Fault Lines near CSU Maritime Academy

Extent of the Hazard
The extent or severity of earthquake damage is expressed in terms of magnitude, intensity, and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people,
structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

*IX* Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb. Damage great in substantial buildings, with partial collapse. Buildings shifted off foundations.

*X* Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations. Rails bent.

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 14-7: Earthquake Magnitude and Equivalent Energy Release

---

Numerous fault systems surround and traverse throughout the Bay Area and Solano County including the area of Cal Maritime, including the powerful San Andreas fault. Liquefaction zones rated at moderate susceptibility exist on all sides of the campus. Though only 1 extreme event (Loma Prieta, 1989) has struck the area, the planning committee ranks the extent of the hazard for the campus as Moderate.

History of the Hazard

One federally declared earthquake event has occurred in Solano County since 1950. The Loma Prieta earthquake struck the San Francisco Bay Area on October 17, 1989. The earthquake was caused by a slip along the San Andreas Fault. The duration of earthquake was 10 to 15 seconds and measured 6.9 on the Moment Magnitude (Mw) Scale. The earthquake caused the deaths of 63 people, injured 3,757 people, and left approximately 3,000-12,000 people homeless. Direct losses from this earthquake amounted to approximately $10 billion.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils on the campus and surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in Solano County area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Vallejo could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Solano County could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader northern San Francisco Bay region limiting immediate assistance that the campus may normally expect.

Local impacts to the Cal Maritime campus caused by an earthquake could include:

- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway and roadway system
- Compromised transportation routes for access, supplies, services, and evacuation
- Structural damage to bridges
- Damage to flood control and drainage system
- Environmental damage to waterways and streams
- Structural damage to waterfront facilities
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Damage to on-campus utility infrastructure
- Damage to campus reclaimed water system and capability to support fire suppression system
- Release of airborne asbestos from damaged older buildings
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby apartment complexes and residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

**Probability of Future Occurrence of the Hazard**

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Solano County fault systems surrounding the North Bay region is included in the following table.
The Solano County Hazard Mitigation Plan Update describes the probability of an earthquake Magnitude of 6.7 or greater in the San Francisco Bay Area over the next 30 years is 63%. The Plan further demonstrates that these estimations are being updated continuously to address updated analyses. There is a 31% probability of one or more magnitude 6.7 earthquakes striking the Hayward Fault within 30 years.51

Based on the earthquake shaking potential in the Solano County area, the proximity to the fault systems illustrated above, the probability of seismic ground shaking that would generate damage is considered Possible.

**Vulnerability to the Hazard**

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of Cal Maritime places the campus in a suburban community near residential, commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will potentially spill over onto the campus.

The known fault systems generating the threat to the San Francisco Bay region generally surround the area and some cross near the Cal Maritime campus. The campus resides in a region that is exposed to fault systems on all sides. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected.

</tbody>
</table>
Elements of the vulnerability to a major earthquake on the Cal Maritime campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the city. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. This may be heightened in the southwestern portions of the campus as this area has been identified as being within a liquefaction zone. As the Cal Maritime campus is downstream from dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

The San Francisco Bay Area and Vallejo in particular are moderately populated and attract commuter employees to the commercial cores. The road and freeway network becomes easily congested in normal situations. Solano County relies on Interstates 80 and 680 as the primary overland transportation routes combined with state highway alternatives. Bridges connect the North Bay to the East Bay communities. A major earthquake has the potential for rendering these critical lifelines and supply routes inoperable and forcing the campus community to be self-reliant for a period of time.
Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $83,596,545.

**Vulnerability Assessment Conclusions**

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater San Francisco Bay region, the North Bay, and the Cal Maritime campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the
potential for a major earthquake exists affecting the campus and causing extensive challenges to the Cal Maritime University campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding Vallejo, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader San Francisco Bay region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population is additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shocks continue. These effects are magnified for populations having specific vulnerabilities or access limitations. Populations having various limitations or specific needs may be vulnerable to reduced or eliminated access to essential services that have been rendered incapable to respond.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and lack of a complete inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

**Erosion**

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another”. Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as

---

storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the CSU Monterey Bay campus with erosion-prone characteristics.

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While coastal erosion can happen in any storm, it is more likely during El Nino events, which occur every 5-7 years.

Extent of the Hazard

Erosion is occurring on the Pacific coastline west of CSU Maritime. While there is no published scale of severity or extent for this geologic hazard on the CSU Maritime campus, erosion is likely to occur if conditions are favorable. Given the fact that there are no recorded incidents of erosion on campus, an no specific sites known to be imminently at threat of erosion impacts, the planning committee ranks the extent of this hazard as Low.

History of the Hazard

There are no recorded incidents of erosion on the CSU Maritime campus.

Potential Impacts of the Hazard

Coastal erosion can result in severe impacts to local infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.
Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion on campus, the probability of at least a limited degree of erosion taking place somewhere on the campus in the future is high over the long-term.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Maritime infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion.

In the wider Vallejo community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

Vulnerability Assessment Conclusions

While the ability to predict future erosion on the CSU Maritime campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
**Flood**

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding represents one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash
flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric Rivers**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.
These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.

Figure 14-8: The Science Behind Atmospheric Rivers

**The science behind atmospheric rivers**

An atmospheric river (AR) is a flowing column of condensed water vapor in the atmosphere responsible for producing significant levels of rain and snow, especially in the Western United States. When ARs move inland and sweep over the mountains, the water vapor rises and cools to create heavy precipitation. Although many ARs are weak systems that simply provide beneficial rain or snow, some of the larger, more powerful ARs can create extreme rainfall and floods capable of disrupting travel, inducing mudslides and causing catastrophic damage to life and property. Visit www.research.noaa.gov to learn more.

Location of the Hazard

Vallejo is located in Solano County on the north side of the San Francisco Bay. Solano County can experience flooding from overflowing streams and heavy precipitation events in low lying areas. These areas often experience shallow flooding impacting roadways and other areas where drainage is inadequate. The western side of Solano County is a coastal plain adjacent to the San Francisco Bay that gradually rises to the north and east at the Benicia Hills. The communities in western Solano County are densely populated with extensive residential neighborhoods. Within 2 miles of the campus are large industrial zones containing a variety of land uses including chemical facilities and distribution centers shipping different materials.

---

The Cal Maritime campus is located on the San Francisco Bay waterfront with hillside elevation limiting the flooding potential that exists in the low-lying areas. The campus is situated in a ravine rising into rolling hills 20-200 feet higher than the waterfront. Creek beds that have been carved into valleys among the hills surround the campus with Interstate 80 providing the northern and western borders. The entire Cal Maritime campus sits within a Special Flood Hazard Area (SFHA) Zone X: Area of Minimal Flood Risk designation on the Flood Insurance Rate Map.

Extent of the Hazard

The Cal Maritime campus is located entirely in a designated Zone X: Area of Minimal Flood Hazard. The access routes into and out of the campus servicing locations to the south and east are found in areas primarily designated as Zone X: Area of Minimal Flood Hazard, access routes to and from the north are primarily located in Zone X: Area with Reduced Flood Risk but portions of Interstate 80 cross into Zone AE: Areas with 1% Annual chance of Flooding. Based on these factors, and no history of flooding on campus, the planning committee ranks the extent of the hazard as Low.
In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 14-20: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>

<td>Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.</td>
</tr>
<tr>
<td>Zone X (unshaded)</td>
<td>Undetermined</td>
<td>Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.</td>
</tr>
</tbody>
</table>

**History of the Hazard**

A number of areas in unincorporated Solano County have a long history of seasonal flooding, often resulting in significant damage. Localized and regional flooding in the County has been a continuous occurrence dating back to 1862 when “The Great Flood” in Davis, Rio Vista, Elmira, and Dixon wiped out the entire area. Major Disaster Declarations at the Federal level have occurred 13 times as a result of major regional flooding caused by severe storms and heavy rains in California. State Emergency Disaster Proclamations for flood damage as result of severe storm and heavy rains have been declared 6 times from 1950 to present. In addition to the declared disasters within Solano County, the computer aided dispatch information was used to develop a list of flooding events by year.

Data from the Solano County Computer-Aided Dispatch System has recorded approximately 14 different flood incidents from 2001 to 2011. Table below provides a summarized list of the dispatch information by year, cause of hazard, date of event, number of calls regarding that event and the area affected. No history of flood events are reported for the campus.

**The Winter Storms of 2005 and 2006**

As one can see in the table, flooding from the winter storms of December, 2005 and January, 2006 generated large call volumes across the entire unincorporated county. These storms also caused flood damage to approximately 121 different properties in unincorporated Solano County. Total damage estimated by the county was in excess of $4 million dollars. Some residents had over 3 feet of flood water enter areas of their home. Septic tanks were flooded and some residents experienced contamination issues with their drinking wells. The 2005-2006 winter storms also affected the Solano County municipal complex. Due to the amount of precipitation and tidal action in a City of Fairfield drainage canal, floodwaters overtopped the nearby protecting
embankment and caused extensive flooding to the municipal complex. Flooding occurred in the Solano County Court House, Jail, Sheriff’s 911 Dispatch Center, Office of Emergency Services, Facilities Operations, Communications, and Grounds Building. Many County services were displaced temporary, including the 911 Dispatch Center and County court house services. The County was self-insured. Damages for the 2005-2006 flood incident totaled more than $286,000; the cost of displacement was not included.

Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Additionally, individuals who are unable to evacuate in time or refuse to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped
by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

Solano County has numerous areas that are determined to be at risk from flooding. The location of the Cal Maritime campus resides outside of any Special Flood Hazard Area and is along the waterfront and elevated in the hills south of Vallejo. Areas designated as a Special Flood Hazard Area remain at a distance from the campus. The potential exists for urban flooding due to heavy precipitation that overwheels drainage systems on campus.

Based on the (above) factors, the planning committee ranks the probability of future occurrence for flooding as Unlikely.

Vulnerability to the Hazard

The Cal Maritime campus is subject to the effects of limited and isolated flooding and small pockets of ponding primarily resulting from potential urban flooding due to heavy precipitation that overwheels drainage systems on campus, excessive precipitation during isolated heavy storms, river/levee overflow, or a combination of these. Creeks are located close to the campus and flow through the campus however present minimal potential for flooding and damage on campus and surrounding residential areas. The creek channels that surround the campus have limited storage or volume capacities and may present vulnerabilities to the transportation network servicing the campus.

Vulnerability to flooding on the Cal Maritime campus will vary depending on when the flood was to occur and the location of people and assets in any low lying areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community located in a low lying ponding area may become trapped on campus depending on the level of flooding occurring on surface streets. However, in rare, region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

The Cal Maritime campus is in proximity to a variety of industrial and commercial facilities in the surrounding communities. When these facilities are inundated with flood water, the potential for chemical or other hazardous materials release exists presenting possible exposures to individuals from the campus community. These facilities additionally line many of the primary access routes in and out of the campus.

During low probability, severe flood events, some campus buildings and infrastructure in low lying areas might be vulnerable to large-scale flooding if it
reaches the university. Campus utilities and communication capabilities would be impacted by flood waters rendering them disabled. A rare flood covering a large portion of the City of Vallejo might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls in low lying areas may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. In such areas, flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $83,596,545. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods.

The potential for flooding on campus, although limited, generates potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Data limitations include missing campus structural replacement costs, and an incomplete inventory of both building construction features and mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.
**Hazardous Materials**

**Description of the Hazard**

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”43 Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health.44 Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards:** fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)

---

- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. Please refer to the map (below) identifying the types and locations of hazardous materials and infrastructure on or near the CSU – Maritime campus. The planning committee has not identified specific locations of hazardous materials on campus, although identifying such locations (if present) is a campus priority. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the City of Vallejo and Solano County, and reflect different types, configurations and scales dispersed across these geographic areas.

---

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

However, for the CSU – Maritime planning committee, although spills have not been identified on campus, based on the types and levels of hazardous materials in the larger community, it is prudent to rank the extent of the hazard for the campus as Low to Moderate, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from
the Loma Prieta Earthquake alone.\footnote{US Geological Survey. \textit{The Loma Prieta, California, Earthquake of October 17, 1989 – Fire, Police, Transportation and hazardous Materials}. Retrieved 04.19.2021 from: \url{https://pubs.usgs.gov/pp/pp1553/pp1553c/}} That said, the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

**History of the Hazard**

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20\textsuperscript{th}, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.\footnote{Cal OES. \textit{Spill Report View}. Retrieved 04.21.2021 from: \url{https://w3.calema.ca.gov/operational/malhaz.nsf$defaultView?OpenView&Start=121&ExpandView}}

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

For more details on specific hazmat events, please refer to the local, county and/or multi-jurisdictional hazard mitigation plans where CSU campuses are located at: \url{https://www.caloes.ca.gov/cal-oes-divisions/hazard-mitigation/hazard-mitigation-planning/local-hazard-mitigation-program}

According to the campus planning committee, no chemical spills have taken place on the campus.

**Potential Impact of the Hazard**

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in

direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – Fresno campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak\(^50\), which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.\(^51\)

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses are at some degree of risk from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming

into contact with toxic substances due to the presence of synthetic and hazardous materials.

**Probability of Future Occurrence of the Hazard**

The probability of occurrence for a hazmat event on the CSU – Maritime campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low. That said, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

**Vulnerability to the Hazard**

Hazardous materials pose a risk to the campus. As identified on the hazmat map (see Location section), the following vulnerabilities are present on campus: a gas pipeline and a rail line are located close to the East and South borders of the campus footprint. Gases and chemicals being transported, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Maritime leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

**Estimate of Potential Losses**

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.
Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Maritime) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Solano County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Maritime campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – Maritime planning committee has not provided complete information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to hazardous materials control on campus over the long term.
**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in

---

areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 14-11. The Maritime campus is located adjacent to a small area of moderate landslide susceptibility, but due to its topography is not susceptible to direct impacts to campus assets.

Figure 14-11: Deep-Seated Landslide Susceptibility Surrounding Cal Maritime

---

**Extent of the Hazard**

The extent of landslide hazards in Solano County is limited to the steepest slopes found in the southeast and west. However, the indirect impacts of landslides in the region may cover a larger geographical extent. Based on these factors and the campus location, the planning committee ranks the extent of the hazard as **Low**.

---

History of the Hazard

FEMA has declared 7 major disasters that involved landslides, mudslides, or mud flows since 1982 in Solano County, all of which were a result of storms or flooding. The campus has no history of landslide occurrences.

Potential Impacts of the Hazard

Cal Maritime may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have not occurred frequently in Solano County and therefore are likely to occur only occasionally in the future. Based on the campus’ location, the planning committee ranks the probability of occurrence on campus as Unlikely.

Vulnerability to the Hazard

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress.

Any population proximal to a landslide when it occurs is vulnerable to its impacts. The campus’ vulnerability is limited to secondary impacts to access routes.

Estimate of Potential Losses

There are no current models for estimating potential losses from a landslide directly impacting the campus.
Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to Cal Maritime.

**Vulnerability Assessment Conclusions**

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**

The ability to predict future landslides at the Cal Maritime campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.

**Power Outage**

**Description of the Hazard**

California State University Maritime Academy (Cal Maritime) is located on the waterfront of Vallejo, California a city in Solano County. Vallejo is along the northeast shore of the San Pablo Bay, which is 30 miles north of San Francisco.

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly populated areas like Vallejo without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the Cal Maritime campus, like in-person classes, impede or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of Cal Maritime student residents in on-campus housing would also be affected by a power outage on campus and in the area.

Additionally, a severe outage to Solano County or the City of Vallejo would also directly affect the campus and the community creating social, economic, and potential health and safety impacts.
Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of **intentional** disruptions are:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- **Demand-Side Management:** Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- **Load Shedding:** When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- **Wildfire** that damages transmission lines.

**Location of the Hazard**

Although power outages can take place within a certain area, as a hazard, it has the potential to occur and affect the entire planning area equally.

**Extent of the Hazard**

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities and is thus the entity that coordinates statewide flow of
electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential Public Safety Power Shutoff (PSPS) event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as **Moderate**.

### History of the Hazard

Cal Maritime has not reported experiencing any power outages in recent years.

### Potential Impacts of the Hazard

Instructors, campus residents, staff, and administration rely on electricity for basic operations. During a widespread power failure, it may take anywhere from several hours to days to restore operations if a significant event occurs. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

### Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.
With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City of Vallejo and Solano County experience such outages. As such, the probability ranking for the Vallejo area is **Likely**. Although the Cal Maritime campus has not recorded power outage events, it is connected to the power grid of the surrounding area; as a result, it is prudent to assign this same ranking (i.e., “**Likely**”) for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the probability of future occurrences prompting intentional outages and creating unintentional power outages the hazard is high for the county in different areas but not specifically influencing Cal Maritime. Nonetheless, campus leadership would be well-advised to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

**Estimate of Potential Losses**

The data provided by Cal Maritime did not report any value for potential losses due to power outage.

**Vulnerability Assessment Conclusions**

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during
nighttime hours. The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Cal Maritime. Vulnerable populations (especially students, staff, and faculty with physical disabilities) may be the most heavily affected by loss of power, as they rely on elevators, entry ways with automatic doors, and locks and lights; a power outage would impede a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may have to be kept to continue operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

**Identified Data Limitations**

Maritime Academy did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.

**Tsunami**

**Description of the Hazard**

A tsunami is a wave triggered by any form of land displacement along the edge or bottom of an ocean or lake. Land displacement can be in the form of submarine landslides or submarine dip-slip faults. These types of faults cause ruptures that result in seafloor uplift or down-drop. This mass movement translates to a tsunami or gravity wave within the overlying water at the surface.

Tsunamis travel radially outward from the area of initiation. The size of a tsunami is proportional to the mass that moved to generate the tsunami. As a tsunami approaches the shore and the depth of the water column decreases, the energy in the wave pushes the wave crest above the water surface resulting in a larger wave height. Wave runup is the elevation above mean sea level on dry land that a tsunami reaches. Run-up is what causes inundation of coastal areas that are below the run-up height.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing severe damage to coastal development. At the shoreline, tsunamis may take
the form of a fast-rising tide, a cresting wave, or a bore (a large, turbulent wall-like wave). The bore phenomenon resembles a step-like change in the water level that advances rapidly (from 10 to 60 miles per hour). The first wave is usually followed by several larger and more destructive waves.

**Location of the Hazard:**

According to the 2018 CA State Hazard Mitigation Plan, tsunami locations span 94 incorporated communities and 83 unincorporated areas across 20 coastal counties.

As identified on the map (below), the CSU – Maritime campus is located approximately \( \frac{1}{2} \) mile from the tsunami inundation zone. The campus is located on a bluff above the coastal inundation area.

Figure 14-12: CSU Maritime Academy Tsunami Inundation Area
Extent of the Hazard

The factors shaping the extent or severity of the hazard are a combination of geophysical forces (the amount of vertical and horizontal motion of the sea floor, the area over which it occurs, and the efficiency with which energy is transferred from the earth’s crust to the ocean water) and the geographic range of coastal development to be impacted.

More specifically, as a tsunami approaches the shore, wave run-up is the elevation above mean sea level on dry land that a tsunami reaches. A tsunami’s potential severity can be forecasted as a function of the wave’s mass along with the difference between the wave’s run-up height and the ground elevation of the affected coastal location.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.55

Although no record of tsunami losses have taken place in Vallejo CA, the infamous 2011 tsunami that devastated parts of Japan also arrived in the East Bay 10 ten hours later at just over a foot in height. Although the campus lies outside the inundation zone, the planning committee ranks the extent of tsunami as Moderate given that the campus lies close to the inundation zone and may be secondarily impacted by displaced evacuees. Moreover, since 1854, more than 71 tsunamis have been recorded in San Francisco Bay, most often generated by earthquakes in subduction zones near Russia, Japan or Alaska.

History of the Hazard:

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. That said, no tsunamis have impacted CSU campus locations.

According to the National Centers for Environmental Information (NCEI), have been eight tsunamis have caused damage to ports and harbors or coastal inundation in California since 1946. The most significant events are as follows:

---

In 1964, a tsunami caused by a Magnitude 9.2 earthquake offshore from Alaska resulted in 13 deaths in California and destroyed portions of downtown Crescent City.

A 2006 tsunami (originating in the Kuril Islands region north of Japan) caused approximately $20 million in damage to Crescent City harbor.

A 2010 tsunami (originating offshore from Chile) caused millions of dollars in damage to ports and harbors in the state.

A tsunami in 2011 (caused by a Magnitude 9.0 earthquake offshore of Japan) killed one person at the mouth of the Klamath River and caused up to $100 million of damage to 27 ports, harbors, and marinas throughout the State. The most damage occurred in Crescent City, Santa Cruz and Moss Landing harbors and a federal disaster was declared in Del Norte, Santa Cruz, and Monterey Counties. Both Crescent City and Santa Cruz harbors sustained damage to all docks, and oil spills and water/sediment contamination that resulted from sunk or damaged boats. Because recovery efforts in these two harbors took several years to complete, both harbors incurred business/economic losses that have been difficult to recapture.

Tsunamis That Have Affected North Coast California

- 03/20/1855: M 6.0 Earthquake; Humboldt Bay; wave height/feet (0.0)
- 11/24/1885: Meteorological Event Eureka; wave height/feet (0.0)
- 04/01/1946: M 8.6 Earthquake, Unimak Island, AK Humboldt Bay; wave height/feet (0.0)
- 03/28/1964: M 9.2 Earthquake, Prince William Sound, AK
  - Trinidad; wave height/feet (8.9)
  - King Salmon Slough, Humboldt Bay; wave height/feet (4.5)
  - Humboldt Bay; wave height/feet (6.2)
  - North Spit, Humboldt Bay; wave height/feet (3.1)
  - Municipal Marina, Eureka; wave height/feet (5.1)
  - Pacific Gas & Elec., Humboldt Bay; wave height/feet (3.8)

- 4/25/1992: M 7.2 Earthquake, Cape Mendocino, N. CA
  - Trinidad; wave height/feet (3.0)
  - North Spit, Humboldt Bay; wave height/feet (0.7)
  - Clam Beach; wave height/feet (0.0)

---

56 Global Historical Tsunami Database, National Center for Environmental Information, 2019
- 11/17/2003: M 7.8 Earthquake, Rat Islands, AK North Spit, Humboldt Bay; wave height/feet (0.2)
- 06/15/2005: M 7.2 Earthquake, N. California North Spit, Humboldt Bay; wave height/feet (0.1)

Since 1854, more than 71 tsunamis have been recorded in San Francisco Bay, most often generated by earthquakes in subduction zones near Russia, Japan or Alaska.

Finally, in 2011, a tsunami that devastated parts of Japan also arrived in the East Bay 10 ten hours later at just over a foot in height.

Potential Impacts of the Hazard:

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing total devastation to coastal development.

The configuration of the coastline, the shape of the ocean floor, and the characteristics of advancing waves play important roles in the destructiveness of the waves. Bays, sounds, inlets, rivers, streams, offshore canyons, islands, and flood control channels may cause various effects that alter the level of damage. Offshore canyons can focus tsunami wave energy, and islands can filter the energy. It has been estimated that a tsunami wave entering a flood control channel could reach a mile or more inland, especially if it enters at high tide. The orientation of the coastline determines whether the waves strike head-on or are refracted from other parts of the coastline.

For Solano County, potential impacts include destruction of the natural environment, destruction of boats as well as other coastal development, and loss of life. Tsunamis that impact both harbors and communities also can produce free-floating debris hazards and environmental contamination from chemical spills. Finally, an exceedance of the local emergency management and response capacity (including evacuee management) define the secondary or indirect impacts to the campus.

Probability of Future Occurrence of the Hazard:

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. If we consider historical occurrence as one data set for estimating future events, the average rate of occurrence over the past 150 years is 1 tsunami every 1.9 years. And for overall San Francisco Bay Area, 71 tsunamis over the past 165 years (1854-2019) produces an annual recurrence interval of 1 event every 2.3 years. As such, the planning committee ranks the future occurrence of the hazard as Likely over the long term.
That said, the rate of future occurrence may change and may be able to make target estimates for specific locations in the future; the California State Tsunami Program is trying to refine the accuracy of the data. In doing so, the State Tsunami Program is completing a set of Probabilistic Tsunami Hazard Analysis (PTHA) maps representing risk levels from 100-year to 3000-year average return periods. Analysis using these probabilistically based products will allow for a more common platform for comparison to other seismic and flood probabilistic analyses. 57

Vulnerability to the Hazard

With regard to CSU campus locations, direct vulnerability of assets and people to tsunami only applies to the CSU Chancellor’s Office in Long Beach, CA, as it is the only campus located in a mapped tsunami zone.

With regard to CSU – Maritime’s vulnerabilities, while no campus assets have been identified, the campus planning committee indicates that the California Geologic Survey datasets associated with Tsunami inundation zones might be utilized in the future if it is determined that any critical assets on, or owned by the campus fall within zones of vulnerability or if the campus is determined to be vulnerable to secondary impacts.

Population Vulnerability

The populations most vulnerable to the tsunami hazard are the elderly, disabled and very young who reside near beaches, low-lying coastal areas, tidal flats and river deltas that empty into ocean going waters. In the event of a local tsunami generated near the coast, little warning time would exist, so more of the population would be vulnerable, and this vulnerability may pertain to the Humboldt State University planning area. According to the campus planning committee, a tsunami could create isolated islands of people due to the inundation, and no evacuation or access to hospital services.

Property Vulnerability

The impact of tsunami waves and the scouring associated with debris that may be carried in the water could be damaging to all structures along beaches, low-lying coastal areas, tidal flats and river deltas. The most vulnerable structures are those in the front line of tsunami impact and those that are structurally unsound. According to the campus planning committee, it is thought that some degree of research equipment and research vessels are occasionally docked or moved in and around mapped tsunami zone coastal areas.

Critical Facilities and Infrastructure Vulnerabilities

The following vulnerable infrastructure is located in coastal areas of Solano County, CA:

57 2018 State of California Hazard Mitigation Plan
• Water Proximate Infrastructure—Breakwaters and piers collapse, sometimes because of scouring actions that sweep away their foundation material and sometimes because of the sheer impact of the tsunami waves.

• Flood Control Systems—Floodwaters can back up drainage systems, causing localized flooding. Culverts can be blocked by debris from tsunami events, also causing localized urban flooding.

• Utility Systems—Floodwaters can get into drinking water supplies, causing contamination. Sewer systems can be backed up, causing waste to spill into homes, neighborhoods, rivers and streams. Tsunami waves can knock down power lines and radio/cellular communication towers. Power generation facilities can be severely impacted by wave action and by inundation from floodwater.

• Fuels— Destruction of fueling infrastructure and related environmental and potable water contamination can occur.

Estimate of Potential Losses

Estimates of potential tsunami losses specific to Solano County have not been conducted yet. However, for the East Bay region (including Solano County), the HAZUS analysis indicated that 57 port systems have a replacement value of over $206B dollars. Given the potentially catastrophic nature of tsunamis, this should be considered realistic.

Vulnerability Assessment Conclusions

According to the 2018 State of California Hazard Mitigation Plan, community exposure to tsunamis in California varies considerably—some communities may experience great losses that reflect only a small part of their community and others may experience relatively small losses that devastate them. Solano County is among the 94 incorporated communities and 83 unincorporated areas that are most vulnerable to injury and life safety from tsunamis.

To improve tsunami vulnerability assessments, FEMA has developed a new tsunami loss estimation module for HAZUS using existing numerical model results for tsunami inundation, flow depth, velocity, and force. This HAZUS module allows new capability for estimation of economic losses, and site-specific analysis of content losses, casualties, infrastructure damage, and evacuation time. The module calibrates losses based on safe zones and community preparedness levels. Such technological improvements in assessment capability can be utilized for tsunami hazard analysis and planning purposes for CSU - Maritime.

Along with new probability-based tsunami maps, the HAZUS module will improve the ability to compare tsunami impacts to those of other hazards. Moreover, the probability mapping will be used for numerous applications including identifying potential tsunami hazard “zones of required investigation” under the Seismic Hazards Mapping Act and will assist state and local agencies in making land use planning
decisions and will help regional and state planners understand the flood potential from tsunamis representing different risk levels. The improved analysis and data will be utilized by Humboldt State University through its partnerships with key stakeholder organizations.\(^{58}\)

**Note:** To download the Community Exposure to Tsunami Hazards in California report visit the USGS website: [http://pubs.usgs.gov/sir/2012/5222/](http://pubs.usgs.gov/sir/2012/5222/).

**Identified Data Limitations**

As identified in the Vulnerability Summary (above), with regard to the current planning effort, the primary data limitations for assessing the tsunami hazard are comprehensive asset valuations lying within the tsunami inundation zone, and the need to apply FEMA’s new probability mapping techniques and tsunami loss estimation module to the footprint of each campus. That said, CSU leadership and planning teams intends to pursue such data in the future.

---

**Volcano (Associated Air Quality)**

**Description of the Hazard**

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”\(^{59}\)

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.\(^{60}\)

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

**Location of the Hazard**

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are

---

\(^{58}\) 2018 State of California Hazard Mitigation Plan

considered active volcanoes. No portion of Cal Maritime or Solano County is within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While Cal Maritime does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California.11 The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.12

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As Cal Maritime is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at Cal Maritime.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Low.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For Cal Maritime, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

Cal Maritime is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.
**Wildfire**

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.
- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to...
contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. The Cal Maritime campus is located in a suburban setting along the San Francisco Bay waterfront. This plain is surrounded by hills largely covered in moderate to high fuel density areas. In general, areas considered to be within Local Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur east and west of the campus. These hills surrounding Solano County communities can be topographically diverse, contain heavier vegetative fuels, and often have residential development interspersed.

The Cal Maritime campus is located in the southern portion of the City of Vallejo. The area immediately surrounding the campus is predominately waterfront and developed with residential land uses. Residential neighborhoods exist to the north and west of the campus. The campus has open fields to the east of the campus and opposite of Interstate 80. The area to the east of campus has a history of wildfire events but is not designated as a Local High Fire Hazard Severity Zone. To the north of the campus, are residential neighborhoods and valleys containing creek beds and containing heavy fuels.
Extent of the Hazard

The area immediately surrounding the Cal Maritime campus is not designated as High Fire Hazard Severity Zones. However, the campus is bordered on two sides by such zones made up of hillsides and open lands containing combustible vegetation combined with residential development and a history of wildfire activity. Cal Maritime also has a history of wildfire activity occurring both within proximity to and directly on its campus. As a result, the planning committee ranks the extent of the wildfire hazard for the Cal Maritime campus as High.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can

---

quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

**Table 14-22: National Fire Danger Rating System**

<tr>
<td>CLASS 1: Low</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
