Section 01
Introduction

1.1 Overview

On October 30, 2000, the President signed into law the Disaster Mitigation Act of 2000, also known as DMA 2000. Among its other features, DMA 2000 established a requirement that in order to remain eligible for federal disaster assistance and grant funds, local and state governments must develop and adopt hazard mitigation plans. On February 26, 2002, the Federal Emergency Management Agency (FEMA) published an Interim Final Rule (IFR) that set forth the guidance and regulations under which such plans are supposed to be developed. The IFR provides detailed descriptions of both the planning process that states and localities are required to observe and the contents of the plan that emerges.

This California State University (CSU) Hazard Vulnerability and Risk Assessment (HVRA) serves as a component of the hazard mitigation plan process, that will support the larger California State Hazard Mitigation Plan.

Hazard mitigation is often defined as actions taken to reduce the effects of natural hazards on a place and its population. California State University developed this HVRA because of increasing awareness that hazards have for the potential to affect people, physical assets, and operations throughout the university system.

Each campus, as well as the Chancellor’s Office, within the CSU system has chosen separate hazards that are applicable to their individual areas. The HVRA includes detailed descriptions of the process that was used to assess and prioritize the planning area’s risks from and vulnerability to hazards, and quantitative and qualitative risk assessments for each campus. The Planning Team considered such factors as the history of occurrence, the probability of a future occurrence, the potential vulnerabilities in their communities, and the availability of data regarding the hazard. After discussion and consideration, the Planning Team for each campus determined the hazards that had the potential to impact the entire planning area.

2.1 Description of the Planning Process

The California State University Hazard Vulnerability and Risk Assessment (CSU HVRA) project evaluated natural hazard risk for all 23 Campuses and the Chancellor’s Office and focused on both individual and campus-wide hazard vulnerability.

Two planning teams were established: a Core Planning Team and Campus Planning Teams. The Core Planning Team was smaller and made overall decisions on the direction of the HVRA. The Campus Planning Team consisted of at least one member from each campus that provided representation and assisted with coordination at the campus level.

Both Planning Teams participated in a project kickoff call in September 2020 to discuss the scope, schedule, and expectations of the HVRA project. Also in September 2020, the Core Planning Team met to select the overall hazards that would be included as part of the planning process.

Individual campus meetings were conducted with each campus to select the applicable hazards for the HVRA and to discuss campus hazard history details, capabilities, and social resilience.

There were other Planning Team Meetings to discuss project outcomes and draft review processes as well as to address any follow-up items from the campuses.

2.2 Review and Incorporation of Other Plans, Studies, Reports, and Other Information

Throughout the HVRA, other plans, studies, reports, and information were collected, reviewed, and incorporated into this HVRA. A file structure with those documents is included as part of the final HVRA deliverable.

3.1 University Profile

Individual California State Colleges were brought together as a system by the Donahoe Higher Education Act of 1960. In 1972, the system became The California State University and Colleges, and then in 1982, the system became The California State University.
The CSU System is currently made of 23 campuses across California and nearly 500K students are enrolled annually. CSU has one of the most diverse student bodies in the United States.

3.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate.

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.
3.3 Hazard Identification and Risk Assessment

Overview of California State University’s History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Core Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered by the Core Assessment Team, including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Core Assessment Team members.

In the initial phase of the planning process, the Core Assessment Team considered 14 hazards and the risks they create for the University system-wide footprint and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 3-1 (following).
<table>

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- Highly Likely- 76%-100% that the hazard would occur annually.
- Likely- 50%-75% that the hazard would occur annually.
- Possible- 11%-49% that the hazard would occur annually.
- Unlikely- 0%-10% that the hazard would occur annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent.¹ They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions.² The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.³

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)⁴

Descriptions of Communicable Disease Hazards by CSU System Campuses

The following are brief descriptions of each of the nine (9) communicable disease hazards that have been identified across the CSU system. The descriptions are presented in decreasing order of frequency.

COVID-19 (SARS-CoV-2)

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome

---

(MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death. ⁵

**Meningitis**

Meningitis is an inflammation of the fluid and membranes (meninges) surrounding the brain and spinal cord. The swelling from meningitis typically triggers signs and symptoms such as headache, fever and a stiff neck. Early meningitis symptoms may mimic the flu (influenza). Symptoms may develop over several hours or over a few days.

Most cases of meningitis in the United States are caused by a viral infection, but bacterial, parasitic and fungal infections are other causes. Some cases of meningitis improve without treatment in a few weeks. Others can be life-threatening and require emergency antibiotic treatment. Bacterial meningitis is particularly serious and can be fatal within

---

days without prompt antibiotic treatment. Delayed treatment also increases the risk of permanent brain damage or death.\(^6\)

**Measles**

Measles (also known as rubeola) is a highly contagious childhood infection caused by a virus. The measles virus replicates in the nose and throat of an infected child or adult. Then, when someone with measles coughs, sneezes or talks, infected droplets spray into the air, where other people can inhale them. The infected droplets may also land on a surface, where they remain active and contagious for several hours. The virus is contracted by putting touching one’s nose, mouth, or eyes after touching the infected surface.

Measles can be serious and even fatal for small children. The disease still kills more than 100,000 people a year worldwide, most under the age of 5. However, as a result of high vaccination rates in general, measles hasn't been widespread in the United States for more than a decade.\(^7\)

**Influenza (Including sub-type H1N1/Swine Flu)**

Influenza is a viral infection that attacks the respiratory system (i.e., nose, throat, and lungs). Influenza viruses travel through the air in droplets when someone with the infection coughs, sneezes or talks. Influenza is transmitted either by inhaling virus-laden droplets directly, or by coming into physical contact with an object (e.g., telephone or computer keyboard) and then transferring the virus to the eyes, nose or mouth. People with the virus are likely contagious from about a day before symptoms appear until about five days after symptoms begin.

Common signs and symptoms of the flu include: fever, aching muscles, hills and sweats, headache, dry and persistent cough, shortness of breath, tiredness and weakness, runny or stuffy nose, sore throat, and eye pain. (Vomiting and diarrhea are also influenza signs and symptoms, but these are more common in children than in adults.)

Influenza viruses are constantly changing, with new strains appearing regularly. As a result, antibodies against influenza viruses that have been encountered in the past may not offer protection from new influenza strains, as the new strains can be very different viruses from previous strains.\(^8\)

**H1N1 Flu (Swine Flu)**

The H1N1 flu, commonly known as swine flu, is a type of influenza A virus and is one of several flu virus strains that can cause the seasonal flu. It is primarily caused by the H1N1

---

strain of the flu (influenza) virus. Symptoms of the H1N1 flu are the same as those of the seasonal flu.

The H1N1 virus is a combination of viruses from pigs, birds and humans that causes disease in humans. The virus enters your body when you inhale contaminated droplets or transfer live virus from a contaminated surface to your eyes, nose or mouth. It then infects the cells that line your nose, throat and lungs. 

**Tuberculosis**

Tuberculosis (TB) is a potentially serious infectious disease that mainly affects the lungs. Tuberculosis is caused by bacteria that spread from person to person through microscopic droplets released into the air. This can happen when someone with the untreated, active form of tuberculosis coughs, speaks, sneezes, spits, laughs or sings.

Although tuberculosis is contagious, it's not easy to catch. It is more likely for someone to get tuberculosis from a close family member or coworker than from a stranger. Most people with active TB who have had appropriate drug treatment for at least two weeks are no longer contagious. Many strains of tuberculosis resist the drugs most used to treat the disease. People with active tuberculosis must take several types of medications for many months to eradicate the infection and prevent development of antibiotic resistance.

**Norovirus**

Norovirus is a highly contagious virus commonly spread through food or water that is contaminated by fecal material during food preparation or by contaminated surfaces. Specifically, this virus can be transmitted through consuming contaminated food, drinking contaminated water, and touching one’s hand to one’s mouth after the hand has been in contact with a contaminated surface or object.

Norovirus can also be transmitted through close contact with an infected person.

Norovirus infections occur most frequently in closed and crowded environments such as hospitals, nursing homes, child care centers, schools and cruise ships. Noroviruses are difficult to kill off because they can withstand hot and cold temperatures and most disinfectants.

Symptoms such as diarrhea, stomach pain and vomiting typically begin 12 to 48 hours after exposure, and usually last one to three days. Most people recover from norovirus completely without treatment. However, for some people — especially infants, older

---

adults and people with underlying disease — vomiting and diarrhea can be severely dehydrating and require medical attention.\textsuperscript{11}

**Mumps**

Mumps is a viral infection that primarily affects saliva-producing (salivary) glands that are located near the ears. Mumps can cause swelling in one or both of these glands, and is contracted by breathing in saliva droplets from an infected person who has just sneezed or coughed. Mumps can also be contracted from sharing utensils or cups with someone who has mumps.

Complications of mumps, such as hearing loss, are potentially serious but rare. There’s no specific treatment for mumps.

Mumps outbreaks far less common than they used to be, but can affect people who aren't vaccinated – especially in close-contact settings such as schools or college campuses.\textsuperscript{12}

**E. Coli**

Escherichia coli (E. coli) bacteria normally live in the intestines of healthy people and animals. Most types of E. coli are harmless or cause relatively brief diarrhea. But a few strains, such as E. coli O157:H7, can cause severe stomach cramps, bloody diarrhea and vomiting. The E. coli O157:H7 strain belongs to a group of E. coli that produces a powerful toxin that damages the lining of the small intestine. Potential sources of exposure to E. coli O157:H7 include contaminated food or water – especially raw vegetables and undercooked ground beef – and person-to-person contact.

Signs and symptoms of E. coli O157:H7 include diarrhea (which may range from mild and watery to severe and bloody), stomach cramping, pain or tenderness, and nausea and vomiting. Infection can occur anytime from one day to one week after exposure to the bacteria, but usually begin three or four days after exposure.\textsuperscript{13}

**Sexually Transmitted Diseases (STDs)**

Sexually transmitted diseases (STDs) are generally acquired by sexual contact. STDs can be caused by: bacteria (gonorrhea, syphilis, chlamydia), parasites (trichomoniasis), or viruses (human papillomavirus, genital herpes, HIV). The organisms (bacteria, viruses or parasites) that cause STDs may pass from person to person in blood, semen, or vaginal and other bodily fluids. Sometimes STDs can be transmitted non-sexually, such as from mother to infant during pregnancy or childbirth, or through blood transfusions or shared needles.

STDs can have a range of signs and symptoms, including: sores or bumps on the genitals or in the oral or rectal area, painful or burning urination, pain during sex, soreness or discharge in genital areas, sore, swollen lymph nodes, particularly in the groin but sometimes more widespread, fever, lower abdominal pain, or rash over the trunk, hands or feet. Signs and symptoms may appear a few days after exposure, or it may take years before any noticeable problems occur, depending on the organism. STDs don't always cause symptoms, and may go unnoticed until complications occur or a partner is diagnosed.14

Location of the Hazard

Communicable diseases have the potential to affect the entire CSU planning area equally. As a result, the communicable disease hazard can be found at all the twenty-three (23) California State University (CSU) System campuses, at the CSU Office of the Chancellor, and at all CSU-owned satellite campuses, remote agricultural research, coastal research, and recreational facilities, and off-campus conference spaces. 15

Table CD.3 shows the locations of all CSU campuses and affiliated facilities. Because of the ubiquitous nature of communicable diseases, all of these locations are vulnerable to communicable disease hazard. As a result, students, faculty, staff at (and visitors to) all CSU campuses and affiliated facilities are at risk of exposure to the communicable disease hazard.

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. Table CD.4 shows the number of students that were living in CSU-campus-owned housing in Fall, 2019, prior to the COVID-19 pandemic.

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. The communicable disease hazards identified CSU campuses fall into Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 3-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases. Figure 3-1: Biosafety Levels (BSLs)21

The Extent of CSU System-Wide Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Meningitis, Measles, Influenza, Tuberculosis, Norovirus, Mumps, E. Coli, and Sexually Transmitted Diseases (STDs) reported at campuses throughout the CSU system. Five (5) of the non-COVID communicable diseases reported at CSU campuses – Meningitis, Measles, Norovirus, Mumps, and E. coli – would each be classified at the BSL-2 containment levels. Three (3)

of the communicable diseases – Influenza, Tuberculosis, and STDs would be classified at either the BSL-2 or BSL-3 containment levels. COVID-19 is classified at the BSL-3 containment level. 22 23

The Extent of CSU System-Wide COVID-19 Communicable Disease Hazard:

There is a considerable amount of data on the extent of COVID-19 throughout the CSU system. Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 5,165 cases of COVID-19 across all CSU campuses. CSU campus-specific COVID-19 case data can be found in the History of the Hazard section below. As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment and is therefore classified at BSL-3. For the planning committee, this level corresponds to a High extent ranking for the CSU 23-campus system. Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 3-4 below.)

With the exception of COVID-19, there is variability among CSU campuses regarding which communicable diseases have had the greatest impact on individual campus communities. Table CD.2 shows the communicable disease hazards that have had the greatest impact on each CSU campus.

History of the Hazard

Each CSU campus is an integral part of the surrounding community. Any event that occurs on a CSU campus has an effect on both the adjacent areas of campus and on the community-at large – and vice-versa. Communicable disease hazard events are no exception. Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Data limitations preclude providing the history or case data of non-COVID-19 communicable diseases at CSU campuses. However, the history of COVID-19 is well documented for the CSU system and for the State of California. Table below shows COVID-19 case data for CSU system campuses and for the State of California, respectively. These data have been extracted from a wide variety of CSU campus websites, and all CSU campuses except CSU San Bernardino and the CSU Chancellor’s office have been able to provide COVID-19 case numbers. CSU COVID Case Reports are updated on a weekly basis. Each CSU campus provides its own definition of a “case,” and COVID-19 case reporting start dates vary across CSU campuses. COVID-19 case data for CSU Bakersfield are in the table below.

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics have (and will continue to have) direct impact on life, health, and safety across the CSU system. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of CSU campus populations contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and

---

could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 3-8: WHO Risk Group Categorization\textsuperscript{26}

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table below describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall into these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is

important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases that fall under the higher-risk RG3 category. However, with the advent of the recently developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 3-9: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one’s hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

### RG 3

<table>
<thead>

<td></td>
</tr>
<tr>
<td>Hantaviruses</td>
<td></td>
</tr>
<tr>
<td>Avian Flu</td>
<td></td>
</tr>
</tbody>
</table>

These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

### RG 4

<table>
<thead>
<tr>
<th>H5N1 (Bird Flu)</th>
<th>Dengue Hemorrhagic Fever</th>
</tr>
</thead>
<tbody>
<tr>
<td>Marburg Virus</td>
<td>Ebola Virus</td>
</tr>
<tr>
<td>Smallpox</td>
<td>Lassa Fever</td>
</tr>
<tr>
<td>Crimean-Congo Hemorrhagic Fever</td>
<td>Other Hemorrhagic Diseases</td>
</tr>
</tbody>
</table>

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

### Probability of Future Occurrence of the Hazard

There have been cases of a variety of communicable disease throughout the CSU system, including COVID-19 (SARS-CoV-2), Meningitis, Measles, Influenza (Including H1N1/Swine Flu), Tuberculosis, Norovirus, Mumps, E. Coli, and Sexually Transmitted Diseases (STDs). However, there are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.
The following table shows an annual probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 3-10: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence. It is important to note here that a communicable disease can be rated as having a probability of future occurrence CSU-system-wide that is different from that at the individual CSU campus level.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at CSU campuses.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, the CSU System had 480,541 students and 53,763 faculty and staff.) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic.

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU

28 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx
29 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
campuses are at risk of developing an extreme incidence of COVID-19 and may become “super-spreaders” for adjacent communities.\(^\text{30}\) The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. Several CSU campuses saw refund losses surpass $10 million.

Figure 3-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs\(^\text{31}\)

![Figure 3-2: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs](https://calmatters.org/wp-content/uploads/2020/08/July-summary.pdf)

During Spring Semester, 2020, campus shutdowns, the shift to remote learning, shrinking revenue from sources like dorm fees and student bookstores, and changes in enrollment patterns across the system unrelated to COVID-19 all hit the California State University

---

system simultaneously with well over a $300 million loss from reduced revenues and from new costs.

While there has been a more recent surge in enrollment at CSU campuses during Fall Semester, 2020, the loss of future tuition and fee revenue due to COVID-19 is not yet known, as resident enrollment patterns are not yet fully understood by individual campuses. However, it is expected that non-resident and international student enrollments could be down by at least one-third compared to their pre-pandemic enrollment levels.

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table CD.10) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Vulnerability Assessment Conclusions

Before the COVID-19, pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity. At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.
Another potential vulnerability for the CSU system is highly decentralized nature of the CSU system itself. The 23-campus CSU system maintains facilities located within twenty-six (26) local Health Department jurisdictions. Some individual CSU campuses have facilities located within the jurisdictions of three (3) different local health departments. As a result, well-integrated and coordinated communicable disease mitigative measures across the CSU system are challenging and may prove both cumbersome and unfeasible. The following table shows the local Health Department jurisdictions under which each CSU campus falls.

Table 3-14: Local Health Department Jurisdictions for CSU Campuses.

Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).
**Dam and Levee Failure**

**Description of the Hazard**

Dam failure is the uncontrolled release of impounded water from behind a dam. Flooding, earthquakes, blockages, landslides, adverse geological conditions, lack of maintenance, aging infrastructure, improper operation, poor construction, vandalism, and terrorism can all cause dam failure. Dam failure from overtopping is a specific failure mechanism resulting from inadequate spillway capacity or other spillway issues and seiches. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

Dam failures are most likely to happen for one of the following reasons:

- **Overtopping** - caused by water spilling over the top of a dam. Overtopping of a dam is often a precursor of dam failure.
- **Foundation Defects** - including settlement and slope instability, cause about 30% of all dam failures.
- **Cracking** - caused by movements like the natural settling of a dam.
- **Inadequate maintenance and upkeep.**
- **Piping** - is when seepage through a dam is not properly filtered and soil particles continue to progress and form sink holes in the dam.

National statistics show that overtopping due to inadequate spillway design, debris blockage of spillways, or settlement of the dam crest account for approximately 34% of all U.S. dam failures. Dam failure from overtopping can occur when the inflow volume into a reservoir (primarily caused by stormwater runoff) exceeds the volume of water that can be stored and evacuated from a reservoir via its spillway. 20% of all U.S. dam failures have been caused by piping (internal erosion caused by seepage). Seepage often occurs around hydraulic structures, such as pipes and spillways; through animal burrows; around roots of woody vegetation; and through cracks in dams, dam appurtenances, and dam foundations.³⁸

**Location of the Hazard**

A jurisdictional dam in California has a height greater than six feet while impounding 50 acre-feet or more or a height greater than 25 feet with storage capacity of 15 acre-feet or more. As of early 2018, there are more than 1,537 dams of jurisdictional size in California. Approximately 1,250 of these dams are under jurisdiction of the California Department of Water Resources (DWR), Division of Safety of Dams (DSOD),

³⁸ https://damsafety.org/dam-failures
and approximately 287 dams owned by federal government agencies. Los Angeles County leads the state with 91 jurisdictional dams, followed by Sonoma County with 64 dams. Del Norte County is the only county in the state that has no dams of jurisdictional size. Please refer to each campus Annex for the locations of dams relative to each campus.

Figure 3-4: Dams located in the State of California

Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure. The DWR Division of Safety of Dams (DSOD) reviewed the hazard classification of all its dams and sub-divided the high hazard classification into two classifications: High Hazard and Extremely High Hazard.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses. 
- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and

---

39 State of California. Division of Dam Safety. Retrieved on 03.31.2021 from: https://water.ca.gov/Programs/All-Programs/Division-of-Safety-of-Dams
specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

Note: Please refer to the annex for each campus for a listing and ranking of high hazard dams in the vicinity of the campus.

For the CSU system as a whole, some campuses are located within the inundation zone while the majority of campuses are located outside of it. In the event of catastrophic failure of a given dam, some campuses will experience indirect impacts such as disruption of transportation routes, while others will experience direct impacts damaging assets, threatening life and a total shut-down of all campus operations. Based on these wide-ranging conditions, the CSU system-wide planning committee ranks the extent of dam failure overall as Moderate.

History of the Hazard

Since 1929, the State of California has regulated dams to prevent failure, safeguard life, and protect property. The California Water Code entrusts dam safety regulatory power to DWR, Division of Safety of Dams (DSOD). DWR provides oversight to the design, construction, and maintenance of over 1,200 jurisdictional sized dams in California.

In the past 50 years, there have been only a small number of dam failures in California. The most catastrophic dam failure in California’s history is that of the infamous St. Francis Dam in Los Angeles County, which failed in March 1928, shortly after construction of the dam was completed. This failure resulted in the deaths of more than 450 people and the destruction of nearly 1,000 homes and buildings. Numerous roads and bridges were also destroyed or damaged beyond repair. It was a landmark event in the history of state dam safety legislation, spurring legislation not only in California, but in neighboring states as well. The Division of Safety of Dams (DOSD) was established as a direct result of this catastrophe. Other significant dam incidents in California’s history include the Baldwin Hills Dam failure in 1963, the near failure of the Lower San Fernando Dam in 1971, and the failure of the spillway system at Oroville Dam in 2017.

Note: Please refer to each campus Annex for any historical occurrence of dam failure relative to the campus’ location. Data indicate that minor dam failures have occurred in a small minority of communities where CSU campuses are located. However, based on best available data, no dam failure events directly impacting a CSU campus have taken place.
Potential Impacts of the Hazard

Dam failures have the potential to cause immense property and environmental damages and take lives. Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

As the state’s dams age and population increases, the potential for deadly damage failures grows. The American Society of Civil Engineers’ 2017 Infrastructure Report Card reported that dam failures not only risk public safety, they also can cost the economy millions of dollars in damages. Failure is not just limited to damage to the dam itself. It can result in the impairment of many other infrastructure systems, such as roads, bridges, and water systems. When a dam fails, resources must be devoted to the prevention and treatment of public health risks as well as the resulting structural consequences.40

Probability of Future Occurrence of the Hazard

With a changing climate that includes an expectation of increased extreme weather events in California, including prolonged periods of severe drought and intense wet periods with less snowpack and degraded conditions in source watersheds, dam operation and maintenance becomes more difficult and the risk of spillway activation and dam failure from overtopping may increase. However, given current monitoring and maintenance protocols are highly regulated and adaptive by nature, the system-wide planning committee ranks the probability of occurrence as Possible.

Vulnerability to the Hazard

The DWR Division of Safety of Dams (DSOD) reviewed the hazard classification of all its dams and sub-divided the high hazard classification into two classifications: High Hazard and Extremely High Hazard. As of August 2017, there are 1,249 dams under state jurisdiction, of which 474 are High Hazard and 196 are Extremely High Hazard (670 High Hazard per FEMA definitions). Remediation needs at this time have been identified at 97 dams, of which 60 are High or Extremely High Hazard.

DSOD engineers inspect over 1,200 dams on a yearly schedule to ensure they are performing and being maintained in a safe manner. The DSOD also periodically reviews the stability of dams and their major appurtenances in light of improved design approaches and requirements, as well as new findings regarding earthquake hazards and hydrologic estimates in California.

According to FEMA, most people living downstream of a dam are unaware of the potential hazards associated with dam failure, have never seen the respective dam failure inundation map, and are unaware of an evacuation plan or an EAP associated with the failure of that dam.

That said, given that most CSU campuses lie outside of dam inundation zones, and that highly regulated dam monitoring, inspection and maintenance practices are in place, a catastrophic dam or levee failure is highly unlikely. However, in the unlikely event of a dam failure somewhere within a CSU-located community, the effects of flooding on campus would most likely be limited to indirect or secondary effects in terms of disruption to local or regional transportation networks utilized by the campus community and a disruption of campus operations and services.

Certain campus populations will experience greater challenges to a post-dam failure environment. During low probability, extensive dam failure events, vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. In addition, even with minor flooding, the potential for flood damaged structures being left uninhabitable is possible, including campus residence halls on the minority of campuses located within dam inundation zones.

Estimate of Potential Losses

Estimates of potential losses for those campuses at risk will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties.
Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Vulnerability Assessment Conclusions

Although the occurrence of dam failures has historically been limited throughout the state, the potential for failures related to the region’s levees and dams still exists. The presence of earthquake faults in proximity to many state dams presents a significant risk to dam structure in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences would generate catastrophic results to downstream communities. The proximity to the rivers and the levees providing a barrier between the campus and the rivers further presents a hazard facing campus at risk. The potential for dam or levee failure generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular segments of campus communities including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Although we know which factors produce variability in the degree of dam failure risk and potential economic loss from one campus to another, quantifying dollar losses is currently limited and will require a HAZUS analysis or other type of analysis at the campus level and CSU system-wide. The CSU system’s leadership may consider developing such data sets in the future.

Levee

Description of the Hazard (Levee)

Levees in California protect land from peak flood levels and/or protect land that is below sea-level. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water.[1] Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Examples are the levees along the Russian River or the Sacramento River near Sacramento. The second type of levee is intended to withstand nominal water levels on a continuous basis as well as peak flood levels. Examples are the levees throughout Sacramento-San Joaquin Delta. The Bay-Delta is a complex system in which there are three rivers bring in fresh water and tidal fluctuations cycle in salt water or brackish water.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levee failures can vary from over toppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to
inundation dependent on the volume of water released. These levee failures are also
typically the result of structural age, damage to the structure caused by earthquake or
flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee,
inadequate capacity, inadequate maintenance, improper construction materials, or
extreme inflow of water into the system. Flood damage resulting from levee failures
potentially will result in economic losses, environmental damage, destruction of
agriculture, and human casualties.

Six main failure mechanisms are a function of the three loading functions. The six
mechanisms are bearing failure, sliding failure, slump or spreading failure, seepage
failure, erosion failure, and overtopping, which may be described as follows:

- A bearing failure in levees is typically deep-seated and can be induced by seismic
ground shaking or a loss of soil shear strength. Failure can be triggered by a
seismic event that either causes a loss of soil strength or produces destabilizing
inertial loading conditions.
- A sliding failure may occur if the foundation soil has a weak or brittle zone
resulting in a preferred failure plane. Both seismic-induced inertial loading and
high-water levels can cause sliding failures.
- Slumping and spreading can be generated by two loading conditions. Cyclic
loading from earthquakes may generate increased pore pressures and reduced soil
strength, leading to volumetric and/or deviatoric strains in the foundation. The
same results can also occur due to increased pore pressures from high water
levels and increased seepage.
- Seepage is one of the most common failure mechanisms in levees. Levees are
built in fluvial depositional environments, and it is common to find levees with an
existing sandy layer beneath the foundation. The sandy layer can be a conduit for
flow underneath the levee, resulting in critical conditions at the landside toe of the
levee. This can lead to erosion of the foundation during high water or a consistent
weakening of the foundation over a long period of time, both eventually leading to
failure. Biogenic agents can also lead to destabilizing seepage. These can include
rodent holes, tree roots, or other biological activity that create conduits for
seepage. Some of the materials used in the construction of levees historically are
also susceptible to through seepage. This through seepage can also result in a
failure.
- High-velocity flows can erode material from the outboard or waterside of the
levee, which may lead to instability and failure. Erosion can occur at once or over
time as a function of the storm cycle and the scale of the peak storms.
- The failure mechanism of overtopping occurs when high water exceeds the
elevation of the levee crest. The water energy is then concentrated at the landside
toe of the levee, leading to soil erosion and decreased levee stability. Once
overtopping starts, the erosion can quickly lead to a large failure. Some areas in
California have experienced land subsidence due to groundwater depletion or
other reasons. Land subsidence can cause overtopping to occur in areas that have
not had overtopping risk in the past.
Location of the Hazard

Most levees in California are in the Bay-Delta and, for the most part, protect land that is at or below sea-level. There are vast areas in the Delta that are already below sea-level. The Bay-Delta is a complex system in which there are three rivers bring in fresh water and tidal fluctuations cycle in salt water or brackish water. In addition to facing risks to its water system from Delta levee failures, the Bay Area also has numerous substandard levees protecting both low-lying and below-sea-level urban areas and infrastructure, including the Oakland International Airport. That said, neither CSU campus in the Bay area (CSU-East Bay and San Francisco State) are located within a levee protected inundation zone. In addition, only 6 of the 23 CSU campuses lie within a levee protected inundation zone.

Extent of the Hazard

Ground shaking in and around levees resulting from earthquakes 100 kilometers or more away can affect levee performance. The type of foundation the levee is constructed upon (such as peat or alluvium) will influence a levee’s performance during a seismic event or under certain static loading conditions.

Millions of people and billions of dollars of assets in California are protected by levees. Levees in California protect land from peak flood levels and/or protect land that is below sea-level. The first type of levee is intended to withstand peak flood levels that are caused by intense rainfall or rapid snow melt within the watershed. Examples are the levees along the Russian River or the Sacramento River near Sacramento. The second type of levee is intended to withstand nominal water levels on a continuous basis as well as peak flood levels. Examples are the levees throughout Sacramento-San Joaquin Delta. The San Francisco Bay-San Joaquin-Sacramento Delta region (a.k.a. “the Delta” or “the Bay-Delta”) contains levees critical for delivering irrigation water to 3 million acres and drinking water to over 23 million people. A failure in one of the Delta levees in 1972 interrupted the state and federal water supply systems and required approximately 500,000 acre-feet of fresh water to restore export water to acceptable quality. Recent studies indicate the levees in the Delta are susceptible to damage from close or more distant seismic events.

Some of the areas protected by these levees were originally intended to have land use compatible with agriculture but have subsequently become urban. Some of the levees in California have been augmented in recent years but many remain as originally constructed or have deteriorated. Changes in climate affecting hydrologic patterns in California, as well as sea-level rise, are bringing additional loading to levees.

With the reclaimed floodplains not being replenished with new sediment and the drying out of some of the boggy areas, the land protected by the levees began to drop in elevation via subsidence and wind erosion of topsoil. Land behind the levees will continue to drop in elevation with the addition of potential sea-level rise exacerbating the situation.
DWR is evaluating and upgrading aging and deteriorating levees along the Sacramento River and San Joaquin River valleys and the Delta. To expedite efforts to protect these communities, levee evaluations were conducted in a fast-track manner over an eight-year period. To date, nearly 250 levee repair sites have been identified, with more than 100 of the most critical sites having already been repaired. Repairs to others are either in progress or scheduled to be completed in the near future, and still more repair sites are in the process of being identified, planned, and ranked.

FOR CSU system-wide, levees are located along numerous irrigation channels and other waterways surrounding six (6) campuses in part or in whole, and, as such, lie in levee protected areas, and are, to varying degrees, vulnerable to levee failure. Said campuses include Bakersfield, Channel Islands, Chico, Northridge, Sacramento and San Bernardino. And all six maintain a Moderate extent ranking for levee failure. For campuses at greatest risk, levee failure could substantially alter the ability of the given campus to maintain operations as damages would be extensive. Depending on the location of a breach, the campus community would be heavily affected with the loss of life and homes, access to campus would be limited, and student financial capacity to support ongoing education being diminished.

The remaining 17 campuses are not located within such areas and are not at risk or vulnerable to direct impacts from levee failure, though they may experience indirect effects such as transportation route disruption. Based on these wide-ranging sets of conditions, the planning committee ranks the overall extent of the levee failure hazard system-wide as Low to Moderate.

History of the Hazard

When the levees began being constructed in California’s Central Valley in the 1850s to protect or claim floodplains including islands in the Delta, for agricultural purposes, soil was either scraped from adjacent land or dredged from adjacent channels and placed onto existing natural levees. The soil generally made poor foundation material for levees. During the same time period, hydraulic mining occurred in the mountains at the headwaters of the rivers that feed the Delta and huge amounts of sediment were flushed downstream raising riverbeds and causing increased flooding. To prevent buildup of this sediment, levees were built and/or heightened to increase flows through the low-lying areas to aid in moving the sediment pulses through the Delta.

The levees have been augmented since then to produce the current system. After several devastating floods the U.S. Army Corps of Engineers (USACE) started modifying and constructing levees as early as the early 1900s using sediment from adjacent rivers and channels. Levees were also constructed by others in the 1900s in areas subject to coastal influences, such as in San Francisco and San Pablo Bays. Until about the 1940s to 1950s, most levees were not engineered and frequently failed. Some of the levees in California have been augmented in recent years but many remain as originally constructed or have deteriorated. Changes in climate affecting hydrologic patterns in California, as well as sea-level rise, are bringing additional loading to levees.
With the reclaimed floodplains not being replenished with new sediment and the drying out of some of the boggy areas, the land protected by the levees began to drop in elevation via subsidence and wind erosion of topsoil. Land behind the levees will continue to drop in elevation with the addition of potential sea-level rise exacerbating the situation.

California voters have approved billions of dollars in bonds over the years to finance various critical infrastructure improvements and retrofit projects. A November 2006 bond election resulted in provision of $4.9 billion of levee repair and improvement funding. The 2006 levee bond election led to formation of the California Department of Water Resources (DWR) Delta Risk Management Strategy (DRMS) program and to initiation of a comprehensive flood mitigation program in the Central Valley. Additionally, the Delta Stewardship Council was created to lead a multi-agency effort to update priorities for state investments in the Delta levee system. The Delta Levees Investment Strategy (DLIS) released in 2017 updated priorities for state investments in the Delta levee system to reduce the likelihood and consequences of levee failures and to protect people, property, and state interests. Overall, no CSU campuses have experienced a levee failure impact.

Potential Impacts of the Hazard

The type of foundation the levee is constructed upon (such as peat or alluvium) or the composition of the levee itself (such as loose sand) will influence a levee’s performance during a seismic event or under certain static loading conditions. Many levees in the Delta are designed nominally to 100-year design flood levels. In parts of California, both the chances and the consequences of flooding are ranked the highest in the nation. Many of the levees in California are intended to protect against a storm related flood event with a 1 percent chance of occurring in any year. Some areas have an even lower level of protection.

As an example, Sacramento-San Joaquin Delta Levees failures would likely stop the export of Delta water until water quality is restored. Approximately 60 percent of the water supply of the San Francisco Bay Area is extracted from or passes through the Delta. The intrusion of saltwater would force the State of California and Bureau of Reclamation to stop pumping and would endanger the water supply for 3 million acres of irrigated land and over 23 million people. A levee failure would result in an encroachment of brackish or seawater into the Delta. The presence of the saltwater would also have a significant impact on local agriculture and salt-sensitive native species.

In general, a levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on several factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:
- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community
- Hazardous/toxic material impacts
- Disruption of evacuation routes

**Probability of Future Occurrence of the Hazard**

The California Water Policy Council and Federal Ecosystem Directorate (CALFED's “Seismic Vulnerability of the Sacramento-San Joaquin Delta Levees” report of April 2000 concluded that 3 to 10 failures are likely to occur on critical Delta levees during an earthquake with a 1 percent chance of occurring in any year (100-year level of protection).

Climate change in California is expected to increase the risk of flooding significantly. Increased flood frequency and magnitude are predicted consequences of climate change. As annual temperature increases more of the precipitation that would have fallen into the mountains as snow may fall instead as rain, increasing winter flows in the rivers downstream into the Delta system. As sea-levels rise, flood stages also rise, putting increasing pressure on levees. This threat may be particularly significant because recent estimates indicate that the additional force exerted upon the levees is equivalent to the square of the water level rise. For example, estimates using historical observations and climate model projections suggest that extreme high-water levels in the Bay and Delta will increase markedly if sea-level rises above its historical rate. These extremes are most likely to occur during storm events, leading to more severe damage from waves and floods. As water levels in the Delta increase, water levels upstream in the Sacramento and San Joaquin Rivers will also increase, putting additional pressure on levees located there.
That said, the probability of occurrence is tied to the extent to which such data and analysis of current conditions lead to a proactive and effective set of inspection, monitoring, maintenance, and improvement/mitigation measures. For the communities where CSU campuses are located, such measures and protocols are in place and are highly regulated. As such, the planning committees unanimously rank the probability of levee failure as Unlikely.

Vulnerability to the Hazard

The stability of levees is a function of several variables. Three main loading functions related to levee failure are water level changes, ground shaking, and static loading. Water level changes can be due to peak flood levels or rapid drawdown; both are known to adversely affect the stability of levees. Other hydrostatic influences known to affect levee stability are constant load, cyclical influx of seawater from bay (tidal changes), and reverse flows in some areas. Ground shaking is a function of earthquakes in and around the levees but can occur up to 100 kilometers or more away and still affect levee performance. Static loading represents the nominal loading conditions that regularly exist, but documented levee failures have occurred with no adverse conditions other than static loading.

However, as previously discussed, both the stability of the levee and the related vulnerability of downstream communities are a function of the extent to which proactive and effective sets of inspection, monitoring, maintenance, and improvement/mitigation measures are in place. For the communities where CSU campuses are located, such measures and protocols are in place and are highly regulated. For the CSU system, 6 of 23 campuses lie within highly regulated levee protected areas. As such, the vulnerabilities and impacts tied to a catastrophic levee failure as discussed within each campus Annex should regarded as extremely remote population and asset exposures.

Estimate of Potential Losses

Millions of people and billions of dollars of assets in California are protected by levees. The consequences of the levee failures is in terms of dollar figures associated with crop loss, building destruction, life loss, or saltwater intrusion that brings to a halt the pumping of fresh water to Central and Southern California as well as potential for environmental losses. Some of the areas protected by levees were originally intended to have land use compatible with agriculture but have subsequently become urban.

Vulnerability Assessment Conclusions

Earthquakes and high water are two of the greatest geo-physical risks to levees. The levee failure mechanism resulting from an earthquake deemed most likely was liquefaction of sand with levee fills if ground motions are sufficient. In addition, with climate change, floods and winds are projected to become more severe. A combination of higher tides, wind-driven surges, and high river discharge creates a significant high-water threat to levees. Offsetting geo-physical risks is human intervention, including levee inspection,
monitoring, maintenance, and improvement/mitigation measures. Such measures are effectuated consistently across CSU-based communities. As such, catastrophic events and related vulnerabilities for CSU campuses are represent extremely unlikely worst case scenarios.

Identified Data Limitations

Although we know which factors produce variability in the degree of levee failure risk and potential economic loss from one campus to another, quantifying dollar losses is currently limited and will require a HAZUS analysis or other type of analysis at the campus level and CSU system-wide. The CSU system’s leadership may consider developing such data sets in the future.
**Drought**

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage at CSU’s 23 campuses across the state) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified in all of the municipalities, counties and regions wherein the 23 CSU campuses are located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout the planning area and across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire CSU planning area equally, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and types of activities, historically impacted by drought within each campus and surrounding community. For example, five (5) CSU campuses maintain agricultural programs with assets and products particularly vulnerable to drought (Cal Poly San Luis Obispo, Humboldt State, Fresno State, CSU-Chico, Cal Poly Pomona).

In addition, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Overall, based on the above

---

factors, the CSU planning committee ranks the extent of the hazard for its campuses as **Moderate**.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

42 United States Drought Monitor. *Drought Classification*. Retrieved 05.04.2021 from: [https://droughtmonitor.unl.edu/About/AbouttheData/DroughtClassification.aspx](https://droughtmonitor.unl.edu/About/AbouttheData/DroughtClassification.aspx)
Dairy operations close
Marijuana growers illegally tap water out of rivers
Fire season lasts year-round; fires occur in typically wet parts of state; burn bans are implemented
Ski and rafting business is low, mountain communities suffer
Orchard removal and well drilling company business increase; panning for gold increases
Low river levels impede fish migration and cause lower survival rates
Wildlife encroach on developed areas; little native food and water is available for bears, which hibernate less
Water sanitation is a concern, reservoir levels drop significantly, surface water is nearly dry, flows are very low; water theft occurs
Wells and aquifer levels decrease; homeowners drill new wells
Water conservation rebate programs increase; water use restrictions are implemented; water transfers increase
Water is inadequate for agriculture, wildlife, and urban needs; reservoirs are extremely low; hydropower is restricted
Fields are left fallow; orchards are removed; vegetable yields are low; honey harvest is small
Fire season is very costly; number of fires and area burned are extensive
Many recreational activities are affected
Fish rescue and relocation begins; pine beetle infestation occurs; forest mortality is high; wetlands dry up; survival of native plants and animals is low; fewer wildflowers bloom; wildlife death is widespread; algae blooms appear
Policy change; agriculture unemployment is high, food aid is needed
Poor air quality affects health; greenhouse gas emissions increase as hydropower production decreases; West Nile Virus outbreaks rise
Water shortages are widespread; surface water is depleted; federal irrigation water deliveries are extremely low; junior water rights are curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor;

History of the Hazard
Historically, drought has been so prevalent in California that its presence is almost ubiquitous and consistently recurring, including those communities connected to the
CSU 23-campus footprint. According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs. 43

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2-3 month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017. Please refer to each campus Annex for the Figure showing historical periods of drought for the county connected to each campus. Each Figure provides the county-level data corresponding to the state-level data in Figure 3-5 (below).

Figure 3-5: Periods of Drought in State of California, 2001 – 202144

Given the ubiquitous nature of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the communities surrounding the CSU 23 campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to homeowners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2014=2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent. 45

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant impact associated with drought across the CSU 23 campus planning area is the historic and potential reduction in water availability for the municipal area tied to each campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU campuses variably includes these vulnerable resources based on each campus’ landscape (trees) and the existence (and footprint size) of agricultural research crops and field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not

limited to such. However, the wildfire hazard is analyzed separately in this plan. (See X for coverage of the wildfire hazard).

In reviewing the occurrences of drought for CSU campus’ 23 locations (in municipalities and counties), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2014-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to the CSU system, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on-campus; however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.

At present, drought related damage to campus buildings and infrastructure has not been reported, but the potential for such impacts is possible.

With regard to overall potential impact, water supply/availability for CSU campuses is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU campuses. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Groundwater

Indirect

Reduction in snowpack and extended periods of drought are likely to increase dependency on groundwater

Probability of Future Occurrence of the Hazard

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that the CSU planning area covers 23 campuses spread throughout the state, it is prudent to extend this likelihood of occurrence to the planning area.

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. Given that state-level drought location, extent and potential impact frame these same factors at the level of the CSU campus system, these same state-level conditions apply to the vulnerability of the CSU system as well.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and CSU planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of one-to-two-million-acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. 49 In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

________________________

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

Vulnerability of Populations

The historical and potential impacts of drought on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerability measures apply to the students, faculty and staff of the CSU 23-campus system.

Property Vulnerability

The historical and potential impacts of drought on property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerability measures apply to the properties of the CSU 23-campus system.

Natural Environment Vulnerability

The historical and potential impacts of drought on the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping the impact of drought throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental

---

management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought impacts to state and CSU critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the CSU system as a whole. However, drought related losses to the cities, counties and regions surrounding each campus such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality. CSU leadership may acquire or produce such data sets in the future.
**Earthquake**

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** - The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** - As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur.

The severity of earthquake damage is expressed in terms of magnitude and intensity. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. (See Mercali Scales under Extent of the Hazard section below).

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. California has a chronic and destructive earthquake history with widespread vulnerability, as indicated by California
Geological Survey (CGS) mapping of potential earthquake shaking intensity zones. Many of these zones are commonly located near populated areas.
The state- and federal-declared earthquake disasters by county (representing 26 of California’s 58 counties) are:

- Los Angeles County – 6
- Imperial County – 5
- Humboldt, Napa, and Solano Counties – 3 in each county
- Orange, Riverside, San Bernardino, Santa Barbara, and Santa Clara Counties – 2 in each county
- Alameda, Butte, Contra Costa, Fresno, Marin, Modoc, Mono, Monterey, Sacramento, San Benito, San Francisco, San Joaquin, San Luis Obispo, San Mateo, Santa Cruz, Sonoma, and Ventura Counties – 1 in each county

52 CA Geologic Survey/2018 CA SHMP
The above map shows the distribution within California of state-proclaimed and federally declared earthquake disasters from 1950 to 2017. The distribution of disasters can be generally related to potential future earthquake shaking hazards levels in California.

**Extent of the Hazard**

Please consult each campus annex for those factors and conditions shaping the extent of the earthquake hazard, along with a corresponding extent ranking. Given a wide-range of extent factors and rankings across the CSU system, the system-wide planning committee ranks the extent of the hazard for the system as a whole as **Moderate**.
The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the extent or magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

History of the Hazard

California has a chronic and destructive earthquake history with widespread vulnerability, as indicated by California Geological Survey (CGS) mapping of potential earthquake shaking intensity zones. Many of these zones are commonly located near populated areas. Earthquakes large enough to cause moderate damage to structures—those around Magnitude 5.5—occur three to four times a year in California. Strong earthquakes of Magnitude 6 to 6.9 strike California on an average of once every two to three years. An earthquake of magnitude 6 to 6.9 strike California on an average of once every two to three years, such as the 1994 Northridge Earthquake (Magnitude 6.7) or the 1983 Coalinga Earthquake (Magnitude 6.7), is capable of causing major damage, if the epicenter is near a densely populated area. Major earthquakes (Magnitude 7 to 7.9) occur in California about once every 10 years. It is well established that earthquake monitoring and data gathering instruments detect earthquakes regularly in many of the communities connected to CSU campuses, and events “felt” by the population in these communities are not uncommon and occasionally occur. That said, the 1989 Loma Prieta earthquake in San Francisco and the 1994 Northridge earthquake are the two most notably catastrophic events.

Potential Impacts of the Hazard

Earthquakes represent the most destructive source of hazards, risk, and vulnerability, both in terms of recent state history and the probability of future destruction of greater magnitudes than previously recorded. Earthquakes are a significant concern for California. In addition to shaking, buildings are also vulnerable to ground displacements associated with primary fault rupture, liquefaction, differential settlement, and landslides. Inundations from tsunamis, seiches, and dam failures can also be major sources of loss to buildings and infrastructure. Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety.

The 1994 Northridge Earthquake (Magnitude 6.7) which caused over $40 billion of disaster losses, 57 deaths, and 11,846 injuries. After the Northridge earthquake, all the buildings at California State University, Northridge were closed. Through the dedication of the administration the campus reopened for classes one month later—using 450 trailers and other temporary buildings spread around on available campus space.54

During an earthquake event, CSU campuses impacted may experience closures of different kinds of campus spaces, including classrooms, laboratories, libraries and offices. In addition to the potential loss of life, buildings and infrastructure, there are a wide range of additional value losses, including equipment, building contents, and scholarly and

scientific research. The trauma associated with experiencing a large earthquake often requires mental health assistance to victims.

The impacts of a major earthquake would be felt beyond any given campus and would have long reaching effects. The risk of casualties and damages would likely extend to the homes and workplaces of members of the campus community including students, staff, and faculty. The effects on the regional economy may be negatively altered as commercial and industrial facilities may not be functional due to damaged goods and/or facilities. The cessation of businesses would result in job losses and greater needs among members of the community. Ability to rebuild will be influenced by the disrupted supply chain and contractor resources, affecting the continuity of operations on the campus and impacting the educational productivity and return of students whose education is disrupted. Short-term closures will impact the retention of the students, and potential recruitment of faculty.

Please note that the (above) earthquake impacts might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events.

In summary, potential impacts to CSU campuses from an earthquake could include:

- Potential hazardous material releases on and off campus
- Infrastructure damage to State Route 99
- Damages to rail lines and rail cars ½ mile to east and west of campus
- Structural damage to bridges over waterways and flood control channels
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to flood control levees
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences and businesses
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

For the state’s two most densely populated metropolitan areas, based on the most recent earthquake forecast model for California, the USGS and other scientists estimate a 72-
percent probability that at least one earthquake of Magnitude 6.7 or greater, capable of causing widespread damage, will strike the San Francisco Bay Area before 2044. For the Los Angeles region, the same model forecasts a 60-percent probability that an earthquake of Magnitude 6.7 or greater will occur before 2044.

The map below depicts probabilities of various magnitude earthquakes greater than Magnitude 6.7 occurring in 30 years in various regions of the state. These probabilities include greater than 99 percent for a Magnitude 6.7 event, 93 percent for a Magnitude 7.0 event, 48 percent for a Magnitude 7.5 event, and 7 percent for a Magnitude 8.0 event. Given the location of CSU campuses in relation to the fault lines described in each campus annex along with their locations in relation to the magnitude/probability map (below), the system-wide planning committee ranks the probability of occurrence for the system as a whole as Possible to Likely.
Vulnerability to the Hazard

The CSU campuses located in areas identified as earthquake intensity zones are susceptible to earthquake impacts. The degree of earthquake resilience will be based on the conditions of the individual buildings, the level of seismic strengthening (structural and non-structural retrofitting) and the number of buildings that have been designed and built to a higher standard of earthquake safety. The building damage will vary, depending on the campus location in context of the earthquake epicenter and the duration and direction of the ground motions. Observations of damage from California earthquakes have also shown that ground shaking may be locally attenuated but then be amplified farther away due to differential soil conditions and structural response.

In addition to building and population vulnerabilities, campuses may be vulnerable to an earthquake due to local and regional impacts on the following infrastructure:

- Electrical utilities
- Pipeline networks: oil and natural gas
- Petrochemical facilities: oil refineries and liquefied natural gas facilities
- Localized water and wastewater pipelines and treatment facilities
- Statewide water system: aqueducts, canals, levees, dams, and reservoirs
- Solid waste disposal systems
- Transportation systems
- Ports and harbors
- Communication systems
- Hospital and Heath Care facilities

**Estimate of Potential Losses**

Estimates of potential losses for each campus will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions. The CSU leadership may consider conducting an advanced analysis of quantitative/dollar loss impacts to each campus and for the system as a whole in the future.

**Vulnerability Assessment Conclusions**

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the CSU campuses. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. For campuses at risk, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU campus and community.

In the event that a major earthquake was to strike along the fault systems, the effects could be significant to the campus community and campus operations.

Compared to other earthquake vulnerabilities, CSU buildings pose the largest risk to life, injury, property, and economic welfare. The buildings built to earlier standards may have inadequate earthquake performance. Observations after earthquakes indicate that building safety is most often compromised by poor quality in design and construction, inadequate maintenance, lack of code enforcement at the time of original construction, and improper alterations to the original building.

A less common cause of damage is the poor performance of older buildings built to earlier seismic codes. Explicit requirements for earthquakes first began to be incorporated into building codes in 1933 and the state first required local governments to create building departments and issue permits. The Structural Engineers Association of California’s first statewide consensus on recommended earthquake provisions were published in 1960. In the mid- to late-1970s significant improvements to lateral force requirements began to be enforced throughout the state. California did not have uniform adoption of the same edition of model codes in every jurisdiction until the early 1990s.

Nonstructural building components on CSU properties can also become vulnerable to damage during earthquakes. Ceilings, air conditioning equipment, plumbing and water heaters, windows, chimneys, appliances, and stone veneer are examples of non-
structural components that may become damaged as a result of earthquake ground shaking.

While ground shaking may be the predominant agent of damage in most earthquakes, fires following earthquakes can also lead to catastrophic damage depending on the combination of building characteristics and density, meteorological conditions, and other factors. Fires following earthquakes may result from multiple causes (e.g., overturned burning candles, electrical sparking from downed power lines, and broken natural gas pipelines). 56

The widespread impacts generated by a major earthquake impacting a CSU campus would extend the effects of casualties, damages, and other impacts to the broader campus region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources.

Identified Data Limitations

Although we know which factors produce variability in the degree of earthquake risk and potential economic loss from one campus to another, quantifying dollar losses is currently limited and will require an advanced HAZUS analysis or other type of analysis at the campus level and CSU system-wide. The CSU system’s leadership may consider developing such data sets in the future.

Erosion

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another”. 57 Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While

coastal erosion can happen in any storm, it is more likely during El Nino events, which occur every 5-7 years.

Other incidents of erosion, such as occurs around buildings, is relatively non-spatial and can occur in any locations with conducive soil structure and a source of movement, such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. For the purpose of a CSU system-wide analysis, the erosion hazard poses a consistent risk across those areas of each campus with erosion-prone characteristics.

Extent of the Hazard

Erosion is occurring along the entire Pacific coastline. The USGS estimates that the state’s shorelines with the highest rates of erosion are in Monterey Bay and San Francisco South, and that, in general, erosion hazards have increased.\(^{58}\) While there is no published scale of severity or extent for this geologic hazard on any individual campus, erosion is likely to occur over the long term if conditions remain favorable. That said, given the historical occurrence of erosion and the presence of erosion-prone characteristics on some campuses and not on others, it is prudent that the planning committee ranks the overall extent of this hazard as **Moderate**.

History of the Hazard

CSU Sacramento, CSU Sonoma, and CSU Chico, while not reporting any past significant incidents of erosion on their campuses, have established mitigation projects in nearby riverways to reduce erosion and sediment loads. Similarly, several coastal campuses – CSU Monterey Bay, CSU Long Beach, and CSU San Francisco - have not reported erosion on campus, but are proximal to shoreline mitigation projects.

CSU campuses in Channel Islands, Dominguez Hills, Fresno, Fullerton, and Humboldt have all experienced past incidents of erosion. These incidents ranged from minor incidents around clogged drainage pipes or construction sites to more severe incidents causing structural damage (CSU Fullerton).

Potential Impacts of the Hazard

Coastal erosion can result in severe impacts to local infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change

---

raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. Therefore, given some history of occurrence and the Moderate extent of erosion, the probability of future occurrence across all CSU campuses is **Likely**. However, conditions could emerge in the future which may further increase the probability, precipitated by climate change, changes in land-use or other factors. It is anticipated that CSU leadership will monitor such changes and respond accordingly with viable and cost-effective mitigation efforts.

**Vulnerability to the Hazard**

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU System infrastructure, buildings, and agriculture located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. As such, CSU leadership may consider performing a system-wide analysis to identify such at-risk buildings, infrastructure, slopes and soil types on each campus in the future.

In the communities surround CSU campuses, erosion vulnerabilities include agricultural sector jobs, riverine ecosystems and coastlines, and water quality.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on CSU campuses. CSU leadership may choose to pursue such estimates in the future, should modeling improvements be made.

**Vulnerability Assessment Conclusions**

While the ability to predict future erosion on CSU campuses is limited, the core indicator for monitoring and identifying erosion vulnerability on each campus is the condition of its soil relative to the topography of, building locations, overall campus layout and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Extreme Heat**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.59

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.60 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feels” hotter. The combination of temperature and humidity is known as the heat index.61

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.62 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.63

**Location of the Hazard**

Extreme heat events are non-spatial, and can occur throughout a given campus footprint, and across several CSU campuses at one time, particularly during the summer months.

**Extent of the Hazard**

The CSU campuses experience a wide variance of maximum average temperatures in June through October. Northern campuses and those closer to the ocean see more moderate temperatures, on average, while urban campuses and those closer to the desert are likely to experience higher temperatures and less sea breeze. For example, the monthly average maximum temperatures in Fresno during the summer months of June through September range from 91 – 99° F. In contrast, Rohnert Park, home to Sonoma

---

60 National Weather Service. *Discussion on Humidity.* Retrieved 01.22.21 from: [https://www.weather.gov/lmk/humidity](https://www.weather.gov/lmk/humidity)

61 Ibid.

State, typically sees summer high temperatures ranging from 79 – 82°F. Given that 26 heat events spanning 40 days has taken place on CSU campuses from 2006-2021 (15 years), along with the historical and potential impact of the hazard, the system-wide planning committee ranks the extent of the hazard overall as **Moderate**.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104°F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105°F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

The following figure depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

Figure 3-10: Methodology for Determining Heat Index.

As the heat index rises, so does the potential danger to people and animals. The following table shows the health hazards associated with extreme heat.

---

Table 3-19: Health Risks Associated with Heat Index

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, excessive heat is a hazard of concern for CSU. In just the last few years, the following extreme heat events have occurred at CSU campuses:

In addition to these specific excessive heat events, the NCDC database lists hundreds of additional incidents when the temperature has hit 100° F or greater.

**Potential Impacts of the Hazard**

During an excessive heat event, CSU campuses may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

**Probability of Future Occurrence of the Hazard**

Across all CSU campuses, extreme heat events have occurred annually in for the past several years. Given that 26 events have occurred over the past 15 years (1.7 events per year), it is **Highly Likely** that the hazard will occur annually.
Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat and are more likely to suffer illness or death as a result.66 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

The majority of CSU campuses with a serious risk of excessive heat events have precautions in place in case of power outages (e.g., back-up generators) as well as mitigation plans for heat waves, such as cooling centers and safety plans for extremely hot days. While this is a hazard that the university will continue to experience with increasing regularity, most campuses have enough knowledge and familiarity with the hazard to handle the risks and vulnerabilities.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at CSU campuses is limited, the effects of climate change may provide some information. Figure 3-11 (below) from the Environmental Protection Agency (EPA) depicts the change in temperature over the last century. Areas of Southern California have warmed as much as 3 – 3.5 degrees. Coupled with less rainfall, this may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.67 Although CSU leadership maintains sound notification and protective measures for campus populations, it will monitor climate conditions and changes in order to mitigate any increased frequency, intensity and duration of extreme heat events in the future.

---

Extreme Cold

Description of the Hazard

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.68

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.69 This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underly tissue. It causes a loss of feeling and color in the

affected areas of the body, and most often affects the nose, chin, fingers, or toes.\textsuperscript{70} It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases.\textsuperscript{71} The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6° F. Hypothermia occurs when your body temperature falls below 95° F.\textsuperscript{72} As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

**Location of the Hazard**

Extreme cold events are a non-spatial hazard and could occur throughout a given campus and at various CSU campuses simultaneously.

**Extent of the Hazard**

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in Monterey Bay are typically in the mid-40s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in Monterey Bay was 20° F on December 22, 1990.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30° F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.\textsuperscript{73}

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure xx (following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow). Although CSU maintains sound cold weather notifications and protective measures for campus populations, given that the historic low temperature across CSU-based communities averages about 15 degrees, during a future

re-occurrence, if accompanied by even a 20mph wind, the wind chill could dip below zero
degrees. As such, the planning committee ranks the overall extent of the hazard as
**Moderate.**

Figure 3-12: Methodology for **Determining Wind Chill**

---

In 2011, the National Weather Service introduced an experimental program that
issued warnings for extreme cold events, independent of other severe weather warnings.
The test areas included North and South Dakota and Minnesota. However, in 2012, after a
single season of use, the program was abandoned, based on reports of confusion among
test audiences.\(^7^4\)

**History of the Hazard**

Based on data gathered from the National Centers for Environmental Information (NCEI)
Storm Events Database, a few of the CSU campuses have experienced frost/freeze events,
when the temperature has reached below freezing temperatures. However, actual
extreme cold events are rarely, if ever experienced. [Records for extreme cold were first
kept starting in 1996.]

Potential Impacts of the Hazard

An extreme cold or frost/freeze event, depending on the campus’s level of preparation for cold weather, could lead to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

Probability of Future Occurrence of the Hazard

As most CSU campuses are located in temperate climates, it is **Unlikely** that this hazard will occur annually.

Vulnerability to the Hazard

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more likely to suffer illness or death as a result.\(^75\) This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

Overall, CSU campuses do not consider extreme cold to be a significant hazard. A few campuses have warning systems in place for frost/freeze events, reminding students and staff to keep building temperatures at a certain level to prevent pipes from freezing and bursting. As this is not a hazard that the university will experience regularly, most campuses have enough knowledge and familiarity with the hazard to handle the risks and vulnerabilities.

---

Estimate of Potential Losses

Based on the previous historical occurrences of extreme cold events, annualized losses are considered to be negligible. In an extreme cold event, loss of human life or health impacts are a greater concern than is property damage.

However, it is worth considering that a frost/freeze or extreme cold event could cause substantial losses to the university’s major agricultural programs if the event were prolonged and occurred during the growing season. Campuses with agricultural production programs include:

- Cal Poly San Luis Obispo
- Humboldt State
- Fresno State
- CSU Chico
- Cal Poly Pomona

However, based on the previous historical occurrences of extreme cold events, annualized losses are considered unlikely.

Vulnerability Assessment Conclusions

Although CSU leadership maintains sound notification and protective measures for campus populations, CSU will monitor climate conditions and changes in order to mitigate any increased frequency, intensity and duration of extreme cold events in the future.

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.
**Hazardous Materials**

**Description of the Hazard**

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”76 Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health.77 Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs)**: During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:
- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel, chemicals, hazardous waste sites and/or gas pipelines are located to varying degrees on each campus. Refer to each campus Annex for maps identifying the location of hazardous materials on each campus. At larger scales (beyond the campus planning area) hazardous materials are located throughout cities and counties and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard. That said, in essence, the extent of the risk is primarily driven by human error and/or equipment/containment failure which itself is driven by inadequate maintenance in some cases. For the CSU planning committee, while some historical events have been severe in some CSU-based communities, the vast majority of events on and off campus are minor and localized. As such, it is prudent to rank the extent of the hazard for the CSU 23 campus system as **Moderate** and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

---

Moreover, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including over 150 problems from the Loma Prieta Earthquake alone. 81 Finally, it should be noted that the plan indicates that it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located. 82

According to the 2018 CA State Hazard Mitigation Plan, with regard to natural-technological hazard events (Natechs), 400 hazardous materials events are tied to 32 past earthquakes, including over 150 Natech events from the Loma Prieta Earthquake alone.

For more details on specific hazmat events, please refer to the local, county and/or multi-jurisdictional hazard mitigation plans where CSU campuses are located at: https://www.caloes.ca.gov/cal-oes-divisions/hazard-mitigation/hazard-mitigation-planning/local-hazard-mitigation-program

With regard to hazmat incidents at CSU campuses, Chico State, CSU - Bakersfield, CSU - East Bay, Humboldt State, CSU - Long Beach, CSU - Los Angeles, CSU - Monterey Bay (gas leak), San Francisco State, and San Jose State have experienced minor, isolated chemical spills mostly in science labs. In 5 of these 9 cases, building evacuation was required. For example, following the 1994 Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result

in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

With regard to the natural environment, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health. Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs. 83

Potential Impacts of the Hazard

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. Any educational institution with a science lab might be at risk for a chemical spill leading to adverse health outcomes.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

83 2018 California State Hazard Mitigation Plan, section 9.2.
Probability of Future Occurrence

The probability of occurrence for a hazmat release on campus can be viewed in two different ways: first, is that the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, 9 of 23 campuses have experienced at least 1 hazmat event from approximately 2015 – present. At a minimum, this equates to at least 1 hazmat event at 40% of CSU campuses over the past 6 years or a 6.5% chance of occurrence per year for each campus across the 23-campus system. Of course, changes in risk and vulnerability factors such as materials oversight and handling practices or changes in the amount of chemicals or exposure may affect future probability.

Assessment of Vulnerability

Hazardous materials pose ubiquitous risk to the state and to the communities encompass each of CSU’s 23 campuses. Although campus planning committees identified different types, degrees, and combinations of campus-level hazmat risks, and that students, staff, critical facilities, water and natural resources in close proximity to hazardous substances are most vulnerable, it is quite difficult to produce a quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control.

Therefore, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local level, and the related difficulty in predicting future events and their primary and secondary impacts, it is prudent to assume for planning purposes that each vulnerability is a sub-set of the larger community’s vulnerability, and that all CSU campuses and their communities are vulnerable as a whole or single system. As such, CSU leadership maintains an equal degree of vigilance to mitigate the vulnerability of each campus because its leadership approaches vulnerability at the system-wide level. And, the starting point for the CSU planning committee’s assessment of vulnerability is that students, staff, critical facilities, water and natural resources in close proximity to hazardous substances are most vulnerable.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the
probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

**Vulnerability Assessment Conclusions**

It is well understood that with regards to hazmat vulnerability, each CSU-based community and county operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of local mitigation plans and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU system as a whole and of the individual campus, while campus-level risks and vulnerabilities vary, in many cases they are not discreet or isolated, but are exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw final conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

**Identified Data Limitations**

Campus planning committees have provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
Landslide

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within the deposition zone and can result in downstream flooding. Post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have

occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation as identified in Figure 3-13 below.

With regard to landslide locations at CSU campuses, ten (10) are not located within or near a landslide susceptibility zone, two (2) campuses are located somewhat near Moderate susceptibility zones, one (1) is located somewhat near a High susceptibility zone, six (6) are adjacent or connected to Moderate susceptibility zones, and four (4) are adjacent or connected to High landslide susceptibility zones. Please refer to the landslide susceptibility map within each campus Annex for details.

Figure 3-13: Deep-Seated Landslide Susceptibility in California

---

Extent of the Hazard

CSU System campuses are susceptible to seismic activity, wildfires, and intense rainfall

---

that can lead to landslides. The ten campuses identified as connected to Moderate and High Landslide Susceptibility Zones are most at risk of direct impacts. That said, the history of landslides impacting a CSU campus is limited to one event at Cal Poly San Luis Obispo. However, landslide events have occurred near other campuses and within the broader communities. At a minimum, the indirect impacts of landslides may cover a larger geographical extent than that of indirect impacts. As such, the planning committee ranks the overall extent of the hazard as **Moderate**.

**History of the Hazard**

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, landslides are a hazard of concern for the CSU System. Since 1971, the following severe landslides have occurred proximal to CSU campuses. In addition, in 2017, a dormitory on the Cal Poly SLO campus was evacuated and closed as a result of encroaching landslide debris on a hillside east of the dormitory. The Hall remains closed.

Potential Impacts of the Hazard

Landslides can result in physical damage to buildings and property and have the potential to significantly affect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are often triggered by other natural hazards, such as earthquakes and heavy rainfall, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events and fires, landslides will likely occur more often. The USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California. Although the location of the majority of campuses is outside the landslide risk zones, the planning committee ranks the probability of the landslide hazard for the campuses as a whole as Possible. In addition, the probability of a given campus experiencing secondary effects of a landslide occurring beyond the campus footprint resulting in on-campus loss of power or transportation disruption is Possible.

Vulnerability to the Hazard

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. As identified in the Location section, vulnerable CSU assets and populations include
the six campuses connected to moderate landslide zones (Channel Islands, East Bay, Monterey Bay, San Diego, San Francisco, San Marcos) and most vulnerable are the four campuses located within high risk landslide zones (Humboldt, Pomona, San Bernardino, San Luis Obispo).

**Estimate of Potential Losses**

Due to data, cost and time limitations, the current planning effort does not include models for estimating potential losses from a landslide directly impacting the campus. That said, if relevant data and modeling becomes available, the planning committee may consider their use in the future.

Although the economic impact of landslide damage can exceed that of the direct repair costs, the current planning effort does not include methods for estimating indirect costs related to CSU System campuses. That said, given that the vast majority of campuses lies outside of landslide susceptibility zones, it may be the case that potential economic losses will be weighted toward secondary losses that may potentially far outweigh the costs of any direct impacts possible at only a small minority of campuses.

**Vulnerability Assessment Conclusions**

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact CSU System campuses in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employees’ ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**

The ability to predict the location of future landslides is limited. However, if relevant data and modeling becomes available, the planning committee may consider their use in the future.

However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.

**Power Outage**

**Description of the Hazard**

In the event of a power outage, most aspects of modern life will be disrupted. Almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of a commodity like power can affect the campus in various ways like forcing campus closures to limiting campus
operations. These interruptions can be cascading effects from other hazards, such as the result of major windstorms, winter storms and wildfire, which can prompt an intentional disruption or Public Safety Power Shut Off (PSPS).

A power outage event can interrupt day-to-day operations of CSU campuses, like in-person classes, impede, or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center and close restaurants around campus and outside the campus. Additionally, thousands of CSU student residents in on-campus housing would also be affected by a power outage on campus.

Additionally, a severe outage in the surrounding cities, counties or neighboring communities would also directly affect campuses and their communities.

An electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of **intentional** disruptions:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Other classifications of power outages include the following:
- Repair Outages: An outage caused by unexpected circumstances, such as traffic accidents or severe weather. Energy utility agencies work to repair these outages quickly to restore power to the affected areas.
- Maintenance Outage: A scheduled outage that occurs when we turn the power off for equipment upgrades. Energy utility agencies notify business and resident customers in advance if they will be affected by a maintenance outage.
- Rotating Outage “Rolling Blackouts: A strategic and controlled power outage enact as a last resort when there is a statewide Stage 3 Emergency declared. Sometimes called a “rolling blackout.”
- Public Safety Power Shutoff (PSPS) Events energy utility companies proactively turn off power to help reduce the risk of wildfires. These events will primarily be called during extreme and potentially dangerous weather conditions. Turning off power is a critical decision, and a number of factors are considered before that decision is made. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Additional notifications will be made throughout the outage when power has been shut off and when it has been restored. Some situations prevent agencies from providing advance notice due to weather conditions and other circumstances beyond the agency’s span of control.

**Location of the Hazard**

The power outage hazard poses an equal risk to all areas of a given CSU campus and to all areas within the CSU campus system. At the local level, if a CSU-based city or county is experiencing a power outage, it is likely that the particular campus is also experiencing a power outage.

Regarding the location of electrical utility infrastructure, the image below highlights the expansive system of electrical power utility companies spanning throughout the State of California. Some providers are large utility corporations, while others are small municipal agencies sourcing their energy from the larger corporations creating a tremendous demand from few resources, intensifying the need during extreme temperature periods of the year.
Historically, the most consistent reason causing power outages are falling trees. In Southern California Santa Ana Winds can cause destruction due to its extremely strong winds. Windstorms with 45 mph+ winds can cause flying debris and downed utility lines. Even minor windstorm can create damage when tree limbs break off and bring down power lines, potentially causing fatal accidents through electrocution along with blackouts. In addition, extremely wet weather conditions can saturate soils weakening the
tree foundations and enabling trees to fall during high wind winter storms in northern and high-altitude parts of the state.

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO), which is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities. CAISO is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of “stage alerts” to the media based on system conditions. The alerts are as follows:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other causes of power outages in California, CSU campuses maintain safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Based on these factors, and the fact that recorded outages have taken place on CSU campuses, the campus-wide planning committee ranks the overall extent of the power outage hazard as Moderate.

History of the Hazard

The State of California has experienced power outages over time and every summer the state consistently experiences a high demand for electrical energy. The state’s electric utility providers, like the Los Angeles Department of Water and Power (LADWP), Power Gas & Electric (PG&E) and southern California Edison (SCE), to name a few, have taken mitigation efforts to reduce outages and blackouts whenever possible. In the last few years, California has exercised planned outages by implementing PSPS strategies to reduce the affects and hazards related to extreme weather event disasters, like wildfires. Also, major crimes (fraud) have led to power crises resulting in major power outages affecting residents and commerce.

- 2019 California power shutoffs, a series of PSPS, or "Public Safety Power Shutoff" events, that occurred in several California counties in October 2019 to prevent the risk of catastrophic wildfires caused by power lines.
- California electricity crisis, blackouts affecting California in 2000 and 2001, due to an energy shortage caused by market manipulation.
- 1996 Western North America blackouts, two blackouts affecting California and other areas in 1996.
- 2011 Southwest blackout, a blackout affecting Arizona, Southern California, and Mexico in 2011

**Note:** Based on interview data as part of the current planning effort, approximately half of all CSU’s 23 campuses have experienced at least one power outage. For more information, please refer to the History of the Hazard section in each campus annex.

### Potential Impacts of the Hazard

The California State University System infrastructure relies on electricity for basic business and educational operations. During a widespread power failure, it may take anywhere from several hours to days to restore operations if a significant event occurs. Electrical power may be the only cooling source for many individuals on the campuses and their communities, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

Although CSU campuses have specific power outage protocols it can impact the operations of the universities depending on the severity of the outage. During daytime hours, the University may remain open and business and instructional operations will remain on-going to the maximum extent possible. It will be expected that the areas surrounding the campus, including streetlights, will also experience a blackout.

For example, crises created by droughts, delays in approval of new power plants, and market manipulation decrease power supplies to California’s constituency. An extreme or unexpected increase cause an incredibly high increase in wholesale prices during hotter months. In addition, rolling blackouts adversely affect many businesses dependent upon a reliable supply of electricity, and inconvenienced many retail consumers. Additionally, residents affected by blackouts and brownouts may face health hazards and economic losses due to power failure.

Finally, flood events present potential issues involving power outages if any facilities inundated with floodwaters create disruptions at nearby electrical grids. Disruptions involving floodwater can create significant and lengthy power outages with challenging issues preventing immediate remedies for repair. Additionally, power outages create caveats in emergency personnel reaching crisis events due to possible traffic build up due to streetlights and traffic lights also malfunctioning.

### Potential Impact and the Effect of Climate Change

Climate change is expected to bring more frequent and intense natural disasters. Over the years, what was once a disaster uncharacteristic to landscape is now occurring outside of historical areas. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016.
Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

Along with storm and wind related falling trees, other factors contribute to both intentional and unintentional outages, such as wildfire and extreme heat, and climate change further exacerbates these power outage factors throughout California, including the CSU System. It is important to decipher the frequency and intensity of extreme temperatures throughout the year in California, especially in the widespread areas covered by the state’s largest provider coverage areas, Power, Gas & Electric and Southern California Edison. The probability of California experiencing an extreme temperature can be difficult to quantify but is considered a hazard that occurs yearly during the same seasonal periods throughout the calendar year. Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. The length of days above 100 degrees may also increase severely and has already done so in the last 20 years, especially in southern-most and northern-most regions of California. Additionally, future years are projected to see a continuation or worsening of fire events across California increasing the need for Public Safety Power Shut-Offs (intentional power outages). More than half of the CSU System campuses fall within a Public Safety Power Shut Off (PSPS) affected location. Based on the above factors, the planning committee ranks the probability of future occurrence as **Likely**.

**Vulnerability to the Hazard**

When an energy shortage creates power disruptions it can have a major effect on the entire state or different regions individually or in synchronicity. Different regions on opposite ends of the state may be enduring separate heatwaves creating a high demand for power causing an unintended power outage or a combination of extreme heat and
wind events prompt the need for intended power outages or Public Safety Power Shut-off (PSPS) events.

Based on the data available, and in consideration of the increasing effects of climate change, the probability of future occurrences prompting intentional outages or creating unintentional power outages, the CSU system’s overall vulnerability to the hazard is high. Nonetheless, it would serve the campus well to be able to mitigate and cope with an interruption to electrical power.

As such, in an effort to expand resilience, the state of California’s energy infrastructure has been designed to cope with the state’s highly variable conditions and frequent disruptions from wildfires, storms, and floods. As a result, power outages caused by these events are short-term and limited to regional impacts, which, in turn, reduces the vulnerability of the California State University System. Moreover, CSU leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

Estimate of Potential Losses

California’s energy infrastructure is designed to cope with the state’s highly variable conditions and frequent disruptions from wildfires, storms, and floods. Generally, power outages caused by these events are short-term and limited to regional impacts. Of more concern are system-wide outages or shortages caused by a major disruption in supply or transmission. No data on power outage related dollar losses to CSU campuses is currently available. The system-wide planning committee may pursue such data in the future.

For information related to each campus’s loss assessment, each campus hazard profile indicates that although the economic impact of power outage damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to the CSU system.

Vulnerability Assessment Conclusions

The primary concern for CSU System leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at any campus. In response, safety and operations protocols center on the following “direct impact” set of concerns:

Elevators, entry ways, air filtration systems and lighting provide campus communities with the necessary infrastructure and systems to function and navigate through each campus and to maintain a safe campus environment and visibility during nighttime hours. The vulnerable population (especially students with physical disabilities) may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors, and locks and lights may impede on a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to
“by-hand” procedures and paper copies may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

In order to reduce such vulnerabilities, CSU leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

**Identified Data Limitations**

Although it is recognized that PSPS events impact campuses across the state, mitigation efforts are necessary to manage the power outage hazard on a yearly basis, regardless of whether hard data on campus level dollar losses is available.

Potential economic impacts (regardless of whether or not data or modeling on such losses is available), are most closely tied to continuity of campus operations, and campus operating costs are already built into campus budgets. Therefore, the ability to quantify potential losses is, practically speaking, secondary to the cost expenditures which will necessarily be approved by CSU leadership for campus operations recovery in the event of an outage. Nevertheless, CSU leadership will continue expanding the use of energy efficiency standards for equipment and infrastructure to help reduce or eliminate power outage response and recovery costs. For example, California utilities energy efficiency programs since the 1970s offer some of the lowest-cost energy resource options to help meet California’s and the CSU System’s energy and climate policy objectives consistently across all CSU campuses and sites.
**Tsunami**

Description of the Hazard

A tsunami is a wave triggered by any form of land displacement along the edge or bottom of an ocean or lake. Land displacement can be in the form of submarine landslides or submarine dip-slip faults. These types of faults cause ruptures that result in seafloor uplift or down-drop. This mass movement translates to a tsunami or gravity wave within the overlying water at the surface.

Tsunamis travel radially outward from the area of initiation. The size of a tsunami is proportional to the mass that moved to generate the tsunami. As a tsunami approaches the shore and the depth of the water column decreases, the energy in the wave pushes the wave crest above the water surface resulting in a larger wave height. Wave runup is the elevation above mean sea level on dry land that a tsunami reaches. Run-up is what causes inundation of coastal areas that are below the run-up height.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing severe damage to coastal development. At the shoreline, tsunamis may take the form of a fast-rising tide, a cresting wave, or a bore (a large, turbulent wall-like wave). The bore phenomenon resembles a step-like change in the water level that advances rapidly (from 10 to 60 miles per hour). The first wave is usually followed by several larger and more destructive waves.

Location of the Hazard:

According to the 2018 CA State Hazard Mitigation Plan, tsunami locations span 94 incorporated communities and 83 unincorporated areas across 20 coastal counties.

For CSU campus locations, the CSU – Chancellor’s Office campus (below) is located within a mapped tsunami zone, and based on current mapping, it appears that the Humboldt State campus is located within, or very close to within the inundation zone. As such, the tsunami hazard will be fully profiled for these 2 campuses.

- Humboldt State University (City of Arcata, Humboldt County)
- CSU - Chancellor’s Office (City of Long Beach, Los Angeles County)
Figure 3-15: Tsunami Inundation Area Near Chancellor’s Office
In order to highlight the relationship between universities and the broader community, although just two campuses (above) are located in a tsunami inundation zone, the campuses (below), although not located in a mapped tsunami zone, are located in a municipality and/or county with some coastal areas at risk of tsunami impacts. In two cases, university resources are utilized for emergency response and/or post-disaster recovery:

According to the Ventura County Emergency Operations Plan, CSU – Channel Islands is identified as an evacuation point for displaced people due to its high-ground location; and, according to the CSU – Monterey Bay planning team, the campus maintains an Emergency Operations Center and displaced persons evacuation point also due to its high-ground location.

Note: The tsunami hazard will not be profiled for the campuses listed (below), as the tsunami inundation maps in each campus’ annex indicates that the main campus location is outside of the tsunami inundation zone. Where noted, some schools maintain assets or
satellite facilities within the inundation zone. The extent, probability and potential impact of a tsunami discussed below are applicable to those satellite/coastal facilities or assets.

- CSU – Channel Islands (Ventura County) **
- CSU – East Bay (Alameda County)****
- CSU – Dominguez Hills (Los Angeles County)
- CSU – Fullerton (Los Angeles County)
- CSU – Long Beach \textit{(Long Beach State; Los Angeles County)} ***
- CSU – Los Angeles (Los Angeles County)
- CSU – Maritime Academy (Solano County) *
- CSU – Monterey Bay (Monterey County) **
- CSU – Northridge (Los Angeles County)
- CSU – Pomona \textit{(Cal Poly Pomona; Los Angeles County)}
- CSU – San Jose \textit{(San Jose State; Santa Clara County)} *
- CSU – San Marcos (San Diego County)
- CSU – San Diego \textit{(San Diego State; San Diego County)}
- CSU – San Francisco \textit{(San Francisco State; San Francisco County)} *
- CSU – San Luis Obispo \textit{(Cal Poly SLO; San Luis Obispo County)}

* Main campus is not in a mapped tsunami zone but has assets on waterfront inundation zone such as docks, boats and buildings.

** Not in a mapped tsunami zone; campuses maintain EOC related functions for tsunami.

*** CSU – Long Beach campus is not located in a tsunami inundation zone, and the tsunami hazard does not pose a risk to campus buildings or infrastructure as identified. However, according to the campus planning committee, the university leases a building that it believes lies in the tsunami inundation zone. Although not mapped, the university may verify and map the property’s location in the future, only with the permission of the property owner.

**** Main campus is not in zone but has assets in downtown Oakland – inundation zone borders part of downtown; need to identify downtown asset location relative to the inundation zone.

All remaining CSU campuses identified (below) are neither located in a tsunami zone nor located within a municipality or county at risk to tsunami.

- CSU Bakersfield
- CSU – Chico (Butte County)
- CSU – Fresno (Fresno County)
- CSU – Sacramento (Sacramento County)
- CSU – San Bernardino (San Bernardino County)
- CSU – Sonoma (Sonoma County)
- CSU – Stanislaus (Stanislaus County)
Extent of the Hazard:

The factors shaping the extent or severity of the hazard are a combination of geophysical forces (the amount of vertical and horizontal motion of the sea floor, the area over which it occurs, and the efficiency with which energy is transferred from the earth’s crust to the ocean water) and the geographic range of coastal development to be impacted.

More specifically, as a tsunami approaches the shore, wave run-up is the elevation above mean sea level on dry land that a tsunami reaches. A tsunami’s potential severity can be forecasted as a function of the wave’s mass along with the difference between the wave’s run-up height and the ground elevation of the affected coastal location.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height. 87

With regard to the aforementioned CSU main campuses or off-campus assets located within the tsunami inundation area, given no history of tsunami impacts,

History of the Hazard:

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. That said, no tsunamis have impacted CSU campus locations.

According to the National Centers for Environmental Information (NCEI), have been eight tsunamis have caused damage to ports and harbors or coastal inundation in California since 1946. The most significant events are as follows:

- In 1964, a tsunami caused by a Magnitude 9.2 earthquake offshore from Alaska resulted in 13 deaths in California and destroyed portions of downtown Crescent City.
- A 2006 tsunami (originating in the Kuril Islands region north of Japan) caused approximately $20 million in damage to Crescent City harbor.
- A 2010 tsunami (originating offshore from Chile) caused millions of dollars in damage to ports and harbors in the state.
- A tsunami in 2011 (caused by a Magnitude 9.0 earthquake offshore of Japan) killed one person at the mouth of the Klamath River and caused up to $100 million of damage to 27 ports, harbors, and marinas throughout the State. 169

87 NOAA. About Tsunami. Retrieved 03.31.2021 from:
http://www.prh.noaa.gov/itic/library/about_tsu/faqs.html#1
damage occurred in Crescent City, Santa Cruz and Moss Landing harbors and a federal disaster was declared in Del Norte, Santa Cruz, and Monterey Counties. Both Crescent City and Santa Cruz harbors sustained damage to all docks, and oil spills and water/sediment contamination that resulted from sunk or damaged boats. Because recovery efforts in these two harbors took several years to complete, both harbors incurred business/economic losses that have been difficult to recapture.

Summary of Tsunamis Along the California Coast Since 1946

- March 11, 2011, Offshore Japan Earthquake 9.0, $100 million (1 death)
- February 27, 2010 Offshore Chile Earthquake 8.8 $3 million (No deaths)
- November 15, 2006 Kuril Islands Region Earthquake 8.3 $20 million (No deaths)
- March 28, 1964 Offshore Alaska Earthquake 9.2 $20 million (13 deaths)
- May 22, 1960 Chile Earthquake 9.5 $1 million (2 deaths)
- March 9, 1957 Aleutian Islands Earthquake 8.6 <$1 million (No deaths)
- November 4, 1952 Kamchatka Earthquake 9.0 <$1 million (No deaths)
- April 1, 1946 Aleutian Islands Earthquake 8.8 <$1 million (2 deaths)

Additionally, the Worldwide Tsunami Database provides information on tsunami run-up levels and earthquake magnitude factors. Although data for the most recent events is not available, additional (earlier) tsunami events are recorded.

Potential Impact of the Hazard:

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing total devastation to coastal development. Potential impacts to at risk CSU campuses or other assets include destruction of campus buildings and infrastructure, destruction of the natural environment, destruction of boats and coastal development, and loss of life in the area surrounding the campuses. Tsunamis that impact both harbors and communities also can produce free-floating debris hazards and environmental contamination from chemical spills.

89 Global Historical Tsunami Database, National Center for Environmental Information, 2019
The configuration of the coastline, the shape of the ocean floor, and the characteristics of advancing waves play important roles in the destructiveness of the waves. Bays, sounds, inlets, rivers, streams, offshore canyons, islands, and flood control channels may cause various effects that alter the level of damage. Offshore canyons can focus tsunami wave energy, and islands can filter the energy. It has been estimated that a tsunami wave entering a flood control channel could reach a mile or more inland, especially if it enters at high tide. The orientation of the coastline determines whether the waves strike head-on or are refracted from other parts of the coastline.

**Probability of Future Occurrence of the Hazard:**

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. If we consider historical occurrence as one data set for estimating future events, the average rate of occurrence over the past 150 years is 1 tsunami every 1.9 years.

The rate of future occurrence may change, and the California State Tsunami Program is trying to refine the accuracy of the data. In doing so, the State Tsunami Program is completing a set of Probabilistic Tsunami Hazard Analysis (PTHA) maps representing risk levels from 100-year to 3000-year average return periods. Analysis using these probabilistically based products will allow for a more common platform for comparison to other seismic and flood probabilistic analyses.90

**Vulnerability to the Hazard:**

For the purpose of this section, the discussion will center on the two Main campuses located in the inundation zone: Chancellor’s Office and Humboldt State University. It should be pointed out, however, that the discussion of main campus vulnerability (below) also applies to the satellite/coastal assets owned by San Francisco State, San Jose State and Maritime Academy. Long Beach State and CSU-East Bay may also have vulnerable coastal assets (to be determined). See the Location of the Hazard section (above) for more information.

Population and asset vulnerabilities are a function of “maximum run-up” projections modeled by the University of Southern California and distributed by the California Office of Emergency Services. The tsunami model was the result of a combination of inundation modeling and onsite surveys and determined the maximum projected inundation levels from tsunamis along the entire coast of Los Angeles County.

The most notably vulnerable campus is the Chancellor’s Office located in an inundation zone with a maximum run-up of approximately 42 feet. This means that based on the worst-case scenario tsunami, the displaced water level would be approximately 42 feet above the normal tide for that day and time. As such, given that the Chancellor’s Office is

90 2018 State of California Hazard Mitigation Plan

3-110
located on the oceanfront, it is clearly vulnerable to catastrophic loss, as are any staff or
visitors unable to evacuate with proper lead-time.91

With regard to Humboldt State University’s vulnerabilities, the campus planning
committee indicates that the California Geologic Survey datasets will be utilized in the
near future to analyze critical assets on campus that fall within zones of vulnerability. That
said, the planning committee indicates that the Aquatic Center and the Coral Sea
(research and classroom vessel) are located in the tsunami zone along with campus
access and egress routes. A tsunami could create isolated islands of people due to the
inundation, and no evacuation or access to hospital services. In fact, according to the
2018 State Hazard Mitigation Plan, Humboldt county’s population is among the most
vulnerable to tsunami related injury and life safety issues due to its close proximity to the
Cascadia Subduction Zone.92

Population Vulnerabilities
The populations most vulnerable to the tsunami hazard are the elderly, disabled and very
young who reside near beaches, low-lying coastal areas, tidal flats and river deltas that
empty into ocean going waters. In the event of a local tsunami generated near the coast,
little warning time would exist, so more of the population would be vulnerable, and to
some extent, this vulnerability pertains to the Humboldt State University planning area
and the Chancellor’s Office location in Long Beach. Though no data is currently available
for Long Beach, it is densely populated which creates a high degree of vulnerability. For
Humboldt County, HAZUS analysis of the inundation area indicates that a tsunami event
could displace 1,441 people, with up to 96 people needing short-term shelter assistance.

Property Vulnerabilities
The impact of tsunami waves and the scouring associated with debris that may be carried
in the water could be damaging to all structures along beaches, low-lying coastal areas,
tidal flats and river deltas. The most vulnerable structures are those in the front line of
tsunami impact and those that are structurally unsound. According to the 2018 State of
California Hazard Mitigation Plan, Long Beach exhibits among the state’s highest number
of businesses located in the tsunami zone.

Critical Facilities and Infrastructure
The following infrastructure is vulnerable to damage in Long Beach, CA and Humboldt
County, CA:

- Water Proximate Infrastructure—Breakwaters and piers collapse, sometimes
  because of scouring actions that sweep away their foundation material and
  sometimes because of the sheer impact of the tsunami waves.

91 2016 City of Long Beach Hazard Mitigation Plan.
92 2019 Humboldt County Operational Area Hazard Mitigation Plan
- Flood Control Systems—Floodwaters can back up drainage systems, causing localized flooding. Culverts can be blocked by debris from tsunami events, also causing localized urban flooding.
- Utility Systems—Floodwaters can get into drinking water supplies, causing contamination. Sewer systems can be backed up, causing waste to spill into homes, neighborhoods, rivers and streams. Tsunami waves can knock down power lines and radio/cellular communication towers. Power generation facilities can be severely impacted by wave action and by inundation from floodwater.
- Fuels— Destruction of fueling infrastructure and related environmental and potable water contamination can occur. In Humboldt County, the Chevron terminal is located in the tsunami inundation zone on Humboldt Bay and receives most of the vehicle fuel for the county by barge.

Estimate of Potential Losses

Estimates of potential losses specific to CSU campuses have not been conducted yet. In addition, no estimated loss data is currently available for the City of Long Beach, although the local mitigation plan indicates concern for losses related to fires from damaged ships in ports or from ruptured coastal oil storage tanks and refinery facilities in the port area. That said, according to the State plan, technological Improvements have been made in the ability to estimate losses from tsunami impacts which can be brought to bear on loss estimation for CSU campuses in the future.

For Humboldt County, the HAZUS analysis indicated that 49 percent of the county’s exposed structures (997 structures) would be impacted by the modeled scenario event with a damage estimate of $448M dollars (buildings, contents). The estimated damage value is associated with the tsunami wave only; it does not include additional damage as a result of debris battering structures or losses to from boats, bridges or utility lines. Moreover, HAZUS estimates of damage to critical facilities and infrastructure in the county show an estimated 141 facilities impacted with 66 facilities showing a light to moderate degree of damage (10% - 49% structural damage).

Vulnerability Assessment Conclusions

According to the 2018 State of California Hazard Mitigation Plan, community exposure to tsunamis in California varies considerably—some communities may experience great losses that reflect only a small part of their community and others may experience relatively small losses that devastate them. Among the 94 incorporated communities and 83 unincorporated areas of the 20 coastal counties, the communities of Alameda, Oakland, Long Beach, Los Angeles, Huntington Beach, and San Diego have the highest number of people and businesses in the tsunami inundation zone, and the communities that are most vulnerable to injury and life safety issues exist within Del Norte and Humboldt counties due their close proximity to the Cascadia Subduction Zone. As discussed, the Chancellor’s Office (Long Beach), Humboldt State University, San Francisco State, San Jose State, Maritime Academy (and potentially Long Beach State and CSU-East Bay) overlap with these highly vulnerable areas.
For improving assessments of vulnerability, FEMA has developed a new tsunami loss estimation module for HAZUS using existing numerical model results for tsunami inundation, flow depth, velocity, and force. This HAZUS module allows new capability for estimation of economic losses, and site-specific analysis of content losses, casualties, infrastructure damage, and evacuation time. The module calibrates losses based on safe zones and community preparedness levels.

Along with new probability-based tsunami maps, the HAZUS module will improve the ability to compare tsunami impacts to those of other hazards. Moreover, the probability mapping will be used for numerous applications including identifying potential tsunami hazard “zones of required investigation” under the Seismic Hazards Mapping Act and will assist state and local agencies in making land use planning decisions. They will also help regional and state planners understand the flood potential from tsunamis representing different risk levels.93

**Note:** To download the Community Exposure to Tsunami Hazards in California report visit the USGS website: [http://pubs.usgs.gov/sir/2012/5222/](http://pubs.usgs.gov/sir/2012/5222/).

**Identified Data Limitations:**

As identified in the Vulnerability Summary (above), with regard to the current planning effort, the primary data limitations for assessing the tsunami hazard for CSU campuses (Chancellor’s Office and Humboldt State University) are asset valuations lying within the tsunami inundation zone, and the need to apply FEMA’s new probability mapping techniques and tsunami loss estimation module to the footprint of each campus. That said, CSU leadership and planning teams intends to pursue such data in the future.

---

**Volcano (Associated Air Quality)**

**Description of the Hazard**

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”94

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in

---

93 2018 State of California Hazard Mitigation Plan
water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

**Location of the Hazard**

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. Chico State and Fresno State are located in counties partially within the Lassen Volcanic Center and Long Valley Volcanic Region hazard zones, but the campuses themselves are not. No CSU campuses are located in a volcano hazard zone.

**Extent of the Hazard**

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. While no CSU campuses fall within these estimated zones, lighter dustings of ash outside of those areas may directly or indirectly impact a CSU campus.

**History of the Hazard**

Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

**Potential Impacts of the Hazard**

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As no CSU campus is proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major

---

96 https://www.usgs.gov/observatories/california-volcano-observatory/california-has-active-and-hazardous-volcanoes#:~:text=At%20least%20seven%20California%20volcanoes,they%20will%20erupt%20again%20in%202021
electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations on a CSU campus.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. The USGS has estimated the probability of future eruption of five of the seven active volcanoes in California:

- Coso Volcanic Field: .5 percent chance in the next 30 years
- Lassen Volcanic Center: .5 - 2 percent chance in the next 30 years
- Long Valley Volcanic Region: 2.5 percent chance in the next 10 years
- Medicine Lake Volcano: 1 percent chance in the next 30 years
- Mount Shasta: 3.5 percent chance in the next 30 years

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU campuses, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions
CSU campuses are unlikely to experience the direct impacts of a volcanic event. While any campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting CSU campuses is very low.

**Identified Data Limitations**

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This fact, together with the infrequent occurrence of volcanic explosions and the variety and complexity of factors determining type and extent of impacts, make the quantification of potential loss difficult.

**Wildfire**

**Description of the Hazard**

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. In general, a wildfire is defined as any free-burning vegetative fire that initiates from an unplanned ignition, whether natural (e.g., lightning) or human-caused (e.g., powerlines, mechanical equipment, escaped prescribed fires), where the management objective is full suppression. While wildfires can potentially lead to benefits to an ecosystem if within the range of natural variability for a given ecotype and geographical area, they can also lead to deleterious effects to both the natural and built environment.

In California, the combination of complex terrain, Mediterranean climate that annually facilitates several monthlong rain-free periods, productive natural plant communities that provide ample fuels, and ample natural and anthropogenic ignition sources, has created a land forged in fire. A century of fire exclusion has led to a significant buildup of fuels in many mixed-conifer forests, which historically experienced frequent, low-intensity surface fires.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire
behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

Fire science distinguishes between two types of wildfires: “wildland” fires, which burn predominately in undeveloped areas, and “wildland-urban Interface” (WUI) fires. This distinction is important because mitigation, damage, and actions related to the two types may differ significantly.

Wildland fires that burn in natural settings with little or no development are part of a natural ecological cycle and may be beneficial to the landscape if they burn within the historic range of variability for fire size and intensity. Many species are adapted to California’s natural fire regimes and flourish after a low or mixed severity burn. These fires also enhance ecosystem function by creating landscapes that have more variation, are more resilient to other disturbances, and are better able to withstand extremes in precipitation. The wildland fire may result in secondary negative impacts in the form of air pollution, soil erosion (resulting in siltation of streams and lakes), or mudslides, though these impacts tend to be far less than would occur following high severity fires in areas of historic fire suppression. However, unless these fires or their related secondary impacts occur in or near developed areas (see Map 8.C), they are rarely classified as disasters because they do not affect people or the built environment. Wildland fires, regardless of size, that burn primarily on federally managed lands are only rarely classified as disasters.

The WUI is characterized by the intersection of the natural and the built environments and has been defined as “the area or zone where structures and other human development meet or intermingle with undeveloped wildland or vegetative fuels” (Society of American Foresters). The WUI can be configured in many ways including a classic “interface” (e.g., a community that abuts a National Forest at a distinct boundary), an “intermix” (e.g., vegetative fuels distributed between buildings throughout a subdivision between buildings), or an “occlusion” (e.g., a community that completely surrounds a designated open space area).

**Location of the Hazard**

The potential for destructive wildfires exists throughout the state. Historic fire perimeters indicate a pattern that many wildfires occur in the foothills of both coastal and interior
mountain ranges, especially in mountainous regions near populated areas of Southern California. Some areas in California are prone to burn with higher regularity than other areas and therefore have a heightened exposure to loss. This is of special concern in the South and Central Coast bioregions, which show the highest frequencies. These bioregions have significant amounts of shrubland plant communities where wildfires typically occur as high- intensity, stand-replacement fires.

While higher fire frequency has historically occurred in mixed-conifer forests, those fires were commonly low- intensity surface fires. However, given fuel buildup following a century of fire exclusion, a lengthened fire season predicted by many climate-change models, forest management practices which removed many of the older, larger trees, and massive tree die-off following epidemic bark beetle infestations, fires in mixed-conifer forests are likely to continue to grow in both size and intensity. 97

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. Many WUI fires occur in areas that have a historical pattern of wildland fires that burn under extreme conditions. The most common extreme fire behavior factor is high, dry, warm foëhn winds, such as Santa Ana or Diablo winds, that occur in a predictable location and seasonal pattern. The pattern of increased damages is directly related to increased urban spread into areas that have historically had wildfire as part of the natural ecosystem.

While most counties have experienced a state or federally declared fire disaster, the majority of those declarations have occurred in Southern California, due to a large population base located in areas that commonly have volatile shrublands, steep slopes, and annually occurring Santa Ana winds. However, there are growing concerns regarding increased wildfire frequency and severity in Northern California shown in climate change models. Recent catastrophic fire events throughout Northern California, in counties including Butte, Sonoma, Napa, Solano, Shasta, Mendocino, Lake, Glenn, and Colusa Counties, substantiated this concern.

With respect to CSU campuses, according to current mapping, eight (8) out of 23 campuses (roughly one-third) are located in or extremely close to a Fire Hazard Severity Zone (FHSZ). Of those, 4 campuses (Channel Islands, Pomona, San Bernardino and San Marcos campuses) are located in a Very High hazard zone, while CSU – Sacramento is located in a High severity zone, and CSU – Monterey, CSU – Northridge, and San Diego State are located in a Moderate severity zone.

**Extent of the Hazard**

Among California’s three primary hazards, wildfire, and particularly wildland-urban interface (WUI) fire, has represented the third greatest source of hazard to California, both in terms of recent state history as well as the probability of future destruction of greater
magnitudes than previously recorded. With the more recently catastrophic wildfire events starting in 2017, fire has emerged as an annual threat roughly comparable to floods. (Fire and flood fire hazards are surpassed only by high magnitude earthquake hazards.)

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the National Fire Danger Rating System (NFDRS), from the US Forest Service’s Wildland Fire Assessment System.

Table 3-24: National Fire Danger Rating System

Wildfire is a hazard with a somewhat unpredictable nature. While it is at least somewhat possible to determine the areas that may be subject to experiencing wildfire, it is not possible to determine in advance how or where a wildfire will begin. Only the conditions for a wildfire can be predicted with any accuracy.

Some areas in California are prone to burn with higher regularity than other areas and therefore have a heightened exposure to loss. This is of special concern in the South and Central Coast bioregions, which show the highest frequencies. These bioregions have significant amounts of shrubland plant communities where wildfires typically occur as high-intensity, stand-replacement fires. While higher fire frequency has historically occurred in mixed-conifer forests, those fires were commonly low-intensity surface fires. However, given fuel buildup following a century of fire exclusion, a lengthened fire season predicted by many climate change models, forest management practices which removed many of the older, larger trees, and massive tree die-off following epidemic bark beetle infestations, fires in mixed-conifer forests are likely to continue to grow in both size and intensity.
Given the identified locations of 8 campuses in FHSZ’s along with the increased prevalence and severity of the wildfire hazard state-wide, (including students, staff and faculty having lost homes to wildfire), the CSU system-wide planning committee ranks the overall extent of the hazard across all CSU campuses as **Moderate**.

**History of the Hazard**

The State of California has a long history of chronic and destructive wildfires throughout the state. 8,300 wildfires have burned 928,245 acres across the state over the 20-year period between 2000 and 2020. While California has long been recognized as one of the most fire-prone natural landscapes in the world, WUI fires represent an increasingly significant concern for the State of California. While the number of acres burned
fluctuates from year to year, a trend over the last 30 years that has remained constant is the rise in wildfire-related losses. In 2018, most local governments that had submitted Local Hazard Mitigation Plans (LHMPs) identified fire and WUI fires as specific hazards. 2020 was the worst wildfire season in California history, consuming more than 4.2 million acres. California has a chronic and destructive WUI fire history with significant losses of life, structures, infrastructure, agriculture, and businesses.

Driven by worsening drought conditions and above-normal temperatures, California has passed new legislation investing millions of dollars towards hiring additional fire personnel, buying mechanical equipment, building defensible spaces and developing vegetation-management projects that will control and slow down the fires. In 2020, state wildfires consumed more that 4.2 million acres. In April 2021, state officials approved the allocation of more than $80 million in emergency funds to elevate forest management and wildfire response efforts. The funding will specifically promote 1,399 additional firefighters within CAL FIRE and will allow training of fire crews ahead of peak fire season, which occurs between July through October.99

Wildfire has not occurred directly on the footprint of CSU campuses, although CSU – San Marcos did have a wildfire reach the edge of campus in 2014 which required evacuation and campus closure for a week. Also, students, faculty and staff are frequently affected by smoke and poor air quality produced by wildfires. Some members of these populations have also lost homes to wildfire.

Potential Impacts of the Hazard

Wildfire poses significant risk to the people of California and their homes. According to California’s Forests and Rangelands 2017 Assessment, development patterns around the state have resulted in construction of approximately 3 million housing units within Fire Hazard Severity Zones (FHSZ) that are potentially at risk from wildfire. Of those housing units, close to 2.2 million are within the Wildland Urban Interface (WUI), 83 percent of which are in “dense interface” and 17 percent of which are in “intermix”.

Even relatively small-acreage WUI fires may result in disastrous damage. Most WUI fires are suppressed before they exceed 10 acres. The remainder usually occur during episodes of hot, windy conditions that exceed initial attack capabilities and, therefore, are more likely to cause heightened losses to the built environment. Dense interface WUI can be described as a fully developed residential area that terminates at the edge of a wildland area, while intermix WUI, as the name indicates, occurs where residential units are intermittently scattered through a wildland area. Fires that originate in the WUI from structures or other improvements can cause damage to wildland resources. The challenge is in how to reduce wildfire losses within a framework of California’s diversity of natural and built environments.

While some of the standing timber value can be salvaged following a wildfire, many of California’s timber assets are exposed to significant risk from wildland fire. initial

changes in the post-fire environment may cause temporary habitat loss and species dislocation. In the short term, the presence of partially burnt vegetation reduces recreational and open space values. Fires can also destroy campgrounds, trails, bridges, and other recreational facilities within the area. Wildfires can have significant adverse effects on watershed lands, watercourses, and water quality. Fire and the subsequent removal of vegetative cover increase the potential rate of soil erosion and new sediment sources. Potentially affect water quality through increased sedimentation and increased turbidity and through increases in nutrient loadings.

Probability of Future Occurrence of the Hazard

In California, 8,300 wildfires have burned 928,245 acres over the 20-year period between 2000 and 2020. This translates to an average of 415 fires annually with an average of 112 acres burned per wildfire event. Given a fairly consistent distribution of High and Very High severity zones from the north to the south of the state, it is reasonable to rank the annual probability of a wildfire occurrence within a CSU-based community as Possible. Also, because roughly one third of CSU campuses are located in Fire Hazard Severity Zones, and that such zones exist within all the broader communities and counties where CSU campuses are located, it is prudent to rank the annual probability of a wildfire occurrence on a CSU campus also as Possible.

In general, large, destructive wildfires are increasingly becoming the “new normal” in California, even with increased firefighting personnel, equipment, technology, and training. While wildfires are a natural part of California’s landscape, the fire season in California and across the West is starting earlier and ending later each year. The length of fire season is estimated to have increased by 75 days across the Sierras and seems to correspond with an increase in the extent of forest fires across the state.100 Climate change is considered a key driver shaping greater wildfire probability of occurrence, extent and severity. These increases are expected to be greatest in the mixed-conifer forests of the Sierra Nevada and Northern California; less impact is expected for fires in chaparral shrublands, which are expected to be more driven by increases in human-caused ignitions. In general, future years are projected to see a continuation or worsening of fire events across California related to the following:

- Increased fuel loading following a century of fire exclusion policies
- More human-caused ignitions
- Climate change, which is influencing drought
- Greater silvicultural insect and disease impacts
- Increased tree mortality
- Lengthening of the “fire season,” or annual time frame during which vegetative fuels are receptive to combustion.

While ignition sources for urban conflagrations within developed areas have been reduced via improvements in community design, construction materials, and building fire

---

100 https://www.fire.ca.gov/incidents/2021/
protection systems, continued development in fire-prone areas subsequently increases the potential for an urban conflagration via WUI fires, especially in high-density developments that are adjacent to wildland areas that are prone to seasonably strong, dry winds (e.g., Diablo winds in the Bay Area or Santa Ana winds in Southern California).

Vulnerability to the Hazard

While structures burn every year, most damaging fires have occurred when ignitions coincided with severe weather that included critically high temperatures, low relative humidity, and perhaps most importantly, high winds. Once thought of as a seasonal hazard, wildfires are an almost everyday occurrence in California. California has widespread WUI fire vulnerability due to an increasing pattern of projected development encroaching into previously wildland area resulting in increased WUI zones.

Of those, 4 campuses (Channel Islands, Pomona, San Bernardino and San Marcos campuses) are located in a Very High hazard zone, while CSU – Sacramento is located in a High severity zone, and CSU – Monterey, CSU – Northridge, and San Diego State are located in a Moderate severity zone. CSU campuses not located in a fire hazard severity zone are not directly vulnerable to fire damage, but are still vulnerable to the effects of wildfire smoke and its air quality impacts to campus populations and operations.

Figure 3-18: California’s Projection of Development
California has widespread WUI fire vulnerability, as indicated on the map, based on CAL FIRE FRAP data. The map depicts an increasing pattern of projected development encroaching into previously wildland area resulting in increased WUI zones.

According to California’s Forests and Rangelands 2017 Assessment, development patterns around the state have resulted in construction of approximately 3 million housing units within Fire Hazard Severity Zones (FHSZ) that are potentially at risk from wildfire. Of those housing units, close to 2.2 million are within the Wildland Urban Interface (WUI), 83 percent of which are in “dense interface” and 17 percent of which are in “intermix”. Dense interface WUI can be described as a fully developed residential area
that terminates at the edge of a wildland area, while intermix WUI, as the name indicates, occurs where residential units are intermittently scattered through a wildland area.

The degree of vulnerability for CSU campuses is greater or less depending on their location within (Low to Very High) wildfire hazard severity zones, along with the natural fuels and incendiary materials on campus in closest proximity to such severity zones. Of those, 4 campuses (Channel Islands, Pomona, San Bernardino and San Marcos campuses) are located in a Very High hazard zone, while CSU – Sacramento is located in a High severity zone, and CSU – Monterey, CSU – Northridge, and San Diego State are located in a Moderate severity zone. CSU campuses not located in a fire hazard severity zone are not directly vulnerable to fire damage but are still vulnerable to the effects of wildfire smoke and its air quality impacts to campus populations and operations. In response, the SOP’s and other wildfire monitoring and fuel maintenance protocols are in place on each campus. Protocols include air quality warnings and evacuation procedures reduce the vulnerability of campus populations, assets and operations.

Estimate of Potential Losses

Currently, a dollar loss estimate of direct and indirect impacts from wildfire has not been calculated for CSU campuses as whole or individually. CSU leadership may pursue such data in the future.

Vulnerability Assessment Conclusions

Wildfires are the most frequent source of declared disasters and account for the third highest combined losses. Most Local Hazard Mitigation Plan reviewed in 2017 in Southern California and San Francisco Bay Area counties, some Central Valley counties, and many North Coast and Sierra Mountain counties rated wildfires high in their hazard rankings. For CSU campuses, the degree of vulnerability is greater or less depending on their location within (Low to Very High) wildfire hazard severity zones, along with the natural fuels and incendiary materials on campus in closest proximity to such severity zones.

Identified Data Limitations

As indicated above, data on direct and indirect losses form wildfire are not currently available. In addition, a comprehensive assessment and tracking of wildfire-prone campus assets and incendiary potential of natural fuels within and around CSU campuses has not been conducted. CSU leadership may pursue such data in the future.

Severe Weather (Wind, Tornado, Hail, Lightning)

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves,
unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

---

105 Retrieved on 07.17.2021 from [https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions](https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions)
The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses.

**Regional Climate Influences on Severe Weather across California**

Most of the weather in California is influenced by the wet-winter/dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events that CSU campuses systemwide experience, other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.

**Types of Storms in California**

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage. The SHMP also lists the following types of storms that produce hazardous conditions and potential damage

---

106 Retrieved on 07.16.2021 from https://www.pmel.noaa.gov/elnino/what-is-el-nino
throughout the state of California.111 These storms affect (in varying degrees) all CSU campuses.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.112 Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.113 Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.114 *Severe thunderstorms* are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.115 116

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.117

- **Wind storm**: marked by high wind with little or no precipitation.118

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.119

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.120

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air

---

115 Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
116 Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.121

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.122

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.123 Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” 124

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system.

---

High Winds, Strong Winds, and Thunderstorm Winds

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.125

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.126

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.127

Please note: Straight-line wind is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.128 However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

Tornadoes

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.129 This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.130

On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{131}

**Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.**

*Santa Ana Winds*. A type of wind hazard that is peculiar to Southern California is called a *Santa Ana Wind*. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{132} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{133} (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

\textsuperscript{131} Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions

\textsuperscript{133} Retrieved on 07.13.2021 from https://www.weather.gov/safety/wind-mountain-valley
**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.  

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining

---

narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.136 137 138

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.139 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.140

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.141

---

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{142} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, and at all main campuses, satellite campuses, research facilities, conference centers, and other CSU-owned facilities and properties. For each CSU campus – and for each campus’ surrounding community – no one area is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain-valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all CSU system campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is county-level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to each CSU campus reflect those of the campus’ surrounding community and County. As a result, all assets and people at all CSU campuses are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards.

In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard for the CSU system as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking for the CSU system.

**Wind Hazard: Non-Rotational**

The Beaufort Scale (Table 3-XX) is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.\textsuperscript{143} First developed in 1805, it is still used today to estimate wind strengths.\textsuperscript{144}

\textsuperscript{143} Retrieved on 07.15.2021 from https://www.rmets.org/resource/beaufort-scale

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE** for the CSU system.
Extent: Tornado

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\textsuperscript{146}

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 3-26: Fujita Tornado Scale (Pre-February 2007) \textsuperscript{147}

</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the hail hazard as **LOW** for the CSU system.
**Extent: Lightning**

The National Weather Service (NWS) uses a Lightning Activity Level (LAL) scale to indicate the frequency and character of cloud-to-ground (C/G) lightning. The scale uses a range of 1 – 6, with 6 being the high end of the scale. Table below provides details of the LAL scale.

Table 29: Lightning Activity Level (LAL) Scale\(^{150}\)

</tbody>
</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW** for the CSU system.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms.\textsuperscript{151} \textsuperscript{152} That said, according to the \textit{Glossary of Meteorology} published by the American Meteorological Society (AMS), a thunderstorm is reported as \textit{light, medium, or heavy} according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\textsuperscript{153}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- \textbf{Airmass Thunderstorm}: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{154}
- \textbf{Frontal Thunderstorm}: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{155} or
- \textbf{Squall-line Thunderstorm}: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\textsuperscript{156} \textsuperscript{157}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as \textbf{LOW} for the CSU system.

**History of the Hazard**

Severe weather hazards have been an annual occurrence in across the CSU system. Historical data for these hazards are presented below.

\textsuperscript{151} Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
\textsuperscript{152} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
Historical Storm Data Collection: NCEI Storm Events Database Searches for Wind, Tornado, Hail, and Lightning Hazard Events

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\footnote{ Retrieved on 07.19.2021 from \url{https://www.ncdc.noaa.gov/stormevents/details.jsp}} For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\footnote{ Dos Santos, Renato. (2016). Some Comments on the Reliability of NOAA’s Storm Events Database. \textit{SSRN Electronic Journal}. DOI: \url{10.2139/ssrn.2799273}. Retrieved 07.19.2021 from \url{https://papers.ssrn.com/sol3/papers.cfm?abstract_id=2799273}} To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected from January 1, 1996 through April 30, 2021. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

Average Number of Annual Hazard Event Occurrences

Information obtained from the NCEI Storm Event Database shows the number of events (or occurrences) of hazard events in California Counties from January 1, 1996 through April 30, 2021. Average historical frequencies of occurrence are then calculated by dividing the number of events for each hazard by the number of years of records analyzed (i.e., 25½ years). (Please note that wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.) More detailed campus-level results, including historical severe weather hazard losses, can be found in the CSU Campus Annex sections of this document.

Historical Data Collection for Wind Hazards Not Included in NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April.\footnote{ Retrieved on 07.14.2021 from \url{https://agupubs.onlinelibrary.wiley.com/doi/epdf/10.1002/2016GL067887}} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textbf{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting
up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{161} \textsuperscript{162}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red and are defined as those events that are above the 90th percentile of all events on record.

Figure 3-20: Mean Annual Frequency of Santa Ana Wind events (1948-2012)\textsuperscript{163} \textsuperscript{164}

**Diablo Winds**

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^{165}\)

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\(^ {166}\)

Figure 3-21: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\(^{167}\)

---

**Sundowner Winds**

Strong sundowner wind events occur approximately **2-3 times per year**. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per

---

\(^{166}\) Retrieved on 07.15.2021 from [https://www.fireweather.org/diablo-winds](https://www.fireweather.org/diablo-winds)

\(^{167}\) Retrieved on 07.13.2021 from [https://www.fireweather.org/diablo-winds](https://www.fireweather.org/diablo-winds)
century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.¹⁶⁸

**Historical Severe Weather Event Data Collection Results: NCEI and non-NCEI Sources**

Table below shows the average annual frequencies of wind, tornado, hail, and lightning hazard events in counties in which CSU campuses are located. Information regarding the presence of regional mountain-valley wind hazards is also included in Table 3-XX.

Table 2-30: Average Annual Frequency of Severe Weather Hazard Events for all CSU Campuses (01/01/1996 to 04/30/2021)¹⁶⁹

<td>$311,500</td>
<td>$95,695,150</td>
<td>$315,230</td>
<td>$183,581,380</td>
</tr>
</tbody>
</table>

It is important to note that for all counties in which CSU campuses are located, 87% of all deaths, 73% of all injuries, 90% of all estimated property damages, and 48% of all estimated crop damages have been attributed to wind hazard events alone. Hail hazards are responsible for more than half (52%) of all crop damages.

**Potential Impacts of the Hazard**

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths and injuries, and property, crop, and economic damage. All assets and people within all CSU campus areas systemwide are at risk from the effects of severe weather hazards.

---

Wind Hazards (Including Tornadoes)

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at each CSU campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and mission for each CSU school.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

Hail

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

Lightning

Lightning strikes the United States about 20-25 million times a year.\textsuperscript{171} Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.\textsuperscript{172} Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.\textsuperscript{173} (Commercial claim payouts for lightning losses for the U.S. were not available.)

Hazard Mitigation Plans Used to Determine Severe Weather Hazard Potential Impacts

Severe weather hazard potential impacts for all CSU campuses have been determined by examining the most recent local hazard mitigation plans for communities in which the campuses are located. These local hazard mitigation plans are listed in Table 3-XX.

### Potential Impacts of Severe Weather Hazards at CSU Campuses

The potential impacts of severe weather hazards for all CSU campuses are presented below in Table below. Potential impacts ratings for each hazard sub-type are the following (in order of level of potential impact): Minimal (MIN), Minimal to Moderate (MIN/MOD), Moderate (MOD), Moderate to High (MOD/HI) and High (HI).

Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year. Future occurrences of such events are projected to increase in both their frequency and intensity. Table 3-XX shows the overall severe weather hazard probabilities of future occurrence for all CSU schools. (Category descriptions of probability of future occurrence are presented at the beginning of this document.) Wind hazard events are (by far) the most frequent of the four (4) severe weather hazards profiled here.

Vulnerability to the Hazard

All people, structures, and assets on all campuses are vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. Each CSU school also has vehicles that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects all CSU campuses. Each of the hazards associated with severe weather can result in losses throughout the planning area.
The population across the entire CSU system varies throughout the day. As of Fall, 2019, CSU systemwide had a total of 480,541 students and 53,763 faculty and staff.\textsuperscript{174} All are at risk from severe weather events, with 534,304 being directly vulnerable in this scenario.\textsuperscript{175} (Please note: These population numbers do not include visitors to or contracted employees working on CSU campuses.) No loss of life from severe storms has been recorded on a CSU campus.

### Property

All structures at all CSU campuses are at risk from severe weather. There are approximately 2,448 buildings across the CSU system that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. According to the most current information provided by CSU campus, total replacement costs due to severe weather hazard for all CSU campuses are at least $8,351,298,709 for 1,661 buildings and are unknown for the remaining 787 buildings. Building replacement costs for each CSU school are presented in Table 3-XX below.

(Please note: An analysis of projected dollar losses of campus buildings from severe weather as a percentage of building replacement costs is not currently available. CSU leadership may pursue such data in the future.)

**Vulnerability Assessment Conclusions**

Severe weather presents a variety of hazards to all CSU campuses. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to the entire CSU system.

It is evident that the California State University system has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committees for each CSU school will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.
Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
3.4 Climate Change

Introduction

Globally, the climate is experiencing climbing average temperatures, with the past five years being collectively the warmest years in the modern record. 2016, 2015, 2017 and 2018 were the four warmest years recorded.\textsuperscript{176} NASA predicts that the global temperatures will continue to rise for decades. The Intergovernmental Panel on Climate Change (IPCC) forecasts a temperature rise of 2.5 to 10 degrees Fahrenheit over the next century.\textsuperscript{177} Climate change related hazards have intersectionality with multiple hazards and extensive impacts. For example, public health, agriculture, economic and ecosystem hazards arise from:

- Extreme heat and cold events
- Drought and impacted water quality
- Fire, smoke and PSPS shutdowns
- Storms and long-term aftermath
- Agricultural products and food impacts

California’s experience of dramatic impacts of climate change on communities continue to grow and are projected to become more severe and damaging. Hazard mitigation and adaptation are complementary strategies for reducing the likelihood of unmanageable change, managing the risks, and taking advantage of new opportunities created by our changing climate. Climate change impacts are primary and secondary, with both rapid and slow onset.

Potential climate impacts must inform and influence emergency management decisions for all communities, including the CSU campuses. Addressing climate change in this HVRA is intended to provide information that reflects data, recent trends, perceptions, and invite consideration for both near term and future projections in hazard mitigation planning for the CSU system. How to address these climate impacts and projections in hazard risk reduction for campus emergency management requires further data analysis and collaborative planning discussions. Even within that context, projections related to climate change are not firmly fixed. In the section entitled, Anticipating Climate Changes, from Second Nature, the authors caution campuses planners to remember that future projections are uncertain.

“High resolution future climate projections are not always supported by the science. Specific future values imply accuracy in prediction, which the scientific community does not currently have. Campus vulnerability assessments will need to incorporate some degree of uncertainty in projections. Framing the process as building overall resilience

\textsuperscript{177} NASA. The Effects of Climate Change. \url{https://climate.nasa.gov/effects/}. Accessed December 15, 2019.
capacity (instead of responding to a specific expected climate change) can help reduce vulnerability to a range of possible impacts.”

Ultimately, the purpose of an assessment is to inform the planners of the good ways to further build risk resilience in the physical campus, its systems and amongst the populations served. Second Nature defines climate resilience: Resilience is the ability of a system or community to survive disruption and to anticipate, adapt, and flourish in the face of change. This section introduces the concerns of climate change being experienced throughout the state of California, impacts on vulnerable populations, and offers insight into how the campus emergency managers are experiencing climate impacts in relation to their campuses, risk resilience efforts, capacities, and resources.

Climate Terms

In the context of climate change related risk reduction, many definitions are available, and extensive resources are available building off the Intergovernmental Panel on Climate Change (IPCC) Climate Change 2014 work178 and offer examples of the impacts of climate change in helping frame climate risk.

Hazard: refers to any potential occurrence of a natural or human-induced physical event that may cause damage to property, infrastructure, livelihoods, service provision, environmental resources etc. As an example, as sea level rises, increased frequency of inundation of an area during storm event is a potential hazard for a low-lying coastal area.

Risk: the potential for consequences where something of value is at stake and where the outcome is uncertain, recognizing the diversity of values. Risk is often represented as probability of occurrence of hazardous events (likelihood) or trends multiplied by the impacts (or consequences) if these events or trends occur. Risk results from the interaction of vulnerability, exposure, and hazard (IPCC 2014). As an example, as sea level rises, increased frequency (likelihood) of inundation (a hazard) of an area during storm event can put the structural integrity of a nearby infrastructure, such as road into a risk.

Vulnerability: The propensity or predisposition to be adversely affected. Vulnerability encompasses a variety of concepts and elements including sensitivity or susceptibility to harm and lack of capacity to cope and adapt (IPCC 2014). As an example, older populations are more sensitive to heat-stress and have limited physical capacity to adapt, therefore highly vulnerable during a heatwave.

Exposure: refers to the degree to which a system is exposed to a given hazard (E.g., sea-level rise). As an example, a coastal community in a low-lying area can be exposed to certain degree of hazard of inundation during a storm event.

Sensitivity: refers to the degree to which a system is affected by, or responsive to a hazard. In other words, sensitivity captures the potential of a system to be impacted by a

178 https://www.ipcc.ch/site/assets/uploads/2018/02/WGIIAR5-PartA_FINAL.pdf
hazard. Sometimes sensitivity is determined by the criticality of the service that the system provides. For example, a community uses a road located close to the low-lying area of the coast as its main access to a major hospital.

Adaptive Capacity: describes a system’s ability to adjust to climate change (including climate variability and extremes) to moderate potential damages, to take advantage of opportunities, or to cope with the consequences (IPCC2014).

**Impacts of Climate Change**

Climate change results in numerous specific effects to human lives, health, environment and the economy. An overview of these impacts include\(^1\):*

- **Agricultural threat.** Rising heat, combined with wildfire, drought, and agricultural pests, will negatively have impacts on overall yields of major U.S. crops. Livestock will also be negatively affected by elevated heat. Internationally, prices and availability of certain foods will be affected. While the rise in temperature may prove beneficial for some crops in some areas, such as in the Northern Great Plains, California will more likely see negative impacts. \(^2\)

- **Air pollution.** Air pollution includes ground-level ozone and particulate matter. Ozone is due to heat, chemicals and methane. Particulates are produced mainly from wildfires but from other factors, as well. Health problems include diminished lung functions, asthma and even death.

- **Allergens.** Pollen-related allergies increase with warmer temperatures and increased carbon dioxide. Increased rainfall and rising temperatures contribute to indoor air pollutants.

- **Civil unrest.** Food shortages, public health outbreaks, long-duration water shortages or contaminations, and other climate induced incidents may cause stress on populations and result in increase in civil unrest.

- **Drought threat.** The rising air and water temperatures, along with change in precipitation, intensify droughts. The prediction of future warming will add to the stress on water supplies in the western United States.

- **Extreme Heat.** Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

- **Food security and agriculture.** Due to climate change, some aspects of food production (plants, livestock and fish production) and quality are at risk, threatening food availability, prices and distribution. Rising prices cause food insecurity, which often cause people to eat calorie-rich, but nutrient poor foods,

---

which in turns leads to obesity. Higher CO2 levels are associated with reduced protein in many crops. Further, as temperatures increase, farmers are expected to use more pesticides to manage pests and weeds.

- **Illness.** Changing temperatures also brings illnesses related to frequency and severity of allergic illnesses (e.g., asthma and hay fever).

- **Precipitation.** While an increase in extreme precipitation and total precipitation have been shown to contribute to flood related injuries and deaths, many other hazards exist once the flood has abated. Waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

- **Vector born disease.** The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

- **Wildfire.** Increased temperatures and droughts contribute to wildfire conditions. Wildfires produce smoke, carbon monoxide, nitrogen oxides, and organic chemicals leading to ozone release. Asthma, chest pain, COPD, and other respiratory ailments may follow. Already, wildfire is associated with hundreds of thousands of deaths annually worldwide.

### Climate Impacts on Socially Vulnerable Populations

Socially vulnerable populations often have lesser capacity to improve their resilience than that of communities with greater access to resources and social capital. As has been experienced in the COVID pandemic, poverty and social exclusion are tied to health inequalities, and climate change exacerbates health disparities. Pre-existing social, health and economic factors often intersect and combine to contribute to communities’ increased degrees of vulnerability and resilience. For example, low-income households are further exposed to heat-related health risks because the houses are not being insulated sufficiently and lack air conditioning. These are significant concerns with the increasing numbers of heat incidents in the state.

Public health surveillance in Sacramento County has shown that the climate-related issues (extensive heat, poor air quality, ground water impacts) lead to more Emergency Department (ED) visits, more requests for inhalers, and greater stress on the more vulnerable people (e.g., those without homes) and those who have no insurance. Furthermore, the California Department of Public Health reports the increased public health risks and risk indicators include heat-related emergency department visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.
Impact on socially vulnerable populations can be exemplified in California’s wildfires. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte County in 2018, 62 of them were at least 65 years old.

Safeguarding those populations who are most vulnerable, and the importance of the vulnerability of students in any community, particularly the CSU campuses, is recognized. The increase and severity of California’s climate events may affect CSU’s most vulnerable populations in their ability to cope with, respond to and adapt to the increased. The influence of climate challenges on CSU’s populations who are impacted by their adaptive capacities in their level of exposure to campus and community hazards, vulnerabilities (physical and social), and social capital in their community. (These issues are the focus of the social vulnerability section of this HVRA.) As many of the CSU student population reflect communities of color, first generation college attendees, and as commuters, are transportation dependent, the increasingly serious climate change impacts may add an extra dimension of potential marginalization and hardship. The issue of equity becomes even more problematic if their ability to become (and remain) resilient and absorb stressors is reduced because of increased limitations to access of resources, despite those resources offered by the CSU system.

Hazards and Climate Change in California

Climate change is expected to bring more frequent and intense natural disasters to California. Over the years, what was once a disaster uncharacteristic to landscape is now occurring outside of historical areas. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The following are specific concerns related to the changing hazards landscape in California.

**Extreme Heat**

---

The climate induced extreme heat impact leads to public health threats, including illness, disease, smoke, loss of clean water. It leads to agricultural threats, with stress on both agricultural crops and animals. An importantly for the state of California, extreme heat leads to an exacerbated drought threat and increased wildfire threat as the local flora dry out.

**Wildfire**

The warming change to the climate is driven in part due to carbon dioxide and greenhouse gases caused by human activity. The wildfire threat especially occurs in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Fire is related to dryer conditions, typically also associated with drought. Impacts of increased heat include increased wildfire threat and public health threats. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Fire cause smoke issues and is related to elevated AQI.

While frequent fires are an integral part of the California natural history, the size and ferocity of fires has grown since the 1980s, with 15 of the largest 20 fires on record having occurred since 2000. Climate change plays a role in magnifying these fires, as California has warmed approximately three degrees Fahrenheit (more than the global average of one degree Fahrenheit) over the last century. This hotter air draws more moisture out of plants, trees, shrubs and grasslands, leaving areas more susceptible to burning. Challengingly, with every degree of warming, the impact to dry conditions is exponential. The most critical time is the end of fall, when conditions are driest, but before the winter rains have come. To exacerbate the effect, the rain is warmer, meaning snow lines are higher, snow levels are lower, and snow is melting earlier, which in turn extends the dry season. CalFire notes that the fire season is now 75 days longer within the past few decades. California’s east-to-west winds that traditionally come over the Sierras further exacerbate the fire risk, as gusts can reach 70-80 miles an hour, which spread a wildfire even wider. The 2018 Camp Fire in Butte County and the 2017 Thomas Fire in Ventura and Santa Barbara County were fanned by such gusts.

**Public Safety Power Shutdowns (PSPS) Situation/ Energy Shortage**

PSPS has been implemented across the state of California with the intention of reducing wildfire risk during periods of high winds and significant fire threat. The PSPS has impacts on the state’s high-risk wildfire areas. Loss of power creates economic hardship to the region, as many businesses close, including gas stations, grocery stores, and local retail establishments. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply

---

of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands. Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

Climate change is a contributor to power outage hazards in California, including the CSU System. It is important to decipher the frequency and intensity of extreme temperatures throughout the year in California, especially in the widespread areas covered by the state’s largest provider coverage areas, Power, Gas& Electric and Southern California Edison. The probability of California experiencing an extreme temperature can be difficult to quantify but is considered a hazard that occurs yearly during the same seasonal periods throughout the calendar year.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. The length of days above 100 degree may also increase at a rate that is difficult to keep pace, as we have experienced in the last 20 years, especially in southern-most and northern-most regions of California. Additionally, extreme heat and wind events as a result of climate change; future years are projected to see a continuation or worsening of fire events across California increasing the need for Public Safety Power Shut-Offs (intentional power outages), although, the CSU Chancellor’s Office does not consider its campus susceptible to Public Safety Power Shut Offs, more than half of the CSU System campuses fall within PSPS affected locations.

**Floods, Storms and Water Quality**

Drawing the specific comparison of flood relationships to climate change is difficult. However, the *Fourth National Climate Assessment* contained a Climate Science Special Report that demonstrated climate change “has detectably influenced” several of the water-related variables that contribute to floods, such as causing heavier rainfall and
snowmelt. The conclusion is floods are exacerbated by climate change. The frequency and strength of winter storms has increased across the nation which are being exacerbated by climate change. Other severe storm trends, including thunderstorms, tornadoes and hail, are still being studied as to their relationship to climate change. 185

Storms, floods, and water runoff, (as well as extreme heat events), all that can be influenced, increased and exacerbated by climate change impact water quality, impacting human health, animal health, ecosystem health. Contaminated water also negatively impacts industries that rely on clean water supplies, and the overall economic well-being of a community. A strong intersectionality exists between climate influenced floods and storms and other hazards. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues.

**Drought**

From 2012-2016 California experienced an historic drought, one of six major droughts recorded over the last century in California. California Governor Jerry Brown declared a drought state of emergency in April 2017, which has since been lifted, but with an ongoing mandate to conserve water in the state. Drought impacts, human consumption, agricultural production, hydroelectric production, and other economic drivers for the state. The most recent drought has been estimated to have cost California $10.0 billion, along with the loss of significant jobs. While small compared to the state’s $2.3 trillion/year economy, it was still a significant emergency event for farmers and as it related to environmental impacts such as impacts to fish, and fowl, and impacts to the groundwater.186

Droughts include both minimal precipitation and also high levels of water runoff during rain events. With each successive drought, California has continued to put mitigation measures and adaptive capacity in place (e.g., water banking, conservation methods, alternating to drought resistant crops, et. al.). 187

Climate scientists are modeling future drought based on the North American paleoclimate records.[17] NASA’s modeling in all cases shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states. Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. Extreme rain events will be problematic if increased rainfall is not managed.

**Erosion**

As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe throughout the state. These events can cause erosion or exacerbate areas already experiencing erosion.

**Excessive Heat**

While the ability to predict future heat events at CSU campuses is limited, the effects of climate change may provide some information. Figure below from the Environmental Protection Agency (EPA) depicts the change in temperature over the last century. Areas of Southern California have warmed as much as 3 – 3.5 degrees. Coupled with less rainfall, this may lead to stronger and more frequent heat events, drought, and an increased risk of wildfires.\(^\text{188}\)

![Rising Temperature Change Over the Last Century (EPA)](image)

**Landslides**

The USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.\(^\text{189}\)

**CSU and Climate Change**

**University Climate Commitments**

"Climate change is a global challenge, but local decisions have a major impact. Our cumulative action is what will make the difference for current and future generations."

California is currently and historically a leader on environmental stewardship, and the California State University plays a significant role in our state’s work.”
CSU Chancellor Timothy P. White, (Ex Officio)

As a signatory of the Second Nature’s Climate Leadership Network, a collaboration of presidents and chancellors of colleges and universities in the United States concerned about the increasing pace and intensity of global climate change, CSU agreed to commitments in areas of climate, carbon and resilience. In the context of this hazards assessment, the focus on resilience directly related to on climate adaptation and community capacity-building to deal with a changing climate and resulting extremes. The focus of the higher education leadership is addressing climate change for a “sustainable, healthy, and more prosperous future. Second Nature serves as guidance for campuses assessing their strengths and vulnerabilities in the context of climate change.

In May 2014, the first systemwide Sustainability Policy was adopted by the CSU Board of Trustees, applying sustainable principles across all areas of operations. “The 2014 Sustainability Policy seeks to integrate sustainability into all facets of the CSU, including academics, facilities operations, the built environment, and student life.” In February 2018, CSU issued its first CSU-wide assessment of progress toward the goals outlined in the policy. Findings included: CSU had met and exceeded its 2020 goal for reducing greenhouse gas; systemwide energy use continued to decrease with $128 million in energy efficiency projects since 2005; CSU had met the 2016 water conservation goal of reducing use by 10% and was on track to meet the 2020 goal of 20%. (Findings were updated March 2018.)

Additionally, in June 2017, CSU joined the We Are Still In, a national program that includes college and university leaders dedicated to supporting climate action to meet the Paris Agreements. All 23 campuses of the CSU system participate in the creation of opportunities for students, faculty and staff to find solutions to sustainability challenges and lead in the global effort to fight climate change. Fifteen CSU campus presidents have signed one of the Second Nature Climate Leadership Commitments, the largest initiative to address climate change in higher education.

These campuses have committed to developing climate action plans to achieve carbon neutrality, integrating these efforts not only into facilities design and management but into the institution’s research and curriculum. Eight of these CSU campuses have additionally committed to assessing the institution’s vulnerability and capacity to adapt to the impacts of climate change. These CSU campuses represent 8 of the 11 California higher education institutions that have signed this more comprehensive Climate Commitment, demonstrating the CSU’s clear leadership in the field of climate adaptation and resilience.

191 California State University. https://www2.calstate.edu/csu-system/news/Pages/CSU-Statement-on-Joining-‘We-Are-Still-In’-Climate-Declaration.aspx
Climate Resilience Actions

The CSU campuses face a wide variety of climate-change induced hazards, increasing the risk of the health, socioeconomic levels and over all wellbeing of the campus populations of students, faculty, and staff. For example, hazards such as the increasing heat events, with associated air quality index and impacts on infrastructure systems such as HVAC, create serious and accumulating risks. As a university, much attention and effort has been put on moving the system towards addressing these climate changes. Campus sustainability efforts are demonstrated through initiatives ranging from climate action and adaptation planning, green building, transportation, water conservation, procurement, recycling and sustainable food system. Several campuses across the system are involved in climate action planning. Current CSU policy requires all new construction and major renovations to be capable of achieving a silver level of certification under the U.S. Green Building Council’s Leadership in Energy and Environmental Design (LEED) rating system. While the current systemwide policy does not require projects to pursue LEED certification, several campuses do have such a requirement.

These efforts are directly linked to the essential efforts by campuses to address the shifting local climates that are causing events more severe events than have been experienced in the past and gaining in criticality for influencing decisions regarding mitigation and adaptation initiatives. For example, campuses reported climate related heat and drought mitigation actions related to HVAC systems, drought tolerant landscaping, drought response plans, recycled water, and sourcing of water. Sustainability and resilience concerns of food insecurity (particularly during the COVID pandemic) were voiced in all campus interviews. Efforts to address this growing social equity concern were a variety of initiatives including campus good pantries, campus food partnerships, edible gardens, and direct telephone support lines for students to call for assistance.

For CSU, critical mitigation efforts building upon campus emergency management responses to climate change need to be emphasized as part of an ongoing systematic resilience building effort. These types of efforts often include such actions as community education and engagement to raise risk awareness and promote protective action, identification of vulnerable locations and groups and individuals who may require assistance, and facilitation and support of emergency management research.

CSU Hazard Example

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early
2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.192

Assessing Climate Hazard Risk for Hazard Mitigation Planning

Addressing climate change is a growing requirement in hazards planning and is a critical element in hazards planning for CSU. There is an increasing focus on mitigation and adaptation efforts throughout California and the nation. Climate change affects the emergency management capacity to support preparedness, response and recovery efforts. The complexity of emergency management responsibilities includes planning for the risk reduction to a range of social, technical and infrastructure systems that are affected by disasters (including events induced by climate change) and the need to interact ahead of time to mitigate these impacts. Linking climate change to emergency management allows a focus on these interdependencies of the planning, constructions, and policy, safety decisions, and emergency management exercises.

Managing the complex challenges of these changing environmental condition is coupled with the demands of the University to coordinate data, design the mitigation programs, support emergency management practices and increase clarity on impacts to the students, faculty and staff. As extreme events such as California wildfires increase, so will the demands on those responsible to safety and resilience of the university community. Full-time and volunteer emergency service personnel and supporting organizations will be affected. This requires increased resourcing, including volunteer support, and more creative partnerships between the university and the public and private sectors to meet critical infrastructure needs affecting the campuses.

Many questions can be asked when specifically assessing climate risk. One such approach is the assessment process developed in Australia and published by Coast Adapt. This approach can be used for the CSU system and individual campuses. Information derived from an initial assessment on past hazards in the planning area leads into assessing the system assets or component affected in the past events. Key questions formulate a “first- or second-pass” assessment and series of steps that walk through assessing the situation and analyzing and evaluating risk. Questions include:

- Identify whether any record of occurrence of climatic hazard in the past in the area?
- Are there any risk management strategies in place to tackle any future occurrence of that hazard?
- Identify whether any record of occurrence of climatic hazard in the past in the area?
- What was the consequence of that event (i.e. identify systems that were affected)?

- Are there any risk management strategies in place to protect previously affected systems from future occurrence of that hazard?
- What was the consequence of those events? (qualitative or quantitative estimation)
- Are there any risk management strategies in place to tackle any future occurrence of that risk?
- Understand and identify residual risk of a given system (i.e. risk that remains even after putting a risk management strategy in place)

Figure 3-22: CoastAdapt: How to undertake a climate change risk assessment

For the CSU system, gathering input and to understand campus emergency management staff perspectives of the quickly shifting landscape helps campus decisionmakers identify how climate change may increase existing risks or create new ones and prioritize areas where action may be required. The climate information provides valuable data points for longer range hazard mitigation and climate adaptation planning.

The initial inquiry conducted for CSU offers a high-level snapshot of climate change risks and impacts based on the opinions of the campus emergency managers. While limited, the information helps determine whether a more comprehensive assessment, perhaps in conjunction with the risk management and sustainability offices, may be helpful for the campuses to undertake in the context of emergency management, or to begin appropriately framing a hazard risk informed climate adaptation approach to impending impacts. The information can assist in a number of ways, including:

- Prioritizing mitigation planning decisions.
- Identifying campus systems that need further assessment of risk related to climate changes occurring in the proximity of the campuses properties or communities within which the campuses are located.
- Communicating risks to key campus stakeholders, including students, student families, faculty and staff.
- Identifying who needs to be engaged to further assess climate risks.
- Assessing a broader understanding of the climate adaption options and opportunities for implementation through the hazard mitigation planning process.
- Informing emergency management planning processes and development of operational plans.

Campus Assessments

Campus emergency management representatives and their collaborating campus partners were interviewed to gain understanding of how climate change was impacting their campuses and how climate change was being integrated into disaster management plans and the planning processes. Campus EM interviewees identified the records of occurrence in climatic hazards and if any risk management strategies were in place to tackle the future occurrence of the hazards. Three questions drawn from the CoastAdapt model cited above were drawn from and posed to the interviewees.

- Is there any record of occurrence of climatic hazards in the past in the area around your campus?
- Are there any risk management strategies in place to tackle any future occurrence of that hazard?
- Is climate change an issue of interest at your university?

Data limitations existed for the information gathered. Interviewees gave top of mind responses so responses were often not fully developed, and because of severe interview time limitations, not provided ample opportunity for being well thought out. The experiences shared of the emergency managers are then best informed alongside assessing locally available information and aping into local expert climate knowledge. This assessment does not serve as a risk assessment for climate change or climate change adaptation but the initial offering of insight as to how the emergency management staff and their counterparts reflected on the campus’s evolving hazard risk exposure due to their location’s changing climate-related patterns and the organizational movement towards mitigating the risks.

If an assessment for climate mitigation or adaption is chosen moving forward, it is important to determine the scope, purpose, and timeframe of the planning horizon. The planning timeframe will influence the climate change scenario(s) selected for analysis and which factors will be included in the analysis. When identifying the future climate change risks and opportunities, determine if any existing risk will get worse under future projected changes. Also consider if any new risks can emerge from the future projected changes.

Introduction

Resilience is all about being able to overcome the unexpected. Sustainability is about survival. The goal of resilience is to thrive. Jamais Cascio (San Francisco Bay Area-based author and futurist). In order to succeed, people need a sense of self-efficacy, to struggle together with resilience to meet the inevitable obstacles and inequities of life. Albert Bandura (social cognitive psychologist, Professor Emeritus at Stanford University).

Purpose

The intersection between social vulnerability and risk resilience is an essential concept for evaluating the risks and coping capacities of the rich diversity of CSU campus populations. This section of the HVRA serves a starting point for shedding light on the risks and vulnerabilities of the students, staff and faculty, based on each campus’s unique population and social constructs and inform the overall adaptive management strategies for coping with hazard risks.

The ultimate goal for this high-level assessment is to provide a starting point to further explore the social risks and vulnerabilities for each campus with their unique social
composition and planning efforts. The assessment data inform this process but do not provide the level of accuracy found in a traditional physical risk and vulnerability assessment. A more robust inquiry based on methodical and scientific research-based data is encouraged to gain an accurate picture. Creating such an accurate picture will be an important step in planning for socially based impacts and more accurately identifying opportunities to improve social resilience among all of the CSU community.

This assessment also serves as a platform to encourage campus dialogue, increase resilience capacities, expand the emergency management planning activities, and inform adaptive risk management strategies. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Socially informed mitigation investments move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an integrated education and outreach program unique to the campus. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

Inclusivity at CSU and Social Resilience

Within the CSU system, campus leadership places high priority on environmental justice and cultural competence. These cornerstones serve as a fundamental university ethic. Each campus is committed to providing inclusive and safe environments for all individuals living, learning and working with or on the campus. As one of the most ethnically and racially diverse university systems in the county, CSU campuses are committed to supporting the need of its diverse population of students, faculty and staff. In particular, the campuses take great effort to ensure a lens of equity and inclusion is provided to its historically underserved and first-generation students. Students of color make up more than half of the student population at the CSU with nearly 40 percent alone being Latino. 193 194 195

In keeping with University’s mandate for inclusion and equity, CSU’s hazard mitigation efforts need to be conducted in an inclusive, culturally competent manner. Taking a
whole community approach ensures that all persons within the campus system are assessed and effectively served with fair and equitable treatment.

In order to ensure student success, and continuity of the school’s operations, it’s important to consider a wide range of social factors that potentially influence safe and secure living during “blue sky” periods as well as during a disaster event. CSU prides itself on strongly supporting key populations such as the LGBTQI. Many factors influence an individual’s ability to be resilient and respond effectively to risk. They also influence an ability to return to a healthy functioning campus life after a disaster event has passed.

For effective preparedness, response and recovery to occur, population groups at risk need to have the capacity, skills, and knowledge to understand, access and participate in a meaningful way. In the campus communities, having strong social support networks and active involvement in community disaster responses may impact this process. Addressing the needs, concerns and issues of various population groups throughout the CSU system will better inform emergency management, mitigation planning, complex decision-making processes that leads to financial investments.

Background on Social Vulnerability

Social vulnerability incorporates the traits and conditions that make humans vulnerable (e.g. social structures and inequalities) of the various population in coping with disasters. While vulnerability speaks to the conditions that make populations susceptible to harm, resiliency refers to the ability to coping with and recover from a hazard event—often described as the ability to “bounce back.” When populations lack resilience, their inability to bounce back can significantly disrupt and delay recovery. While every person is vulnerable to risk, individuals from diverse populations, such as those with access and functional needs, are disproportionately more vulnerable and may be at a higher risk to harm to a disaster event. The ability of the diverse populations to respond to unfolding situations may not be the same as more mainstreamed populations. The CSU campus populations are no different.

Presidential Policy Directive 8 defines resilience as the ability to adapt to changing conditions and withstand and rapidly recover from disruption due to emergencies. Presidential Policy Directive 21 expands this to prepare and adapt. Resilience includes “the ability to withstand and recover from deliberate attacks, accidents, or naturally occurring threats or incidents.” Social vulnerability researcher Dr. Susan Cutter and colleagues offer this description: “resilience is the ability of a social system to respond and recover from disasters and includes those inherent conditions that allow the system to absorb impacts and cope with an event, as well as post-event, adaptive processes that

---

196 California State University. Diversity. https://www2.calstate.edu/impact-of-the-csu/diversity/Pages/LGBTQ-Centers.aspx
facilitate the ability of the social system to re-organize, change, and learn in response to a threat.”  

How individuals are imbedded in and supported by their communities also strongly influences one’s abilities to navigate disaster risk and is of particular concern for diverse populations. “Elevated risk factors and inherent social dynamics need to be considered for assessing individual resilience and response capacities and capabilities. Diverse populations with limited or lessened social capital (e.g., networks of relationships among people who live and work in a community) are implicitly at greater risk to harm. Communities with robust social networks are better able to coordinate response and recovery, quickly disseminate information and support physical assistance.”

**Historically Vulnerable Populations at Risk**

Historically, hazard events have more deeply affected vulnerable populations. “There is a general consensus within the social science community about some of the major factors that influence social vulnerability. These include lack of access to resources (including information, knowledge, and technology); limited access to political power and representation; social capital, including social networks and connections; beliefs and customs; building stock and age; frail and physically limited individuals; and type and density of infrastructure and lifelines.”

For socially diverse communities, the emergency management support system can deeply influence that ability to navigate a hazard event. For example, life-saving emergency information delivered in a language that is not fully understandable to students or campus workers due to cultural or linguistic differences, or disseminated through technology and notification systems to which there is limited access due to digital equity in commuter student homes, increases risk. Recent firestorm events have demonstrated the dire consequences when evacuation information and procedures did not incorporate the unique needs.

“…Among the generally accepted [factors that influence social vulnerability] are age, gender, race, and socioeconomic status. Other characteristics identify special needs populations or those that lack the normal social safety nets necessary in disaster recovery, such as the physically or mentally challenged, non-English- speaking immigrants, the homeless, transients, and seasonal tourists. The quality of human

---

settlesments (housing type and construction, infrastructure, and lifelines) and the built environment are also important in understanding social vulnerability, especially as these characteristics influence potential economic losses, injuries, and fatalities from natural hazards.  

populations that the less obvious human connections between natural hazards and the variables that may potentially impact the actions, inactions, or activities of the students, staff and faculty that mitigate the resilience and exposure to natural hazards on the campus.

Research points to the many challenges for those with limited or low socio-economic status during disaster hazard events, including:

- Perception of disaster risk
- Not taken preparedness actions due to it being too costly
- Responding to warning communication due to inability to evacuate or having nowhere to go.
- Housing that is not built or retrofit to effectively withstand hazard impacts
- Lack of adequate resources to address hazard events, resulting injuries and other health related problems
- Difficulty to recover from economic losses due to accessing and receiving aid

Issues such as food and housing security, disabilities and functional needs are among the many social factors that are well known to influence resilience. Others such as low income, gender diversity, sexual orientation, and immigration status concerns influence consistent the availability of support safety nets.

Individuals with low income and limited resources often have increased vulnerability to events due to being less able to afford housing, supplies, medical care and insurance. Age impacts vulnerability. Children and the elderly may have less physical strength and resilience to the event impacts, less financial resources, ability to take preparedness actions prior to and during an event. People with disabilities and access and functional needs can be particularly vulnerable. For example, for those with hearing impairments, they may be unable to receive adequate warnings in time to evacuate. For those with mobility challenges, they may not have access to supportive equipment to access ramps or lifts.

---

201 Susan L. Cutter, ibid. p 245.

While some populations are more readily considered in the emergency management planning process, others have not been. For example, LGBTQI individuals may face challenges of discrimination in shelter environments or concerns regarding issues surrounding disclosure of sexual identities. Transgender individuals may have discomfort with assignments to the appropriate government shelters due to traditional assignments in same sex facilities. Racial and gender discrimination may impact disaster response and assistance due to institutionalized racism. Concerns regarding the lack of documentation of citizenship may influence an individual’s comfort level in asking for and receiving assistance. Gender has historically been a challenge in disaster resilience due to the elements of safety and support during an event, who bears the responsibility of family and added support needs during the recovery, as well as potential challenges of working through bureaucratic system afterwards.

“That social systems play a prominent role in human vulnerability to hazards is central to the idea of social vulnerability. Cutter (1996) describes social vulnerability as including “the susceptibility of social groups or society at large to potential losses (structural and nonstructural) from hazard events and disasters” (p. 530). Commonly used factors to measure social vulnerability include economic, demographic, and infrastructure traits of a community (Cutter et al. 2003). Understanding what drives social vulnerability is an essential step toward helping communities to acquire the resources and strategies needed to minimize losses from disasters.”

For effective preparedness, response and recovery to occur, impacted population groups need to have the capacity, skills, and knowledge to understand, access and participate in a meaningful way. In the campus community, having strong social support networks and active involvement in community disaster responses may impact this process.

The factors examined offered a glimpse into potential challenges to coping capacity and these processes being able to successfully happen. Beginning this exploration of different variables is an important step in understanding the campus social vulnerabilities. For example, gender inequality has long been cited as a characteristic of social vulnerability in disaster response and recovery. Women’s heightened exposure to hazards is attributed to their social class, their caregiving roles, and their relative lack of power and status. Income is another key factor as economically and socially disadvantaged individuals more likely to reside in substandard housing that is at greater risk of damage in a disaster event. Older adults present higher risks for worse health outcomes with increased

---

emergency department visits following disasters, and overall, have increased morbidity and mortality in the post-disaster environment due to factors like preexisting physical and mental illnesses, disabilities, and specific care needs at an individual level. Other social vulnerability factors that may influence such a transitioning system as CSU, and overall the quickly shifting demographic makeup of the State of California, include race and ethnicity due to crisis preparation and information seeking behaviors and culturally appropriate emergency risk communication for low-income minorities.

All of these social issues can be complex and do not always place a person at a higher risk simply because a person falls within a certain social sector or, for example, is dependent upon a wheelchair as a person with AFN. The intersectional nature of what makes an individual’s personal experience and resilience to an event is unique. The role of social capital, an individual’s resilience levels, and the system that supports them all play a major role in risk exposure.

The level of vulnerability of the CSU campus’s faculty, staff and students may be strongly influenced the level of community social capital available to provide various emergency response and recovery needs, such as food, shelter and other types of assistance.

“The social capital component includes measures of social support, social embeddedness, organizational ties, citizen participation, a sense of community, and attachment to place. It has been operationalized through measures regarding rates of two parent households, sports/arts and civic organizations, voters in a presidential election, religious adherents, net migration, and property crime (Sherrieb et al. 2010). Information and communication refer to responsible media, trusted sources of information, and the skills and systems in place for informing the public, as well as communal narratives that allow groups to frame experiences and share meanings. Lastly, community competence speaks to a community’s ability to organize collectively to identify and address problems in ways that are efficacious, creative, flexible, and empowering.”

National Focus on Equity and Inclusion in Disaster Management and the Increasing Lens on Social Vulnerability

---

Ongoing community planning efforts prioritize and elevate concerns for inclusion and equity in disaster response.\textsuperscript{210} This topic has been a key focus for both practitioners and academics for many years and continues to grow in prominence. The National Advisory Council Report to the FEMA Administrator November 2020 describes the issues of equity, cultural competency, and understanding and building social capital as being amongst the most critical challenges facing the field of emergency management.\textsuperscript{211}

California’s current populations is among the most diverse in the nation. Historical influx of immigrants, along with a growing racial and ethnic diversity presents challenges for outreach and hazard mitigation strategies. The population is mobile and aging. These shifts in the social landscape have strong implications for addressing populations risk issues.

Individuals in a local community’s population base who are considered to be more vulnerable to disaster risk have been a critically growing concern for the disaster management community across the state. Importantly, individuals with access and functions needs are disproportionately impacted by disaster events. Individuals with disabilities often need assistance with evacuation, may be unable to see approaching danger or hear announcements to evacuate. Recent wildfire events throughout the state in recent years saw tragic results related to supporting the AFN community as well as those with English as a Second Language. The planning and response efforts for the state’s high-risk populations (also termed as vulnerable populations) came under intense scrutiny during the 2019 auditing of disaster response to recent wildfire events.\textsuperscript{212}

Two bills recently passed in California requiring disaster planning to use culturally appropriate strategies and resources to effectively engage and serve culturally diverse communities and populations deemed to have higher vulnerability to hazards and less capacity for resilience.

\textbf{CA Senate Bill 160 (cultural competency):} Passed on October 2019, the bill requires the plans to address how culturally diverse communities within its jurisdiction are served. (”Culturally diverse communities” includes, but is not limited to, the following: race and ethnicity, including indigenous peoples, communities of color, and immigrant and refugee communities; gender, including women; age, including the elderly and youth; sexual and gender minorities; people with disabilities; occupation and income level including low-income individuals and the unhoused; education level; people with no or limited English language proficiency; and geographic location.) Response actions for climate caused events (and all other) must include culturally appropriate approaches, resources, and outreach in emergency communications, including the integration of interpreters and translators; and emergency evacuation and sheltering. Additionally,

response engagement needs to create a forum for community engagement in geographically diverse locations.

**CA Assembly Bill 477 (access and functional needs):** Passed September 2019, the bill requires that jurisdictions specifically serve the access and functional needs population through the following actions: emergency communications, including the integration of interpreters, translators, and assistive technology; emergency evacuation, including the identification of transportation resources and resources that are compliant with the federal Americans with Disabilities Act of 1990 (42 U.S.C. Sec. 12101 et seq.) for individuals who are dependent on public transportation; emergency sheltering, including ensuring that designated shelters are compliant with the federal Americans with Disabilities Act of 1990 (42 U.S.C. Sec. 12101 et seq.) or can be made compliant through modification and that showers and bathrooms are fully accessible to all occupants.

**Research Methodology**

In this assessment, the interviewers asked campus emergency managers and colleagues about social factors that may potentially impact campus populations. This inquiry was done during the same interview as the campuses were asked about the physical vulnerabilities and hazard risks data. The interviewers asked questions regarding a set of variables known to influence and increased level of risk for social vulnerability.

**Development Guidance**

The social vulnerability variables selected were based on the assessment team experience and guided by informal input and feedback from three prominent social vulnerability experts:

- Susan Cutter, PhD: Distinguished Professor of Geography at the University of South Carolina and director of the USC Hazards and Vulnerability Research Institute
- Lori Peek, PhD: professor in the Department of Sociology and director of the Natural Hazards Center at the University of Colorado Boulder
- Nnenia Campbell, PhD: research associate at the Natural Hazards Center, Deputy Director of the Bill Anderson Fund, and co-founder of the Collaborative for the Social Dimensions of Disasters.

**Data Limitations**

The assessment measured indications of social vulnerability by asking a set of pre-established questions related to vulnerability factors. The social vulnerability assessment data are not definitive or authoritative. The answers and the analysis of this assessment are indicators for increased social risk. This assessment provides indications of increased risk, not accuracy of response nor a true reflection of the situation of a campus. They do not represent an accurate data capture as limitations on the data gathering process influenced the ability to provide accuracy. Limitation factors included:
• **Time Limitation:** Limited time was available for the social resilience/social vulnerability questions during the interview process. Approximately 20 – 25 minutes maximum was allocated at the end of the two-hour interview. The answers were quickly captured, and the interview moved forward.

• **Context:** Lack of interviewee familiarity regarding the connection with, or reason why, the variable was being asked about in context of emergency management/risk reduction. Many times, there was a brief explanation or informational process to explain why the question was being asked along with a brief explanation of the connection to risk and social factor vulnerability.

• **Data Access:** Many interviewees did not have situational awareness and/or access to the variable data so they often provided a best guess. A few gave detailed accounts based on their experience.

• **Research Evolution:** The data assessment process evolved as the interviews progressed. Initial campus interviews were not clearly formatted nor the questions provided with clarity. The initial interviews were more free flowing questioning and the answering. The question format structured formed organically as the research inquiry process progressed. The write up was written as concretely as possible. When questions were not specifically asked or the answers were not provided, the coding “not asked” (NA) was provided on the answer graphs.

• **Limited Staffing:** Many campuses have minimal staffing in the emergency management position, with interviewees serving as a “one-person shop,” responsible for many activities so had little situational awareness of the breadth of the campus populations.

**Interview Approach and Questions**

The assessment began with a brief explanation as to the purpose of the interview questions. Then two sets of questions designed to get high level situational awareness were asked. The first set of questions asked about the populations of concern for emergency management. The second set of questions asked about as set of resilience factors being consider for two planning elements specific to emergency management. At the end of the interview, interviewees were invited to add any additional information or bring up any issue not included in the question set.

**Part One: Campus Populations of Concern**

Interviewees were asked the following: “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning:

- Who has the highest social or physical vulnerabilities?
- Who is most difficult to reach in an event?
- Who has little or limited support networks if impacted in an event?”

Interviewees gave a brief response to each of the three questions. In the campus write up, the questions and answers are listed in two ways; first, displayed as a graphic with icons representing the questions and answers, and second, as a table of the questions along
with the interviewee bulleted responses. The menu of graphic icons below should be used as a reference when reviewing the campus annexes.

Figure 3-23: Menu of icons used to graphically display interviewee answers to the three questions in “Campus Populations of Concern.”
Part Two: Resilience Variables of Concern for Campus Emergency Management

Interviewees were asked the following two questions in relation to a set of 11 variables or groups/issues that might influence social vulnerability:

- Is this factor a particular issue of concern for emergency management on your campus?
- Is this factor reflected in the emergency plans/processes for your campus?

Variables used for the campus surveys:

- Homelessness (housing insecurity)
- Food security (food insecurity)
- Health and wellness
- Disability/access and functional needs (DAFN)
- Racial equity
- Digital equity
- Communications (e.g., planning for ESL, out-of-state, international, special needs)
students/translators...example actions would be resident staff identifying international students and students with disabilities)

- International students
- Immigrants/immigration status issues *(undocumented, DACA, etc.)*
- LGBTQI
- Transportation dependency

The following approach was used to code (rate) the answers to the variable questions. For question one (Is this factor a particular issue of concern for emergency management on your campus?) responses were summarized as **Very High, High, Medium, Low**. It is critical to note that this question was not asking about the issue for the campus as a whole but specific to the concerns for emergency management. The answers were coded based on interviewer understanding of the answer given, along with the system of response averaging, as explained below.

For question two (Is this factor reflected in the emergency plans/processes for your campus?), the responses were summarized as **Yes, No, In Progress, NA**. If there was activity related to plan such as the EOP or to the planning and outreach engagement process, the answer identified as a **Yes**. If the campus interviewee was not linking social vulnerability factors to EM plans or planning process, or didn’t think this was of concern, the answer was given a **No**. If the interviewee was aware of how the variable or issue impacted population risk and emergency management on campus and was actively planning to take action or considering on taking action to integrate into the EM plans or planning processes, then the answer was given **In Progress**. If the question was not asked, or the answer not adequately captured, the answer was given as **NA**.

**Response Averaging**

In order to provide a high-level qualitative response for the answers, the approach of “response averaging” was used. This method was recommended by the social vulnerability researchers who offered guidance on the assessment. If conflicting answers were expressed by the interviewees, the code was averaged out. For example, if one interviewee replied that a variable was not an issue of concern to emergency management (low) and another interviewee replied an opposing response (high), the code was averaged to medium. The response averaging approach supports qualitative answers that offer indicators, not a definitive or authoritative data capture. The purpose is to address disparate responses within a specific campus group of respondents. Specific details of each response were not included in the campus annex write up.

Response averaging was used in the following situations:

**Discrepancy** was expressed between a variable being of concern for the overall campus in general and a concern specifically for emergency management (e.g., answer became medium or NA; if answer was expressed with strong emotions at the campus level but not in emergency management, the answer became medium)
• **Opposing opinions** were expressed amongst interviewees on the variable being an issue of concern for emergency management or currently integrated in the planning process (e.g., answer became medium)

• **Confidence** in the interviewee(s) understanding the relevance of the role/importance of a variable issue or how it impacted the campus for emergency management (e.g., answer became medium or NA)
Table 3-38: Graph of campus-specific emergency management issues of concern and inclusion in emergency management plans and processes.

### High Level Analysis Narrative

Each campus annex includes a brief bulleted summary of any key take away points, elements of interest, issues and concerns, or new work being done. When there were any notable agreements or disagreements if multiple persons were interviewed, this was noted as "in some important areas there were disagreement in answers."

If a particular vignette was described for a campus, it is described at a high level in this narrative section. For example, the interviewee from Chico State expressed concern about transportation dependency during a wildfire. They use the local bus system. They can get students back home throughout the state but then they have no means to get them back to campus. Another concern expressed was that Chico’s outgoing alerts and notification communications are only in English. This limitation is problematic for urgent notification of an impending wildfire to the Hmong staff with limited English skills, who maintain the landscapes.
System-wide Analysis

The following is a high-level narrative summary of social vulnerability assessment (resilience) answers for the overall CSU system. Each individual campus annex provides details on the questions asked, the ratings of social variables, and key takeaways for that campus. This summary reflects a synopsis of key themes, take away points, any major agreements or disagreements, and specific vignettes of the campuses and the system. The narrative follows the interview framework: part one: Campus Populations of Concern and part two: Resilience Variables of Concern for Campus Emergency Management

Campus Populations of Concern

The question asked was the following: “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?

- Who has the highest social or physical vulnerabilities?
- Who is most difficult to reach in an event?
- Who has little or limited support networks if impacted in an event?”

The answers to the three questions asked in part one of the interview tracked closely with ten of the eleven social variables in the question set of the second part of the interview. The one exception variable that was not given was racial equity. While this was not specifically articulated as an answer; it is encouraged that racial equity be considered as a factor in the context of the other answers.

Who has the highest social or physical vulnerabilities?

Populations with Access and Functional Needs (AFN) was repeatedly identified as a population of the most concern by many of the campuses. Some campuses were very specific to disabilities unique to their campus. Northridge, home for the National Center of Deaf Studies, identified the deaf and hard of hearing, describing the physical challenges associated with hearing impairments. Some campuses described emergency planning activities to address this concern. Every semester Los Angeles sends out the list of students with disabilities and where they are located during a Monday through Friday schedule. Humboldt specified students enrolled in their disability resource center. Because the campus has the highest number of students on psychiatric drugs, there is concern about the resiliency and potential coping mechanism of these students, and the needs if students can’t get their medications.

First generation students were cited by multiple campuses as a population of concern. Fresno reported that major of their students are first generation college students who may not have support if significantly impacted and was concerned that their population had a lot of vulnerability without a lot of resources in transportation or technology. Students with lower socio-economic standing that were not resourced well was repeatedly cited by multiple campuses, along with homeless or housing insecure, those who are food insecure, and those without financial stability. San Marcos specifically cited migrant family worker students. Other answers given multiple times though not as consistently as the above were DACA students. Concerns regarding international students were expressed. Pomona included out-of-state students. Sonoma identified students and
staff of the more rural populations due to wind, power outages, being less likely to have running water. Another trending theme was foster populations who are housed in campus residencies. For many of these students, the campus is the only form of housing available to them. Sonoma described their foster population numbers run between 50-100 individuals at a time.

Unique answers came from CalPoly which cited the LGBTQI populations, their very first response to the question, and Monterrey, which identified faculty and staff in employee housing who are leasing or short-term owning on university property and dependent on the WIFI capabilities.

Who is most difficult to reach in an event?

Themes from answers to the first question were reflected in answers to this question including AFN populations, first-generation students from low socio-economic backgrounds, and all those with equity issues who lack technology or are financially challenged without internet access.

Specific issues pertaining to AFN including deaf and hard of hearing students who depended on text to communicate. Sacramento interviewee described the campus as having a high number of hearing-impaired populations and pointing out the deaf studies professors whose offices have doorbells with lights.

Another trending answer was non-English speaking students. Dominguez hills expressed a need to start looking for translation services for emergency notification. Pomona, which sends out all emergency information in English, expressed concern regarding language barriers for their top five populations of Spanish, Arabic, Chinese, Japanese and Korean.

Fullerton described concerns and need to “convince participation” in emergency communications for those students who are undocumented or of DACA status. Technological (digital) inequities were cited in this discussion, along with the challenges faced by the international students because they no social network to fall upon, some have language barriers in crisis and being able to communicate is a problem.

Access was cited in different situations. Humboldt described a communications issue that was unique to their campus and not expressed by other campuses: faculty who have opted out of the RAVE system. RAVE text message and alerts are an opt out – so there is concern for those not receiving the messages. While few students have opted out, but many of the faculty have. At the other end, San Marcos felt this was not an issue for their campus with everyone preloaded into the emergency coms system and the system is an opt out. Sonoma have faculty and staff who either haven’t updated their information for emergency communications or live in the rural areas outside of the incorporated areas.

An issue identified by Long Beach, primarily a commuter campus, was how to reach individuals before they get to the campus, as they don’t have reliable communications. Northridge also described a challenge in contacting commuter students and getting the message out to them on their way into campus.

An issue of access to the students because of which platforms the target audience was using was identified by two schools. East Bay expressed concern over students who don’t
read emails. Since they read text, they have had to strategize and prioritize since everyone uses a different method but felt this was an issue. CALPOLY identified the challenge of reaching students whose social media platforms are primarily Instagram and snapchat.

A unique audience challenge was expressed by Monterrey where the concern was not the students, faculty or staff but “partners.” Partners are other people who lease facilities across the campus for storage and for the contracts depts. EM doesn’t have a list of these renters and would need to notify property management contacts. They have emails for residential renters.

Who has little or limited support networks if impacted in an event?”

Answers to this question generally followed trending themes of the earlier questions: residents in the housing populations who had no place else to go (e.g., those in or who have come out of foster care system), individuals with little or no access to nutrition or technology, homeless, socio-economically disadvantaged, first-generation students, international students, and those with English as a Second Language (ESL). Monterrey identified those with concerns of mental health support (note the similarity to the answer given by Humboldt to the first question).

Two responses provided additional insight. Sacramento identified Dreamers/DACA students as a result of immigrations issues with parents whom they were living with off campus. Sonoma County cited those who rely on student housing and are middle income students are “making it work until they can’t.” Interviewees noted that they are reaching out to those students on these issues. Dominguez Hills interviewees shared there was a need for a “plan b for housing.”

It should be noted that individuals with AFN were not given as an answer to this question.

Resilience Variables of Concern for Campus Emergency Management

Homelessness (housing insecurity)

Several campuses voiced general campus concerns regarding growing issues of housing insecurity for their students. Couch surfing and sleeping in cars were heard in some of the answers. The challenges may come from reduced job security and not being in dorms during times of COVID. Some campuses described active outreach and programs for supporting students. Few described actively incorporating elements of homelessness in their EM plans or planning process outside of an event response. For example, Stanislaus described their Homeless program for those who are vulnerable, where they house them in housing dept and provide rooms that allow them to stay for 30 days. They also provide them with community outreach to get them back on their feet. This was cited as a low issue of concern and not reflected in their EM plans or their planning processes.

Food security

Food security came up as a strong, ongoing issue of concern for most of the campuses. Many described how the food pantries had been forced to shift operations during COVID. Most had adjusted operations but continued to provide food, while some had stopped all
together. Some campuses responded that this was not of concern due to excellent, readily available food pantries off campus. However, campuses such as Dominguez Hills, located in a very low-income area, expressed a very high concern about the issues but had not yet had a chance to address it in the plans or planning processes. Overall, addressing food security was not a regular part of the EM planning process or included in the plans.

Health and Wellness

Concerns regarding health and wellness were consistent throughout the campus system ranking from very high to not of concern to EM due to the active process of addressing the issues on the campus by the health centers. In early interviews they were asked if there was a spike in issues due to COVID to which many responded yes. At the very onset of the interviews, a question was asked about increased suicide attempts, to which there were affirmative responses. This question was stopped when the questions became focused on the impacts of the EM plans and processes and not just generally. Some campuses responded to the active engagement with their other centers.

There were several explicit examples given for this variable. When Sonoma State anticipates events, the director of psych and counseling is part of their EM response planning. SONOMA CARES, developed in the 2017 fires was cited as a program to connect students with counselors during a crisis. They also addressed the faculty and had counselors on call to come into the EOC. They also bring in mental health into the response plan. Stanislaus described seeing a spike in mental health issues now. They have representatives on their infectious response team and in the EOC and talks all the time with county EOC. They have counselors available through telehealth services. Also, the Employee Assistance Program (EAP) and encouraging engagement because the isolation is affecting people. They are actively working this in their planning process so were listed as an In Progress. Dominguez Hills described this as “definitely, a very high” issue of concern. For their campus, it is treated like an EOC branch, having developed 6 Toro Teams to address employee success and wellness and have a chair to set up online platforms. They’ve opened up to expand to students; this effort has never been done. When asked if it was reflected in plans, the answer from the emergency manager, was yes, it is “Nora’s Plan” and is In Progress, as it currently sits in the campus COVID safety and response plans but at some point, the plan will transition to the EOP. The issue around health and welcome was identified as a strong need for the campus, and the group reports up to the EOC, whose structure has been a “lifesaver.”

Disability/access and functional needs (DAFN)

Of all the variables, this one generated the most consistent response. This population group ranked among the highest of those populations of concern generally and for communications outreach in the part one question set. All campuses responded positively when asked about their inclusion of AFN in the EM process and plans, as it is a mandated element for emergency management. There were different responses on how they include it into the plan. Some responded that it was “baked” throughout the plan
while other campuses described AFN as being a specific annex. Many campuses actively engage their campus community in AFN preparedness activities by including AFN association/support representatives in EOC and general EM planning activities, meeting with and training residential hall leaders, asking guidance from campus support services, and incorporate AFN activities in their exercises.

Racial equity

This variable was added as a late addition question after being strongly encouraged by the informal social vulnerability research advisors. Of all questions asked, this variable resulted in the least amount of concern specific to campus emergency management or was racial equity included in the EM planning processes and plans. In some circumstances, the interviewees expressed disagreement amongst themselves regarding racial equity being an issue for EM on their campus. Some campuses referenced the racial issues in context for their campus overall but not in relation to EM. One campus noted racial equity issues pertaining to national social strife resulting campus protests and demonstrations were more associated to security and policing.

Humboldt State was the only campus that responded racial equity was actively on their emergency management radar due to the ongoing, just off-campus demonstrations that continue to place a couple of years since the (off campus) death of a student of color. Campuses located in low-income communities expresses more concerns regarding the variable and the ways in which they felt they needed to address it in their planning processes. Dominguez Hills was the only campus which cited this being a “very high” issue of concern. The campus emergency manager expressed a strong desire to address the issues pertaining to racial equity at some point in the future.

Overall, there seemed to be an underlying lack of understanding on how the variable directly pertained to the EM efforts. Some campus interviewees asking for further explanations on why the question was asked and clarifications how could (or should) racial equity be incorporated. Further, the emergency management incorporation of racial equity and providing a stronger connection for planning for racial diversity inclusion demonstrated itself to be an opportunity for improvement.

Digital equity

In addition to question regarding AFN, response to this variable consistently ranked high on the radar for all campus interviewees. Most campuses had not included digital equity in their EM plans and processes, though some campuses noted that they now realized that the variable needed to be proactively addressed in EM planning documents and in the planning processes. Some noted the issue was adequately addressed in campus continuity plans. As an issue of concern, digital equity was noted as high or not being of key concern because of the proactive efforts of the IT department during the recent COVID period. Consistently, the campus interviewees expressed admiration and utmost respect for the work of their campus leadership, administration and IT departments in the quick response to extensive, and often complex, needs of many students who needed digital equity support. Many interviewees provided exact details of how the campus had
responded to supplement needs for those students who did not have access to ensure continuity of education. It was noted that there were differing perspectives on providing expanded campus access to digital support (e.g., parking structures). While some expressed concerns on the ability of students to access support elements such as WIFI connection on campus facilities during high heat days, other interviewees expressed security concerns about expanded access due to criminal activity or use by off campus individuals.

**Communications**

This variable was explained as planning for ESL, addressing the needs of students out-of-state or country or AFN populations. This variable trended to interviewees expressing their concerns that their campus systems distribute their alerts and warnings in English only and there was a strong need for multiple languages being incorporated in the outreach, particularly for rapid events such as a wildfire. Such was the case for Chico State, one of the campuses that issues English only communications. Chico cited a concern being the Hmong staff is a growing population on the campus landscape staff and during a rapidly moving wildfire event, reaching them in an understandable way would be an issue of concern. They are in process of addressing this issue. For campuses in a highly ESL environment, the communications being only English was cited of concern. Dominguez Hills described it as being of Very High concern for their non-English speaking community and they were “not doing enough to address any of that.” While it is not reflected in current plans or the planning process, interviewee Nora Garcia reflected “boy do I have plans for them!”

**International students**

The questions related to international students and immigrant/immigration status issues were merged into one variable at the beginning of the interview process. Later it became evident that two distinct variables were needed due to the different responses that were given. For the international students, campuses trended towards expressing proactive engagement for active campus with support, supplemented with active leadership from the Chancellor’s Office on issues for the international student populations. Few campuses noted it as a high issue of concern for EM or have included it in their EM plans and planning processes. Channel Island reported a two-page annex in their planning documents. When Chico State was interviewed, the two variables were still merged as one. Chico responded that they have a small population of students international but that the office is integrated into the emergency, State Department protocols are documented, and the information is in the EM system. Therefore, the issue was of low concern due to it being addressed in their plans.

**Immigrants/immigration status issues (undocumented, DACA, etc.)**

This variable, once separated from the international students, trended towards very mixed responses. Many did not express immigrants, as being an issue of EM concern. Some did express certain immigrants, particularly DACA students, as being of high concern, but had not actively addressed immigrants/immigration status issues in their EM
plans or planning processes. Stanislaus described issues with DACA students because they have “lots of children of migrants.” They expressed this variable as a medium issue of concern and had not included it in the plans or processes. Bakersfield reported that it actively engages on immigration issues in their EM planning processes, have representatives from immigration center in their EOC group, and actively “go to them” (dreamer center) every semester for discussion. Dominguez Hills expressed this as a very high issue of concern. Reference was made to how the revoking of a related presidential order a couple of months before the interview created concerns over potential civil unrest and reflections on how it could negatively impact the EM program. Most campuses did understand the growing significance of this issue as it pertain to EM while some campuses did not see the specific connection with EM planning.

**LGBTQI**

This variable invoked widely varying responses as it pertained to the relationship between issues of the LGBTQI community and emergency management. Some campus representative inquired as to how the variable connected to EM, while some interviewees made it clear that LGBTQI concerns were not to be considered in their EM planning since everyone is seen as the same and treated equally. For other campuses, this variable had been thought out.

Bakersfield incorporates LGBTQI in its EM plans and has a consideration in sheltering, plans to place one person per room in a shelter/off campus. San Marcos EMs actively engage with the campus LGBTQI community on emergency management concerns, proactively address issues and concerns of the community, and integrate the variable in their emergency plans and process. In their planning and community outreach, San Marcos EM meets with LGBTQI groups annually to review EM processes and discuss EM procedures and discuss their specific vulnerabilities. More specifically, they look at the issues of the community members “being targeted” in their spaces and talk about what to do if there is a lock down. When the first interview question was posed asking the campus to cite their top communities of concern, CAL POLY cited LGBTQI community as their first response. As it being an issue of concern, they rated it high, and mentioned the outspoken leadership of the Dean of Students on the topic. They cited the abundance of LGBTQI organizations working to improve diversity (and champion racial equity) and shared that they all contribute to the emergency planning efforts through designated liaisons, task forces and planning groups.

**Transportation dependency**

This variable was addressed in some degree by most campuses, either through a transportation annex associated with their EOP or in evacuation planning efforts with the other campus departments. There are many circumstances that impact the transportation issues for the different campuses: some students travel from far away and come by bus or family cars, some are car dependent but more local, and others rely on local public transportation.
Los Angeles reported transportation dependency is an issue of concern because the campus is a heavily commuter campus with Metro Link adjacent to the campus. Many who work and study on campus rely on public transportation and are provided incentives. It is a problem when public transport is down or when risk is involved, such as in COVID. They have addressed the variable in their plans, as did Channel Islands, which cited transportation as a very high issue of concern and have addressed it in evacuation plans. For their campus, a number of a number of individuals experienced with transportation issues a couple of years ago during the fires. Their representative is now part of the county’s EM transportation planning effort, and the soon to be released plan includes CSU which will help the campus relieve the issues, if evacuated. Some issues on transportation dependencies were unique for those campuses where students commute from long distances, Chico State being one. At Chico, students come from a long way away. If they have to close the campus for situations such as bad AQI, and they need to evacuate, they will be asking students to go home. The issue is the time for the student’s support network to get them and concern about when to tell them to come back to campus. They have MOUs with bus contractors and are working with school districts such as Tahema county in order to move them to an evac site close.

**Linking Campus Social Resilience and Hazard Vulnerabilities**

This section brief introduces to the link between socially vulnerable populations and a particular hazard. Extensive research has been conducted on the impacts of hazards on the general population. Not all linkages have been documented or published regarding all hazard impacts on each specific population described in this document. Researching and detailed scholarly research on those linkages are beyond the scope of this assessment.

It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded. In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.
Geological

Earthquake

Impacts on populations from earthquakes are complex, with long term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.213

Landslides

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied buildings which makes it a function of structural vulnerability and therefore, indirect. The degree of vulnerability to landslides by an individual considered at high risk, or even the general populations, also depends on human behavior, including many of the traditional

social factors that are difficult to measure such as situational awareness, prior knowledge of hazards, and decision-making capabilities.214

**Volcanoes**

There has been limited analysis on the full social and economic impacts of volcanic eruptions, but known impacts show extensive disruption to livelihoods, through evacuation or destruction of land and resources. Typically, indirect fatalities happen across even longer time scales than primary fatalities, and so social processes associated with wellbeing and secure livelihoods are even more likely to be a driver for risky behavior.215 Access to warning systems or neglecting warning system impact decisions to leave. A volcanic eruption can impact health. Ashfall from volcanoes contain carbon dioxide and fluorine, gases that can be toxic to humans, and can collect in volcanic ash. The resulting ashfall can lead to crop failure, animal death and deformity (impacting financial security for those dependent on farming), and human illness. Ash's abrasive particles can scratch the surface of the skin and eyes, causing discomfort and inflammation. Further effects are the deterioration of water quality, fewer periods of rain, crop damages, and the destruction of vegetation. During volcanic eruptions and their immediate aftermath, increased respiratory system morbidity has been observed as well as mortality among those affected by volcanic eruptions. Health hazards can range from minor to life threatening. Exposure to acid gases such as sulfur dioxide, hydrogen sulfide, and hydrogen chloride can damage eyes and mucous membranes along with the respiratory system and, under extreme conditions, can lead to death.216

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California's major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.

---

- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.

Hydrogen halides can coat ash particles and once deposited, poison drinking water, agricultural crops, and grazing land.

**Water**

*Dam and Levy Failure*

Risk from dam and levy failure are infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

*Erosion*

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

*Landslide*

Risk from landslide relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

Landslides can result in primary lifeline failures through the loss of roads or power and communication lines. Transportation routes are often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods.

*Sea Level, Tsunami*

Tsunamis can leave individuals homeless and without resources after an event and be psychologically damaging long term. The contaminated water and food supplies pose a risk to people’s health. Flood waters can carry many sources of contamination such as dirt or oil, and infectious diseases.

Risk from tsunami and sea level rise are secondary impacts relating to, water inundation, infrastructural losses, and changes in hydrology and land use. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, access to alerts and warnings, cultural understanding of the alerts and warnings, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to other social factors.
Tsunamis can destroy homes, change landscapes, seriously impact local economies, spread disease and kill people living within the tsunami inundation zone. The threat of disease comes from a mix of fresh water, sewage and salt water. The force of the tsunami wave may kill people instantly or they may drown as water rushes on the land. People are killed through flooding, hit by floating debris or being thrown into buildings and walls. Additionally, there threat of collapsed buildings, electrocution and explosions from gas and damaged tanks. Those impacted often suffer psychological problems such as PTSD afterwards.\textsuperscript{217}

For sea level rise, the water finding its way to farms and reservoirs can harm drinking water and the ability to grow crops, impacting those financially dependent on farming. It exacerbates the issues related to increased severity of storm-surge events. Research is now seeking to better understand the serious risks posed by SLR and the potential for socially vulnerable populations to be disproportionally impacted by these risks. One analysis indicated that many socially disadvantaged Americans living in coastal areas are very likely to be disproportionately affected by SLR. “While there have been significant research efforts focusing on the distributional and equity aspects of greenhouse gas mitigation policies, such as carbon taxes and revenue redistribution schemes (BEJEAP 2010), there has been less focus on distributional implications of impacts, and even less on distributional implications of adaptation actions.” \textsuperscript{218}

\textbf{Flood}

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. \textsuperscript{219}

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other

illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural health and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, sadness and grief. Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

**Severe Weather**

**Tornado/High Wind**

Public health risks and impact of tornadoes in these settings are not well investigated with mainly studies focused on death and injury. Wind speeds from tornadoes and high winds can destroy buildings, cause automobiles to become airborne, and turn debris into flying missiles. When sucked up into the winds. Impacts from tornadoes and high winds are known to damage and destroy mobile homes, often built with lighter-weight materials than regular houses, and much more affordable and therefore financial accessible for individuals on limited incomes. Children and older adults may be at a greater risk of death and injury due to pre-existent medical illnesses, poor mobility, decreased ability to respond to tornado warnings, and greater susceptibility to injuries. More social vulnerability work is now examining linkages between risk and lack of understanding of risk communications, such as alerts and warnings. The issue of language barriers as well as access to hearing an alert put communities at higher risks as tornadoes can strike quickly with little or no warning, giving those in impacted areas barely enough time to take shelter. Individuals with mental health issues may be at higher risk. Because of the unpredictable nature of tornadoes and severe storms, it’s normal for people to experience emotional distress. Feelings such as overwhelming anxiety, trouble sleeping, and other depression-like symptoms are common responses to these types of disasters. Symptoms of distress may appear before, during, and after a tornado or severe storm and may manifest in the hours, days, weeks, months, or even years after the storms occur. For individuals in high places of risk, in substandard housing, and limited financial support, these events may impact on a short- and long-term basis.

**Hail**

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where

---

greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitoes that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.
Cold

Research shows that excess morbidity and mortality occurs during cold weather periods. We critically reviewed evidence relating temperature variability, health outcomes, and adaptation strategies to cold weather. Health outcomes included cardiovascular-, respiratory-, cerebrovascular-, and all-cause morbidity and mortality. Individual and contextual risk factors were assessed to highlight associations between individual- and neighborhood- level characteristics that contribute to a person’s vulnerability to variability in cold weather events.

Skin exposure to cold weather may render one susceptible to adverse health outcomes. Respiratory tract infections are more likely to occur during periods of low temperatures and low humidity. Socioeconomic indicators related to morbidity and mortality do not appear to strongly contribute to a person’s susceptibility to cold weather. However, the role of socioeconomic status is not clear as some evidence implies that income disparities and fuel poverty contribute to cold-related mortality.

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices. This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underly tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes. It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases. The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6° F. Hypothermia occurs when your body temperature falls below 95° F. As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Wildfire

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. \(^{224}\) Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.\(^{225}\)

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs. \(^{227}\)

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy. \(^{228}\)

Drought

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\textsuperscript{229} Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\textsuperscript{230} Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events. (sac annex)

Hazmat

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

Potential Impacts of the Hazard

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment.

Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people

- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease.

231 Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate. 232

directs specific funds to be spent on emergency preparedness campaigns and outreach focusing on “California’s most vulnerable populations, including the elderly, disabled, and those in disadvantaged communities.”

The term “disadvantaged communities” along with a state focus upon them began with AB 32 (California Global Warming Solutions Act of 2006. AB-32. 2005-2006 (2006), which directed the public investment associated with that bill towards “the most disadvantaged communities in California.” This term was further defined in SB 535 (California Global Warming Solutions Act of 2006: Greenhouse Gas Reduction Fund. SB-535. 2011-2012 (2012) which stated:

“The California Environmental Protection Agency shall identify disadvantaged communities for investment opportunities related to this chapter. These communities shall be identified based on geographic, socioeconomic, public health, and environmental hazard criteria, and may include, but are not limited to, either of the following:

- “(a) Areas disproportionately affected by environmental pollution and other hazards that can lead to negative public health effects, exposure, or environmental degradation.
- “(b) Areas with concentrations of people that are of low income, high unemployment, low levels of homeownership, high rent burden, sensitive populations, or low levels of educational attainment.”

The second consideration was a desire to unify the focus here with other actions already undertaken by the State to address hazard vulnerability. This importantly includes the information contained in the 2018 State Hazard Mitigation Plan. This plan was developed by the Governor’s Office of Emergency Services and gives guidance to hazard mitigation efforts in the state. It includes a hazard vulnerability assessment based upon a

231 https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/
consideration of major hazard event types and socio-economic and demographic characteristics related to vulnerability and resilience.

The social vulnerability index used in the 2018 SHMP is of particular interest in the context of this work. Social vulnerability was there described as representing “the cumulative influence that socio-economic and demographic characteristics exert on differential hazard outcomes.” The social vulnerability index included in the 2018 SHMP can therefore also be used in the identification of disadvantaged communities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Communicable Diseases**

Next Steps

The indicators and reflections in this assessment provide a valuable starting point for further honing the stakeholder engagement process and gathering stakeholder input. It offers guidance for conducting educational outreach. Offering emergency management presentations and distributing information packages to the different groups listed in the assessment may be a valuable option. For example, outreach to campus’s LGBTI organizations, as is being proactively conducted on one campus, may be a financial investment worthy of consideration, if that need were appropriate for the campus. Gaining accurate situational awareness will guide the determination of mitigation measures targeting the social demographic needs and existing social capital support on campus. This requires thoughtful research, and inclusive approaches to drive the investments for the campus’s unique community.

4.1 University Profile

University History

Following the creation of the California State Colleges system, Bakersfield was selected as a site for a new four-year university. The school was established as Kern State College in 1965 and founded as California State College, Bakersfield (CSU Bakersfield) in 1968. Twenty years later, the school was granted university status and adopted its present name. Today, the school includes four colleges and is classed as a Master’s College by the Carnegie Institute. In 2015, CSU Bakersfield was selected for the Carnegie Foundation for the Advancement of Teaching’s Community Engagement Classification, recognition for exemplary institutionalized community engagement. It is designated as a federally recognized Hispanic-Serving Institution (HSI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The Academic Senate recommends to the president policies and procedures that support the university’s mission. It consists of twenty-four members, twenty of whom are elected faculty. There are four committees of the Senate which support academic affairs, faculty affairs, student services, and budget and planning.

The division of Business and Administrative Services on campus is responsible for fiscal and support services, facilities management, and safety and risk management.

University Mission

“CSU Bakersfield will be a model for supporting and educating students to become knowledgeable, engaged, innovative, and ethical leaders in the regional and global community.”

CSU Bakersfield outlines five goals in support of their mission and vision. The priorities are directed towards strengthening and advancing faculty, staff, and student success and learning; working together with the community to address regional needs; diversifying and stewarding campus resources; and developing high-quality academic programs and supports.

University Location

The CSU Bakersfield main campus comprises 375 acres in the city of Bakersfield, home to 350,000 residents. Located in central California in the San Joaquin Valley, the campus and
city are found in one of the most productive agricultural (by value) and oil-producing counties in the United States. City limits extend to the Sequoia National Forest, at the foot of the Greenhorn Mountain Range, and to the Temblor Range, behind which is the San Andreas Fault. Along with the main campus, CSU Bakersfield operates a satellite campus in Lancaster, CA, CSU Bakersfield - Antelope Valley (CSUB AV).

**University Population**

Typically, enrollment at CSU Bakersfield falls slightly above or below 10,000 per semester. In fall 2019, the 11,200-student population was overwhelmingly made up of undergraduate degree seekers, 78% of whom are under the age of 25. Hispanic students make up 63% of CSU Bakersfield students, with white students making up the second most populous group at 16%.

In addition to the student population, the University is home to 1,277 employees, 50.6% of whom are faculty.

**4.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment**

**Requirement §201.6(c)(2):** The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

**Requirement §201.6(c)(2)(i):** [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

**Requirement §201.6(c)(2)(ii):** [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

**Requirement §201.6(c)(2)(ii):** [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

**Requirement §201.6(c)(2)(ii)(A):** The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

**Requirement §201.6(c)(2)(ii)(B):** [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate...

**Requirement §201.6(c)(2)(ii)(C):** [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.
Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

4.3 Hazard Identification and Risk Assessment

Overview of California State University, Bakersfield History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Bakersfield Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 4-1 (following).

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely**- 76%-100% that the hazard would occur annually.
- **Likely**- 50%-75% that the hazard would occur annually.
- **Possible**- 11%-49% that the hazard would occur each annually.
- **Unlikely**- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent.\(^1\) They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions.\(^2\) The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.\(^3\)

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague).\(^4\)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 4-2 following).

*(Source: Interviews with CSU campus staff at CSU campuses and at CSU Chancellor’s Office.)*

**Descriptions of Identified Communicable Disease Hazards at CSU Bakersfield**

CSU Bakersfield (CSUB) has identified two (2) communicable disease hazards that have had the greatest impact on campus – COVID-19 and meningitis. The following are brief descriptions of the two (2) communicable disease hazards at CSUB.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus
spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It’s not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.5

**Meningitis**

Meningitis is an inflammation of the fluid and membranes (meninges) surrounding the brain and spinal cord. The swelling from meningitis typically triggers signs and symptoms such as headache, fever and a stiff neck. Early meningitis symptoms may mimic the flu (influenza). Symptoms may develop over several hours or over a few days.

Most cases of meningitis in the United States are caused by a viral infection, but bacterial, parasitic and fungal infections are other causes. Some cases of meningitis improve without treatment in a few weeks. Others can be life-threatening and require emergency antibiotic treatment. Bacterial meningitis is particularly serious and can be fatal within days without prompt antibiotic treatment. Delayed treatment also increases the risk of permanent brain damage or death.6

**Location of the Hazard**

Communicable diseases have the potential to affect the entire CSU-Bakersfield planning area equally. As a result, the communicable disease hazard can be found at both the CSU Bakersfield (CSUB) main campus in Bakersfield, CA (Kern County), as well as at the CSUB-Antelope Valley satellite campus in Lancaster, CA (Los Angeles County). Because of the ubiquitous nature of many communicable diseases, students, faculty, and staff at both CSUB locations are at risk of exposure to the communicable disease hazard.7

---

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs at CSU-Bakersfield, approximately 560 students, or 5% of the CSU-Bakersfield total enrollment of 11,199 will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. 8

Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard.

Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 4-1 describes the different BSLs and provides examples of communicable diseases that would typically fall into these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.
The Extent of CSU Bakersfield Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Meningitis at CSU-Bakersfield. Meningitis would be classified at the BSL-2 containment level.\(^8\,9,10\)

The Extent of CSU Bakersfield COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.\(^11\)

History of the Hazard

Over an approximately one-year period, from mid-March 2020 to March 23, 2021, there were a reported 148 cases of COVID-19 at CSU-Bakersfield. CSU-campus-specific COVID-19 case data for CSU-Bakersfield can be found in the *History of the Hazard* section below.

Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a

---

A geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Figure 4-2: County-Level and Campus-Level COVID-19 Case Data

Figure 4-2 shows County-level and campus-level COVID-19 Case data for CSU Bakersfield. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates, as the figure reflects the date shown from the CSU-Bakersfield COVID-19 Dashboard.)

</tbody>
</table>

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the CSU-Bakersfield campus. The extent of this impact is contingent on the type of infection or

---

contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contracts communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU - Bakersfield students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU – Bakersfield) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

---

Table 4-4: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 4-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall into these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

---

### Table 4-5 Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one’s hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

17 CDC/National Institutes of Health. *Biosafety in Microbiological and Biomedical Laboratories, 6th Ed.* Print. Retrieved 05.03.2021 from: [https://www.cdc.gov/labs/BMBL.html](https://www.cdc.gov/labs/BMBL.html)
Anthrax
West Nile Virus
SARS Virus (Including COVID-19)
Tuberculosis
Typhus
Yellow Fever
Hantaviruses
Avian Flu

These bacteria and viruses cause severe to fatal disease in humans, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

H5N1 (Bird Flu)
Dengue
Hemorrhagic Fever
Marburg Virus
Ebola Virus
Smallpox
Lassa Fever
Crimean-Congo Hemorrhagic Fever
Other Hemorrhagic Diseases

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

Probability of Future Occurrence of the Hazard

There have been cases of Meningitis at CSU-Bakersfield. However, there are significant data limitations regarding meningitis disease cases, as the information is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazard like meningitis. However, based on the limited data, we can present qualitative probabilities of future occurrence (Table 4-6, 4-7 below) based on ranges of communicable disease frequency.

Table 4-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:
Table 4-6: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s system-wide probability ranking (below) reflects the ranking at the individual CSU campus level unless noted otherwise.

Note: For CSU-Bakersfield, there is a higher probability of future occurrence of meningitis than CSU-system-wide, as there has been a previous outbreak of the disease on that campus.

Vulnerability to the Hazard

Vulnerability to a communicable disease hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the CSU - Bakersfield campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, CSU - Bakersfield had 11,199 students as well as additional staff and faculty.18,19 Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out in the current COVID-19 pandemic on the CSU – Bakersfield campus.

Estimate of Potential Losses

The COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU – Bakersfield) are at risk of developing an extreme incidence of

18 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

COVID-19, and may become “super-spreaders” for adjacent communities.\textsuperscript{20} The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 4-5 below for the economic impact to the CSU – Bakersfield campus). Several CSU campuses saw refund losses surpass $10 million. (See Figure 4-5.)

**Mitigative Relief from Federal Assistance**

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of

mainly empty campuses. (See Table 4-8) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Note: See Table 4-8 for Relief figures for the CSU – Bakersfield campus.

</table>
Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 4-9 below for the “10% outbreak scenario” projections for the CSU – Bakersfield campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students)*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system including CSU - Bakersfield. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.
Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).
**Dam and Levee Failure**

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtopping to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

---

Location of the Hazard

Kern County is home to a variety of flood control facilities and levee systems throughout the Bakersfield region including along the Kern River. The Kern River drains the southern Sierra Nevada Mountains and Isabella Lake into the southern San Joaquin Valley. The Kern River Watershed is fed by snowmelt from the mountains near Mount Whitney and to the south.

The Kern River feeds into Isabella Lake, a reservoir created by the Isabella Lake Dam. The dam is a US Army Corps of Engineers dam in the mountains 50 miles east of the CSU Bakersfield campus. The Kern River flows down through the canyons below the dam and through Bakersfield before reaching the campus. There are three diversion dams on the river downstream from Isabella Lake Dam and upstream from the campus. The CSU Bakersfield campus is situated across from Stockdale Highway separating the campus from the southern bank of the Kern River. The distance from the river to the campus boundary is less than 1,500 feet.

Levees have been constructed to protect the banks of the Kern River as the river extends through Bakersfield. Levees are also used in containment of diversion channels and irrigation aqueducts. The CSU Bakersfield campus is located within a designated levee protected zone identified in the Kern County Multi-Jurisdictional Hazard Mitigation Plan.
Figure 4-6: Dams and Levees near Bakersfield
Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- High hazard potential dams may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- Significant hazard potential dams are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- Low hazard potential dams are not expected to result in loss of like, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

</tbody>
</table>

The Isabella Lake Dam was constructed to provide flood protection to Bakersfield and to provide storage of domestic and agricultural water to the region. The dam is subject to potential seismic activity as known fault lines extend near the dam including the Kern Canyon and Lake Isabella faults.

The CSU Bakersfield campus lies within the inundation zone of the Isabella Dam. In the event of a catastrophic failure of the Isabella Dam, the CSU Bakersfield campus is expected to experience peak inundation depths of 4-5 feet. The campus is expected to be impacted by one foot of water within 8-10 hours from the time of dam failure. The time between dam failure and arrival at the CSU Bakersfield campus should allow for sufficient time to evacuate the campus. The flood inundation zone from an Isabella Dam failure covers a large portion of the region requiring evacuations to occur over long distances.

Members of the campus community who reside or are employed in these areas would be most impacted. This specific hazard would substantially alter the ability of the campus to maintain operations as damages would be extensive, the campus community would be heavily affected with the loss of life and homes, and student financial capacity to support ongoing education being diminished. Based on the factors above, the planning committee ranks the extent of the hazard as **Moderate**.

**Extent - Levee Failure**

Levees are used along numerous irrigation channels and other waterways in Bakersfield including the Kern River. The southern bank of the Kern River is lined with a levee protecting much of east and south Bakersfield. The CSU Bakersfield campus lies within a levee flood protected area. In the event the Kern River was flowing at elevated levels and a failure of a levee were to occur, the CSU Bakersfield campus would likely experience flood related damages. This specific hazard would substantially alter the ability of the campus to maintain operations as damages would be extensive, the campus community would be heavily affected with the loss of life and homes, access to campus would be limited, and student financial capacity to support ongoing education being diminished. Based on the factors above, the planning committee ranks the extent of the hazard as **Moderate**.
History of the Hazard

California has witnessed only a small number of dam failures over past half century. **There have been no occurrences of dam failures in Kern County. However, there have been instances of various levels of dam compromises in Kern County.**

- April 27, 2006, seepage was identified at Isabella Auxiliary Dam.
- May 2006, heavy precipitation and melting snowpack caused Lake Isabella to fill faster than release capacity. High water levels caused flooding around the lake.

California has an extensive network of levees primarily throughout the Central Valley. These levees have been constructed using a variety of methods and often were built decades ago. Statewide, levee failures have occurred more frequently than dam failures. **In Kern County, there have been the following instances of past levee failures:**

- 1905, Buena Vista Lake levee breached resulting in damage to 12 miles to railroads and 25,000 acres flooded.

Potential Impacts of the Hazard

**Dam Failure Impacts**

Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Potential impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

---

Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

Probability of Future Occurrence of the Hazard

Kern County remains at risk from dam and levee failure. The location of the CSU Bakersfield campus downstream from the Isabella Dam and within a flood protected area demonstrates that the potential exists for future dam or levee related issues. There are no official recurrence intervals that have been calculated for dam or levee failures. However, based on formal dam and levee monitoring and maintenance protocols in place in Kern County, the probability of future occurrence for both dam and levee failures is Unlikely.

Vulnerability to the Hazard

The CSU Bakersfield campus is subject to the effects of flooding resulting from compromised dams and levees. The Isabella Dam upstream from the campus presents the potential for catastrophic flooding and damage through a majority of the Bakersfield area. The Kern River and extending irrigation channels are lined by levees intended to protect the surrounding areas from rises in water level. In the case of dam failure, the amount of time to respond to the needs of the campus community prior to inundation will be limited to about 8 – 10 hours as indicated in the Extent section above.

The most significant challenge regarding dam failures is they generally result in catastrophic outcomes. The levees that line Kern River and those that encase the irrigation channels are owned and operated by a variety of agencies. Any breach along a
levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

The dam inundation zone covers the majority of Bakersfield and surrounding areas. Everyone downstream of the dam in the inundation zone will be vulnerable to the effects of floods and forces of moving water. The CSU Bakersfield campus lies within the Isabella Dam inundation zone. The levee systems providing a threat to Bakersfield exist along the Kern River through the heart of the city and along extending diversion irrigation channels scattered throughout the region.

The CSU Bakersfield campus lies in proximity to levees lining the Kern River. However, the distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of flood insurance will cause extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the CSU Bakersfield campus will vary depending on when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions. Based on estimate replacement costs of facilities and structures on campus, the total replacement costs are $191,391,025.
Vulnerability Assessment Conclusions

Although the occurrence of dam and levee failures have not been historically relevant in Kern County or near the CSU Bakersfield campus, the potential for hazards related to the region’s levees and dams still exist. The presence of earthquake faults in proximity to the Isabella Dam, the county’s largest reservoir, presents a valid danger to the dam structure in the event of an earthquake. The consequences of a dam failure would generate catastrophic results to downstream communities including Bakersfield. The proximity to the Kern River and the levees providing a barrier between the campus and the river further presents a hazard facing the campus. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.
Drought

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
• **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - Bakersfield versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified in Kern county and the city of Bakersfield where CSU-Bakersfield is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.²⁹

**Extent of the Hazard**

According to the CSU system-wide planning committee, drought conditions have been in effect since 2000, with severe drought from 2012 – 2017. Given the historical occurrence of severe drought impacts throughout the state, and that its extent will likely be exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk to the state, impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire CSU system-wide planning area, the extent of the hazard is variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction.

Note: land subsidence has occurred statewide and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels in California have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. These potential effects, though not reported on campus, are applicable to the campus over the long term.

The CSU - Bakersfield campus planning team identifies the extent of the hazard on campus as Low to Medium due to uninterrupted water sources and consistent water conservation efforts. The ranking (qualitatively) corresponds to D0 – D2 on the Extent scale (below), though Kern County has experienced more severe drought conditions for 15 of the past 20 years, including 3 years of D4 levels. As such, the campus planning team recognizes that while historic impacts shaping the extent of drought on campus have been minimal, the potential impacts are tied to trends across larger geographic areas, and, therefore, the committee recognizes that the extent of drought on campus has the potential to increase in the future.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

</tbody>
</table>
History of the Hazard

Historically, drought has been so prevalent in California that its presence is almost continuous. According to the campus committee, drought conditions have been in effect since 2000, with severe drought from 2012 – 2017. According to the US Drought Monitor, Time Series data, Kern County (which surrounds the planning area) has experienced 7 or more periods of drought covering 15 years from 2000-2021.

Figure 4-8: Periods of Drought in Kern County, California, 2000 – 2021

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-

---

drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.\(^{32}\)

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

*Figure 4-9: Periods of Drought in State of California, 2001 – 2021\(^{33}\)*

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and (according to the US Drought Monitor’s Time Series data), on Kern county, the city of Bakersfield and the CSU - Bakersfield campus planning area:

**2012 – 2017** – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state's agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion.\(^{34}\) The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the

---

groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.35

Potential Impacts of the Hazard

Drought impacts statewide are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the CSU - Bakersfield campus planning area is a reduction in water availability for the municipal area tied to the campus. According to the campus committee, water resources have been an historic concern though no official use restrictions have occurred. Other impacts include crop loss and damage to trees and other natural resources. The footprint of CSU Bakersfield to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of any agricultural research crops and/or field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such.36 However, the wildfire hazard is analyzed separately in this plan. (See section on wildfire hazard).

In reviewing the occurrences of drought for Kern County and the city of Bakersfield which surrounds the campus, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012 - 2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - Bakersfield, the broad geographic extent of the impact (including Kern County) makes it likely that tree mortality occurred to some degree on the campus. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the lack of campus-level data, it is useful for the CSU Committee to assess the impact of tree mortality by viewing it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a

risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will try to acquire data in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.37

At present, drought-related damage to campus buildings and infrastructure at CSU - Bakersfield has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - Bakersfield is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Bakersfield. A reduction of electric power generation and water quality deterioration are also potential impact factors.

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence in the state in any given year. Given that CSU - Bakersfield lies within a county with drought conditions in effect for 15 of the past 20 years, it is prudent to extend this likelihood of occurrence to the planning area.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Bakersfield campus.
Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, state and planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2 million acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses.\textsuperscript{39} In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.\textsuperscript{40}

**Vulnerability of Populations**

Drought vulnerabilities for California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the CSU - Bakersfield campus over the long term.

**Property Vulnerability**

The historical and potential impacts of drought on property statewide include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical

\textsuperscript{40} National Oceanic and Atmospheric Administration National Centers for Environmental Information. *State Climate Summaries: California*. Retrieved 05.04.2021 from: https://statesummaries.ncics.org/chapter/ca/
infrastructure and property. These same vulnerabilities apply to the properties of the CSU - Bakersfield campus over the long term.

**Natural Environment Vulnerability**

The core issue shaping drought vulnerabilities throughout California is water supply and demand. On campus, primary vulnerabilities are campus flora and landscaping, and the challenge of grounds maintenance. Campus efforts to mitigate include water conservation and conversion to drought resistant plants. Statewide, several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources. This key effort both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for CSU - Bakersfield’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of Bakersfield and Kern County, and the surrounding region, such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of statewide vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the
drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

Identified Data Limitations

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

Fault Rupture – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

Liquefaction – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

Subsidence - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local

environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

Location of the Hazard

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. Bakersfield is located in the southern end of the San Joaquin Valley along the eastern edge at the base of the Sierra Nevada Mountains. In general, fault systems occur to the west, east, and south of Bakersfield. Throughout the valley the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels. The CSU Bakersfield campus is situated near the southern bank of the Kern River.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 35-40 miles south and west of the CSU Bakersfield campus. In addition to the San Andreas Fault, Kern County is home to additional fault systems with the potential to generate strong ground shaking. The Breckenridge-Kern Canyon Faults traverse along the foothills 15-20 miles east of the CSU Bakersfield campus. The White Wolf Fault extends 45 miles in length pointing towards the northeast 20 miles southeast of the CSU Bakersfield campus. The 150-mile long Garlock Fault extends from the San Andreas to the northeast 40-45 miles southeast of the CSU Bakersfield campus. (See Figure 4-8).
Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale (Table 4-18 below) was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6.
energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.
Although the closest fault lines to the campus remain 20 or more miles away, given that the entire area of Kern County is at risk to seismic activity and has a history of significant earthquakes resulting in damages, the planning committee ranks the extent of the hazard as Moderate.

History of the Hazard

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Kern County also has a long history of earthquake activity. The entire area of Kern County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

Recently, in 2019, a series of earthquakes occurred in Ridgecrest, CA 80 miles to the east of Bakersfield. On July 4, a 6.4 magnitude earthquake struck followed by a 7.1 magnitude earthquake on July 6. Damage and surface ruptures surrounding the epicenter was extensive but shaking intensity in Bakersfield was minor. CSU Bakersfield personnel reported feeling shaking motion but reported no damages.

The July 21, 1952 Kern County Earthquake estimated a Magnitude 7.7 earthquake struck at 4:52 am. The earthquake occurred on the White Wolf Fault in hills east of Bakersfield resulting in numerous surface ruptures. Twelve people were killed in the county and several hundred were injured. The shaking was strong enough to cave in railroad tunnels near Tehachapi, 40 miles east of Bakersfield. Railroad lines were warped, buildings collapsed in Bakersfield, and there was widespread underground utility and pipeline damage. Shaking was felt from Sacramento to San Diego.

The Fort Tejon Earthquake, a Magnitude 7.9 earthquake, struck in 1857 along the San Andreas fault just outside the northwestern corner of Kern County. The earthquake was able to shift the Kern River upstream and run four feet over its banks. Structural damage was limited as the area was sparsely populated at the time. The Fort Tejon Earthquake remains one of the greatest earthquakes ever recorded in the United States producing a surface rupture extending over 220 miles.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the Kern River and the alluvial soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Bakersfield area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply

---

chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Bakersfield could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Bakersfield could result in extensive casualties. expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Bakersfield region limiting immediate assistance that the campus may normally expect.

Local impacts to the CSU Bakersfield campus caused by an earthquake could include:

- Damage to any nearby refineries and petrol-chemical plants
- Damage and secondary fires to industrial buildings to the east of campus
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway system
- Structural damage to bridges over waterways and flood control channels
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to levees
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology.
The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Kern County fault systems surrounding Bakersfield is included in the following table.

Table 4-16: Major Potentially Active Faults in Proximity to CSU-Bakersfield

<table>
<thead>

</tbody>
</table>

Based on the earthquake shaking potential in the Bakersfield area, the proximity to the San Andreas, Garlock, Wheeler Ridge, White Wolf, and the South Sierra Fault Systems, the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of the supply chain. The geographic location of Bakersfield sits at the base of river systems that have deposited sediment from the surrounding mountains. In many cases, these sediment-based soils are loose and expose the potential for liquefaction. A large portion of southern Bakersfield is known to have high underground water tables as close to the surface as five to fifteen feet.

The known fault systems generating the threat to Bakersfield generally surround the city but do not cross into the city (including the CSU Bakersfield campus). However, the proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected.

Elements of the vulnerability to a major earthquake on the CSU Bakersfield campus will vary depending on when the earthquake were to strike. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at

---

their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer. As the CSU Bakersfield campus is in downstream from dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions. Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $191,391,025.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the Bakersfield region and the CSU Bakersfield campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures,
building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU Bakersfield campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding Bakersfield, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Bakersfield region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The campus will likely be required to address critical needs independently early phases of the disaster.

The campus population is additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shock continue. These effects are magnified for populations having specific vulnerabilities or access limitations.
Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Erosion**

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another”.\(^{46}\) Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and immediately recognizable.

Location of the Hazard

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. As such, for the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the CSU-Bakersfield campus with erosion-prone characteristics. No areas under threat of erosion or erosion in process have been identified on campus, although campus leadership may decide to look for such locations in the future if it decides that it is necessary to so do. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area, such as the Kern River, which is adjacent to the campus.

Extent of the Hazard

There is no published scale of severity or extent for this geologic hazard. If conditions are favorable, erosion is likely to occur. Given no historical occurrence of erosion on campus nor any data identifying specific sites on campus at risk, the planning committee ranks the extent of this hazard as **Low**.

History of the Hazard

While erosion has been recorded along the Edison-Breckenridge Road east of Bakersfield, no erosion events have been recorded on the CSU Bakersfield campus.

Potential Impacts of the Hazard

Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the history of occurrence and extent of erosion statewide, the probability of future occurrence in California is high. That said, with regard to the campus, given the lack of historical events or existing conditions favorable to erosion, the probability of future occurrence is Low. However, conditions could emerge in the future which increase the probability, precipitated by climate change, changes in land-use or other factors.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Bakersfield infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. CSU leadership would consider performing an analysis to identify such at-risk buildings, infrastructure, slopes and soil types in the future.

In the wider Bakersfield community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

A study performed by the Kern River Watershed Coalition Authority in 2015 found that the Bakersfield campus is within an area of higher soil erodibility relative to surrounding areas.\(^{47}\) However, current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

Vulnerability Assessment Conclusions

While the ability to predict future erosion on the CSU Bakersfield campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
**Extreme Temperatures (Extreme Heat)**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.48

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.49 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feels” hotter. The combination of temperature and humidity is known as the heat index.50

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.51 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.52

**Location of the Hazard**

Extreme heat events are a non-spatial hazard and may occur throughout the CSU Bakersfield campus.

**Extent of the Hazard**

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the low 80s up to 100 in the City of Bakersfield. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded in Bakersfield was 114° F on June 28, 1976. With more than 40 extreme heat events since 2007, the campus planning committee ranks the extent of this hazard as **Moderate to High**.

---

50 Ibid.
The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 4-12 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

As the heat index rises, so does the potential danger to people and animals. Table 4-22 (following) shows the health hazards associated with extreme heat.

Table 4-17: Health Risks Associated with Heat Index

</tr>
</tbody>
</table>

**History of the Hazard**

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been two excessive heat events in Bakersfield, both occurring within the last two years. More than 40 additional excessive heat events have been recorded in the wider Kern County area since 2007.

**June 10, 2019:** This event occurred during one of the hottest heat waves to ever hit California, with temperatures breaking records across the state and much of the Southwest.

**May 26, 2020:** The month of May ranked as one of the hottest on record for multiple cities in California, with average temperatures ranging approximately 2.5 to 5 degrees above normal.

**Potential Impacts of the Hazard**

CSU Bakersfield may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

---

Probability of Future Occurrence of the Hazard

There have been extreme heat events in Bakersfield and Kern County for the past two years. With 40 or more events since 2007 (2.8 events per year), the planning committee ranks the probability of occurrence as Highly Likely that the hazard will occur annually.

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result. This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

CSU Bakersfield is aware of the potential for extreme heat events. Fall athletic teams may be exposed to extreme heat during summer training, as well as students during the early part of the fall semester. However, the campus takes precautions to remind students to remain hydrated and runs air conditioning in campus buildings. Kern County also sponsors more than a dozen cooling centers throughout the County that are open to the public when the temperature in the San Joaquin and Kern River Valleys is forecast to be 105° or higher; in the desert areas when the temperature is forecast to be 108° or higher; and in Frazier Park when the temperature is forecast to be 95° or higher. Four of these facilities operate in Bakersfield. The risk of power shut-offs affecting air conditioning is not a concern for the campus because the campus runs on the same power grid as Mercy Hospital Southwest Bakersfield.

Therefore, while this is a hazard that the campus may experience with regularity, the campus has ample familiarity with managing the risks and vulnerabilities.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the CSU Bakersfield campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three degrees on average over the last century, with less rainfall. This may lead to stronger heat events, drought, and an increased risk of wildfires.56

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat.

Flood

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and/or adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that becomes hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur. Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.

- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric River**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.
Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.

Figure 4-13: The Science Behind Atmospheric Rivers

---

Location of the Hazard

The Kern River has been identified as the primary flood source for the City of Bakersfield including the CSU Bakersfield campus. The CSU Bakersfield campus sits entirely within a Zone X Special Flood Hazard Area (SFHA) designation on the Flood Insurance Rate Map. The Zone X designated areas are minimal flood threat.

Figure 4-14: Dams and Levees near Bakersfield
Figure 4-15: HAZUS Flood Boundaries and Assets Near CSU-Bakersfield

Kern County is home to a number of river and stream systems, flood control facilities and levee systems throughout the Bakersfield region including the Kern River. The Kern River drains the southern Sierra Nevada Mountains and Isabella Lake into the southern San Joaquin Valley. The Kern River Watershed is fed by snowmelt from the mountains near Mount Whitney and to the south.

The Kern River feeds into Isabella Lake a reservoir created by the Isabella Lake Dam. The dam is a US Army Corps of Engineers dam in the mountains 50 miles east of the CSU Bakersfield campus. The Kern River flows down through the canyons below the dam and through Bakersfield before reaching the campus. There are three diversion dams on the river downstream from Isabella Lake Dam and upstream from the campus. The CSU Bakersfield campus is situated across from Stockdale Highway separating the southern bank of the Kern River from the campus. The distance from the river to the campus boundary is less than 1,500 feet.

Extent of the Hazard

The CSU Bakersfield campus sits entirely within a Zone X Special Flood Hazard Area (SFHA) designation on the Flood Insurance Rate Map. The Zone X designated are areas
are minimal flood threat. The CSU Bakersfield campus lies within a levee (flood-protected) area. Only in the very rare case that the Kern River were flowing at elevated levels beyond the capacity of the designed flood protection, would the CSU Bakersfield campus likely experience significant flood related damages. As such, the campus planning committee ranks the extent of the hazard as **Low**.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 4-18: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised maps in place of Zones VI-30).</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, base flood elevations derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
<tr>
<td>Zone AH</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 -3 feet.</td>

</tbody>
</table>
Flooding in Bakersfield and the broader Kern County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and numerous fatalities. Although no recorded flood events pertain to the campus footprint, the following provides insight into information of past flooding events that are significant to the CSU Bakersfield campus.

Floods occurring from December 17-20, 2010 were caused as a result of a series of low-pressure systems from the Pacific bringing substantial precipitation to California. Heavy rains were experienced throughout the Bakersfield area in addition to the hills and mountains. Rainfall records were broken at weather stations in Bakersfield and further up in elevation. Roadways were flooded, mudslides were reported, and drainage systems were overwhelmed backing up water into developed communities. Over $5 million in damages occurred during this storm event.

The December 29, 2010 to January 2, 2011 Kern County flooding resulted from heavy rains along the east side of the San Joaquin Valley including eastern portions of Bakersfield. The ground became saturated and was unable to absorb additional precipitation. During this period Bakersfield received almost 6 inches of rain while the higher elevations in the Sierra Nevada mountains received over a foot of additional snow. The flooding that occurred resulted in over $14 million in damages.

Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

**Probability of Future Occurrence of the Hazard**

Kern County is determined to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to a 26.8% chance of flooding in any given year. Given that the location of the CSU Bakersfield campus is in Zone X (area of minimal flooding), the planning committee ranks the annual probability of occurrence as **Unlikely**.

**Vulnerability to the Hazard**

The CSU Bakersfield campus is subject to the effects of limited and isolated flooding or ponding resulting from excessive precipitation, snowmelt, river/levee overflow, or a combination of these. The Isabella Dam upstream from the campus presents the potential for catastrophic flooding and damage through a majority of the Bakersfield area. The Kern River and extending irrigation channels surround the campus and have limited storage or volume capacities.

Vulnerability to flooding on the CSU Bakersfield campus will vary depending on when the flood were to occur and the location of people and assets located within any low lying areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

During low probability, severe flood events, some campus buildings and infrastructure in low lying areas might be vulnerable to large-scale flooding if it reaches the university.

---

Campus utilities and communication capabilities could be impacted by flood waters rendering them disabled. A rare flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in low lying residence halls would be particularly vulnerable especially those without access to adequate transportation.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

**Vulnerability Assessment Conclusions**

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. While the degree of campus vulnerability overall is minimal due to its location, low probability, severe flooding on the CSU-Bakersfield campus and surrounding area generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the campus and the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.
Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.

**Hazardous Materials**

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident**

A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident**

A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident**

A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

---

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards** (fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)
- **Health hazards** (carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

### Natural-Technological Incidents (Natechs)

During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

### Location of the Hazard

Hazardous materials and infrastructure such as fuel, chemicals, hazardous waste sites and gas pipelines are located on each campus. At larger scales (beyond the campus planning area) hazardous materials are located throughout Bakersfield and Kern County, and reflect different types, configurations and scales dispersed across these geographic areas.

### Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard. However, for the CSU – Bakersfield planning committee, based on the degree of hazardous materials (identified through mapping), the history of hazmat events on campus, and because the assessment of risk is so complex, it is prudent to rank the extent of the hazard for the CSU – Bakersfield campus as High and

---

to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including more than 495 documented hazardous materials releases due to the Loma Prieta Earthquake alone (this number excludes innumerable leaks in Pacific Gas & Electric’s natural gas distribution system). That said, it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 20th, 2021 already 2096 spill events had occurred. Such events have occurred in all the cities and/or counties where CSU campuses are located.

With regard to hazmat incidents at CSU - Bakersfield, one chemical spill took place in the science lab in 2015 which resulted in evacuation of the building and spill remediation.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin.

66 Source: 2018 California State Hazard Mitigation Plan, Section 9.2.
Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

On the CSU-Bakersfield campus, hazardous chemicals are stored at the south end of campus, while a gas pipeline runs through the north side. The potential impacts of chemicals and toxic gases discussed above also apply to the students, staff and environment on campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak⁶⁸, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health.⁶⁹ Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. Any CSU campus with a science lab (such as CSU – Bakersfield) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris

---

removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat release on the CSU – Bakersfield campus can be viewed in two different ways: first, is that the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, CSU – Bakersfield has experienced 1 hazmat event. That said, hazmat occurrences are largely based on human error, and changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely affect future probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the CSU – Bakersfield campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: a gas pipeline runs through the north side of campus; hazardous materials are stored at the south end of campus; the science lab conducts experiments with chemicals (and a chemical spill resulted in the evacuation of the science building).

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, CSU – Bakersfield leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions
It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU - Bakersfield) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Kern County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU - Bakersfield campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU - Bakersfield planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Niño storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within the deposition zone and can result in downstream flooding. Post-fire debris flows often occur during the fall and winter following major

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have

---

occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 4-12 (below). Based on Figure 4-12, the CSU-Bakersfield campus is not located in an area susceptible to landslides.

Figure 4-16: CSU-Bakersfield Landslide Susceptibility

Extent of the Hazard

The City of Bakersfield is susceptible to seismic activity from several faults in the region. A strong earthquake or intense rainfall could trigger slope failures in the Greenhorn Mountain foothills and along the Kern River Canyon and floodplain. As these areas are

primarily used for agriculture and open space, people or structures are not likely to be significantly exposed to the impacts of seismically induced landslides. However, the indirect impacts of landslides in the region may cover a larger geographical extent. Based on the campus’ distance from all landslide susceptibility zones, the planning committee ranks the extent of the hazard on campus as **Low**.

**History of the Hazard**

FEMA has declared nine major disasters involving landslides, mudslides, debris flows, or mud flows in Kern County since 1978. NOAA has recorded forty-three debris flow events in the County since 2003, most of which occurred in the Greenhorn Mountains to the east and the San Emigdio Mountains to the south. However, there have been several historic occurrences proximal to or within Bakersfield city limits. On September 3, 2017, strong thunderstorms produced a debris flow in southern Bakersfield that resulted in $50,000 of damage.

**Potential Impacts of the Hazard**

CSU Bakersfield may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually. Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

**Probability of Future Occurrence of the Hazard**

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is often related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events and fires, landslides may generally occur more often. Historically, landslides have occurred frequently in the mountains surrounding the San Joaquin Valley and therefore are likely to occur in this area in the future. However, given the location of the campus well beyond landslide risk zones, the planning committee ranks the probability of the landslide hazard for the campus as **Unlikely**. That said, based on the occasional

occurrence of landslides to the east, the probability of experiencing secondary effects of a landslide such as loss of power or transportation disruption is **Possible**.

**Vulnerability to the Hazard**

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. That said, the CSU Bakersfield campus’ vulnerability is limited to secondary effects of a landslide such as power outage or transportation disruption.

**Estimate of Potential Losses**

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Bakersfield.

**Vulnerability Assessment Conclusions**

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**

The ability to predict future landslides at the CSU Bakersfield campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.75

**Power Outage**

Description of the Hazard

Bakersfield is a charter city in Kern County, California. It is the county seat and largest city of Kern County, covering about 151 square miles near the southern end of the San Joaquin Valley and the Central Valley region. It is also the home of CSU Bakersfield.

Most aspects of modern life, and almost all aspects of urban life, rely on the availability of reliable utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of these commodities can leave highly populated areas like Bakersfield without basic services, such as electricity or sanitation. These interruptions can be cascading effects from other hazard events, such as windstorms, floods, wildfires and earthquakes, or they can be caused by intentional disruptions of transmission lines.

A power outage event can interrupt day-to-day operations of the CSU Bakersfield campus, like in-person classes, impede, or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center and close restaurants around campus and outside the campus. Additionally, thousands of CSU Bakersfield student residents in on-campus housing would also be affected by a power outage on campus and in the surrounding area. Additionally, a severe outage to the City of Bakersfield or to Kern County would directly affect the campus and the community.

Electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of **intentional** disruptions are:

- **Planned**: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- **Unscheduled**: Some intentional disruptions must be done "on the spot" in response to an emergency.
- **Demand-Side Management**: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- **Load Shedding**: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO). CAISO is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities and is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential Public Safety Power Shutoff (PSPS) event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard

CSU Bakersfield has experienced power outages for various reasons. The university worked with the community’s local electric utility company, Southern California Edison (SCE), to restore energy to the campus for its facilities, assets, resident halls, and classrooms. The following are examples of power outage events experienced over recent years:

- July 21, 2020: 1,255 PG&E customers lost power. The outage is impacting areas of Haggin Oaks and Seven Oaks south and southwest of the Cal State Bakersfield campus.

Power outages affecting Bakersfield and Kern County.
February 14, 2019: Two major power outages affecting Kern County. The outages affected approximately 1,500 residents.

October 10, 2019: Pacific Gas & Electric performed a PSPS for approximately 426,000 homes and businesses as red flag warnings were issued across most of California, including Bakersfield, clearing the way for the state’s largest power company to end a preventive outage aimed at reducing wildfire risk.

September 7, 2020: Bakersfield and other Kern County communities were affected by PSPS affecting thousands of county residents.

Potential Impacts of the Hazard

Instructors, campus residents, staff and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. Over the years, what was once a disaster uncharacteristic to landscape is now occurring outside of historical areas. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Bakersfield) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.
Probability of Future Occurrence of the Hazard

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. The City of Bakersfield and Kern County experience such outages. As such, the probability ranking for the Bakersfield area is Likely. Although the CSU Bakersfield campus has recorded fewer events than the surrounding area, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

Vulnerability to the Hazard

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

Estimate of Potential Losses

The data provided by CSU Bakersfield do not report any value for potential losses due to power outage.

Vulnerability Assessment Conclusions

The primary concern for campus leadership is that a loss of power creates potential hazards to students, faculty, and staff at CSU - Bakersfield. Safety and operations protocols center on the following “direct impact” set of concerns:

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and, to maintain a safe campus environment and visibility during nighttime hours. The vulnerable population (especially students with physical disabilities) may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors, and locks and lights may impede on a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations
CSU Bakersfield did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these gases are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU Bakersfield or Kern County is located within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein two (2) inches or more of ashfall following an eruption is possible. While CSU Bakersfield does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 volcanic eruptions in California. The most recent

volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.\textsuperscript{79}

**Potential Impacts of the Hazard**

The specific impacts of the hazard vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Bakersfield is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed herein. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Bakersfield.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and once deposited, poison drinking water, agricultural crops, and grazing land.

**Probability of Future Occurrence of the Hazard**

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. Considering this low probability and CSU Bakerfield’s location, any future eruption is unlikely to have a severe impact on the campus. As such, the annual probability of future occurrence for the campus is ranked by the committee as **Unlikely.**

---

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Bakersfield, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

CSU Bakersfield is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.
**Wildfire**

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain.\(^8^0\) These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a

---

fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. Bakersfield is located in the southern end of the San Joaquin Valley along the eastern edge at the base of the Sierra Nevada Mountains. In general, areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur to the west, east, and south of Bakersfield. These areas surrounding the valley are topographically diverse, contain heavier vegetative fuels, and often have residential development interspersed. The land in the San Joaquin Valley where the CSU Bakersfield campus is located, is largely agricultural, developed, or open grasslands. The CSU Bakersfield campus is situated near the southern bank of the Kern River.

The CSU Bakersfield campus is located in the western portion of the City of Bakersfield. The area immediately surrounding the campus is predominately developed with residential and commercial land uses. The campus has a number of open fields containing short grasses surrounding the main campus. The campus is additionally immediately across Stockdale Highway from the Kern River and the open grassy fields running along the river. To the west of the campus separated by residential neighborhoods and rangeland are areas classified as Moderate Fire Hazard Severity Zones 12 miles away along the California Aqueduct. To the east of the campus, on the opposite side of central Bakersfield along the foothills to the Sierra Nevada Mountains are areas classified as Moderate Fire Hazard Severity Zones. To the southeast of the campus are areas of the Tehachapi Mountains where High Fire Hazard Severity Zones reside 22 miles away but separated by 13 miles of agricultural lands.
Extent of the Hazard

The area immediately surrounding the CSU Bakersfield campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones, and the campus does not have a history of wildfire activity occurring within proximity to the campus. Although the campus is not surrounded by High Fire Severity Zones, it is surrounded by mountain ranges containing forests with an extensive history of large wildfire development and smoke generation. The campus also contains, within its boundaries, fields composed of light and flashy fuels that could lead to grass fires. However, there is no reported history of grass fires on campus. As a result, the planning committee ranks the extent of the wildfire hazard for the CSU Bakersfield campus as Moderate.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily
understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 4-20: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 4: Very High Danger (VH)</td>
<td>Fires start very easily and spread at a very fast rate</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is</td>
</tr>
<tr>
<td>COLOR CODE: Orange</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

rarely possible after they have been burning more than a few minutes.

<table>
<thead>
<tr>
<th>CLASS 5: Extreme (E)</th>
<th>Fire situation is explosive and can result in extensive property damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Red</td>
<td>Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</td>
</tr>
</tbody>
</table>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.

Table 4-21: Air Quality Index for Ozone and Particulate Pollution

History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Kern County also has a long history of wildfire activity primarily in the foothills and mountains surrounding the southern San Joaquin Valley. Wildfires occurring in Kern County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damages.

The area immediately surrounding the CSU Bakersfield campus is not in proximity to high fire hazard zones. Though no wildfires have reached the campus footprint, Kern County contains and is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. As a result, the CSU Bakersfield campus has experienced multiple days of poor air quality due to fires burning in Kern County and neighboring counties. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Bakersfield. CSU Bakersfield personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

The September 4, 2006 Day Fire in northern Ventura County and southern Kern County burned a total of 167,000 acres mostly in Ventura County. The fire demonstrated extreme fire behavior during red flag fire warning conditions. The communities of Pinion Pines, Lake of the Woods, and Pine Mountain were threatened and evacuated. The fire was moving rapidly towards the direction of Kern County. The fire ultimately caused $78 million in damages.

The 2008 Piute Fire burned over 37,000 acres of land in the Walker Basin and Lake Isabella area of Kern County. The fire burned over 45 structures including homes and businesses. The final cost of the fire was $25 million in damages. Severe thunderstorms combined with the destruction of stabilizing vegetation following the fire resulted in flash flooding in the watershed areas near Lake Isabella.

The Erskine Fire ignited on June 23, 2016 in the Lake Isabella area of Kern County consuming 47,864 acres of land and resulted in two fatalities. The fast-moving fire destroyed over 250 homes, another 100 structures, damaged Kern River watershed lands. The fire remains as one the most destructive fires in state history and generated $19.3 million in damages.

Potential Impacts of the Hazard

The location of the CSU Bakersfield campus surrounded by residential and commercial development removed from fire hazard areas places a minimal direct threat from wildfire to the campus. There is potential for grass fires to occur in the surrounding fields.
composed of light and flashy fuels that are within the campus boundaries. The threat of these fields on campus structures is minimal.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts to the campus resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Bakersfield including the campus may be damaged resulting in power outages. Fire-related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic
value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

Based on the wildfire threat potential in the area surrounding the CSU Bakersfield campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered **Unlikely**.

Based on the wildfire threat potential in the area surrounding the Bakersfield region, including the volume of areas in elevated Fire Hazard Severity Zones surrounding the San Joaquin Valley, the probability of wildfire generated smoke impacts to air quality is considered **Possible**.

Vulnerability to the Hazard

The CSU Bakersfield campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban/suburban area of Bakersfield. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of the Bakersfield core and within the agricultural areas surrounding the city. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people or the generation of smoke. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

The greater concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The past few summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the San Joaquin Valley even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Bakersfield students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.
Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU Bakersfield campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The risk to wildfire directly impacting the campus is minimal. Costs would be likely be limited to mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community. No wildfire hazard potential loss estimates for CSU Bakersfield are currently available.

**Vulnerability Assessment Conclusions**

While the occurrence of wildfires has been more frequent in Kern County, historically there have not been wildfire incidents that cause damages near the CSU Bakersfield campus. The location of the CSU Bakersfield campus surrounded by residential and commercial developed neighborhoods limits the ability for wildfire to threaten the campus. The foothills and mountains surrounding the southern San Joaquin Valley host environments that are ideal for the development of wildfire activity. The consequences of fires in these areas would present primary and secondary consequences to the CSU Bakersfield campus and expose vulnerabilities on the campus and to the campus community.

The topography of the valley surrounded by mountains allows for smoke filled air to linger in the Bakersfield area with the potential for unhealthy air quality. Fires in the watersheds of the Kern River and tributaries may damage vegetation stabilizing hillsides.
and result in increased sediments to be discharged into the river system and reservoirs reducing their capacity and effectiveness. Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Data limitations include missing campus structural replacement costs, and lack of both a complete inventory of building construction types and mitigation efforts to lessen the impact due to fire activity. HAZUS generated analysis is focused on the broader community level versus fine-tuning the analysis to the micro-level for facilities such as a university campus.

*Severe Weather (Wind, Tornado, Hail, and Lightning)*

**Description of the Hazard**

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding.85 According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”86

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany

---

severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU Bakersfield.

**Regional Climate Influences on Severe Weather across California**

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High

---

89 Retrieved on 07.17.2021 from [https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-a-frequently-asked-questions](https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-a-frequently-asked-questions)
90 Retrieved on 07.16.2021 from [https://www.pmel.noaa.gov/elnino/what-is-el-nino](https://www.pmel.noaa.gov/elnino/what-is-el-nino)
decreases in intensity and moves south, permitting powerful Pacific storms to move into
and across the state; these storms can produce extreme winds, heavy rains (including
“atmospheric river” events), and widespread coastal and inland flooding. (Please see the
Flood Hazard profile in this document for information on Floods.) As a result, storm
events accompanied by precipitation in California are far more frequent in the winter
months than they are in the summer months.92

While the Mediterranean climate pattern influences the seasonal frequency, intensity,
geographic spread, and type of some severe weather events CSU campuses experience
(including CSU Bakersfield), other severe weather phenomena may occur in California at
any time of the year. For example, near the coast and over the Central Valley, there
appears to be no defined seasonality to thunderstorms, and these storms are usually light
and infrequent. Thunderstorms are more intense and more frequent in the intermediate
and higher elevations of the Sierra Nevada, and occur with greater frequency during the
summer months.93

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent
atmospheric disturbance occurring over land and/or water that is distinguished by its
strength, characteristics, and the scale of the resulting damage.94 The SHMP also lists the
following types of storms that produce hazardous conditions and potential damage
throughout the state of California.95 These storms affect (in varying degrees) all CSU
campuses, including CSU Bakersfield.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms
can produce some of nature’s most destructive and deadly weather including
tornadoes, hail, strong winds, lightning and flooding.96 Thunderstorms are caused
by an atmospheric imbalance from warm unstable air rising rapidly into the
atmosphere. Lightning, which occurs during all thunderstorms, can strike
anywhere.97 Thunderstorms can produce some of nature’s most destructive and
deadly weather including tornadoes, hail, strong winds, lightning and flooding.98

*Severe thunderstorms* are more intense, violent, and dangerous thunderstorms.
The National Oceanic and Atmospheric Administration (NOAA) defines a severe

---

92 Retrieved on 07.17.2021 from [https://wrcc.dri.edu/Climate/narrative_ca.php](https://wrcc.dri.edu/Climate/narrative_ca.php)
93 Retrieved on 07.17.2021 from [https://wrcc.dri.edu/Climate/narrative_ca.php](https://wrcc.dri.edu/Climate/narrative_ca.php)
Thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.  

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.

- **Wind storm**: marked by high wind with little or no precipitation.

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

99 Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
100 Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.\(^{107}\) Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” \(^{108}\)

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU Bakersfield).

**High Winds, Strong Winds, and Thunderstorm Winds**

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

**High Winds**

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\(^{109}\)

**Strong Winds**

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\(^{110}\)

**Thunderstorm Winds**

---

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\footnote{NWS Directive 10-1605, July 16, 2018. Retrieved on 07.15.2021 from https://www.nws.noaa.gov/directives/sym/pd01016005curr.pdf}

Please note: \textit{Straight-line wind} is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\footnote{Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/} However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

\textbf{Tornadoes}

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\footnote{Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/} This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\footnote{Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\footnote{Bytnerowicz, Andrzej, Fenn, Mark, Allen, Edith B. and Cisneros, Ricardo. "SEVEN. Atmospheric Chemistry". Ecosystems of California, edited by Harold Mooney and Erika Zavaleta, Berkeley: University of California Press, 2016, pp. 107-128. https://doi.org/10.1525/9780520962170-011. Retrieved on 07.16.2021 from https://www.fs.fed.us/psw/publications/bytnerowicz/psw_2016_bytnerowicz001.pdf}

\textbf{Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.}

\textbf{Santa Ana Winds}. A type of wind hazard that is peculiar to Southern California is called a \textit{Santa Ana Wind}. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\footnote{Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at
which they can spread a flame across the landscape.¹¹⁷ (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.119

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and
coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour or higher, and can even reach hurricane force (≥74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.\(^{120}\)\(^{121}\)\(^{122}\)

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.\(^ {123}\) It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.\(^ {124}\)

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.\(^ {125}\)

---

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\footnote{National Weather Service. Retrieved on 07.14.2021 from: \url{http://w1.weather.gov/glossary/index.php?letter=l}} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including either at the CSU Bakersfield main campus or at satellite campus facilities owned by the school. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all CSU Bakersfield campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU Bakersfield campuses reflect those of the surrounding community and County. As a result, all assets and people at CSU Bakersfield campuses are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Bakersfield (Kern County) and Lancaster (Los Angeles County) areas, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.\footnote{Retrieved on 07.15.2021 from \url{https://www.rmets.org/resource/beaufort-scale}} First developed in 1805, it is still used today to estimate wind strengths.\footnote{Retrieved on 07.15.2021 from \url{https://www.weather.gov/mfl/beaufort}}

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.
**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{130}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the *date* that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 4-24: Fujita Tornado Scale (Pre-February 2007)\(^{131}\)

Missiles, such as cars and refrigerators would do serious secondary damage that could not be directly identified as F6 damage. If this level is ever achieved, evidence for it might only be found in some manner of ground swirl pattern, for it may never be identifiable through engineering studies.</td>
<td></td>
</tr>
</tbody>
</table>

Table below illustrates the Enhanced Fujita (EF) Scale, currently in use. Tornadoes that have occurred since February, 2007 are classified using the Enhanced Fujita Scale.
Table 4-25: Enhanced Fujita Scale (February 2007 and Later)\textsuperscript{132}

<table>
<thead>
<tr>
<th>Enhanced Fujita Category</th>
<th>Wind Speed</th>
<th>Potential Damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>EF0</td>
<td>65-85 mph</td>
<td>Light damage. Peels surface off some roofs; some damage to gutters or siding; branches broken off trees; shallow-rooted trees pushed over.</td>
</tr>
<tr>
<td>EF1</td>
<td>86-110 mph</td>
<td>Moderate damage. Roofs severely stripped; mobile homes overturned or badly damaged; loss of exterior doors; windows and other glass broken.</td>
</tr>
<tr>
<td>EF2</td>
<td>111-135 mph</td>
<td>Considerable damage. Roofs torn off well-constructed houses; foundations of frame homes shifted; mobile homes completely destroyed; large trees snapped or uprooted; light-object missiles generated; cars lifted off ground.</td>
</tr>
<tr>
<td>EF3</td>
<td>136-165 mph</td>
<td>Severe damage. Entire stories of well-constructed houses destroyed; severe damage to large buildings such as shopping malls; trains overturned; trees debarked; heavy cars lifted off the ground and thrown; structures with weak foundations blown away some distance.</td>
</tr>
<tr>
<td>EF4</td>
<td>166-200 mph</td>
<td>Devastating damage. Well-constructed houses and whole frame houses completely leveled; cars thrown and small missiles generated.</td>
</tr>
<tr>
<td>EF5</td>
<td>&gt;200 mph</td>
<td>Incredible damage. Strong frame houses leveled off foundations and swept away; automobile-sized missiles fly through the air in excess of 100 m (107 yd); high-rise buildings have significant structural deformation; incredible phenomena will occur.</td>
</tr>
</tbody>
</table>

Based on the extent ranking factors identified (above), the planning committee ranks the extent of tornados as **LOW**.

**Extent: Hail**

The National Oceanic and Atmospheric Administration and the Tornado and Storm Research Organization (TORRO) have combined efforts to create the Hailstorm Intensity Scale. Table below provides details of this scale.

Table 4-26: Combined NOAA/TORRO Hailstorm Intensity Scale

<table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the hail hazard as **LOW**.
Extent: Lightning

The National Weather Service (NWS) uses a Lightning Activity Level (LAL) scale to indicate the frequency and character of cloud-to-ground (C/G) lightning. The scale uses a range of 1 – 6, with 6 being the high end of the scale. Table below provides details of the LAL scale.

Table 4-27: Lightning Activity Level (LAL) Scale

</tbody>
</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightening hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms. That said, according to the Glossary of Meteorology published by the American Meteorological Society (AMS), a thunderstorm is reported as light, medium, or heavy according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;
- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;
- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

**History of the Hazard**

Severe weather hazards have been an annual occurrence in Kern County and Los Angeles County, and on both the CSU Bakersfield main campus in Bakersfield (Kern County) and

---

135 Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
136 Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
the satellite campus in Lancaster (Los Angeles County). Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\(^\text{142}\) For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\(^\text{143}\) To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**Kern County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Kern County since 1996.\(^\text{144}\) Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\(^\text{145}\)

- **High Wind:** at least 894 events, or approximately 35.29 events per year
- **Strong Wind:** at least 429 events, or 16.93 events per year
- **Thunderstorm Wind:** at least 54 events, or approximately 2.13 events per year

---

- **All Wind Hazard events** (excluding Tornadoes): at least 1,375 events, or approximately 54.27 events per year\(^{146}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Kern County, there have been at least 1,375 wind hazard events since 1996, excluding tornadoes. That translates to an approximate average historical frequency of occurrence of 54.28 wind hazard events per year.

Please note: Differences between the sums of individual component wind hazard event Database searches (i.e., 1,377 events) and simultaneous Database searches of all wind hazard events (i.e., 1,375 events) are due to multiple event types in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado").\(^{147}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 1,375 events) is used to determine the historical frequency of occurrence for the severe weather hazard.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 1,377 events) and simultaneous Database searches of all severe weather hazard events (i.e., 1,375 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;“ and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” reported for Kern County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{148}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 1,377 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Kern County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Kern County has experienced since 1996 have been costly. There have been 4 deaths and 12 injuries, and property and crop damage estimates have totaled approximately $15,970,000 and $597,500, respectively.

**Tornado Wind Hazards**

---

\(^{146}\) National Climatic Data Center. Storm Events Database. Retrieved on 07.28.2021 from [https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&eventType=%28Z%29+Strong+Wind&eventType=%28C%29+Thunderstorm+Wind&beginDate_mm=04&beginDate_dd=09&beginDate_yyyy=2019&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=KERN%3A29&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA

Information from the NCEI Storm Events Database indicates that since 1996, there have been 10 reported events of tornadoes in Kern County, which translates to approximately 0.39 tornado events per year. All tornado reports in Kern County since 1996 have been of tornadoes with a severity rating of F0/EF0.

**Historical Tornado Hazard Losses for Kern County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Kern County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damages reported, property damage estimates have totaled approximately $189,000.

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 35 reported events of hail in Kern County, which translates to approximately 1.38 hail events per year. (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 36 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, well over 200 miles away from Kern County. The origin of this discrepancy is unknown at this time.)

**Historical Hail Hazard Losses for Kern County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Kern County has experienced since 1996 have been moderate. There have been no deaths, injuries, or crop damages reported, and property damage estimates have totaled approximately $35,000.149 (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Kern County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 40 reported events of lightning in Kern County, which translates to approximately 1.58 lightning events per year.150

**Historical Lightning Hazard Losses for Kern County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Kern County has experienced since 1996 have been costly. There has been 1 death and 4 injuries reported due to lightning, and property damage estimates have totaled approximately $355,000; no crop damage estimates have been reported.

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database (Kern County)**

Information obtained from the NCEI Storm Events Database indicates that there have been 1,460 occurrences of the severe weather hazards in Kern County. This translates to 57.63 severe weather hazard occurrences per year. 151

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 1463 events) and simultaneous Database searches of all severe weather hazard events (i.e., 1460 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;” and/or (2) severe weather hazard events such as “Thunderstorm Wind” “Hail” that have been reported for Kern County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County. 152

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 1460 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Kern County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Kern County has experienced since 1996 have been costly. There have been 5 deaths and 21 injuries, and property and crop damage estimates have totaled approximately $16,549,000 and $597,500, respectively. However, it is important to note that for all Kern County severe weather hazard events recorded on the Storm Events Database, almost all deaths, the majority of injuries, all estimated crop damages, and approximately 96.5% of all estimated property damages have been caused by wind hazard events alone.

**Los Angeles County**

153 National Climatic Data Center. Storm Events Database. Retrieved on 07.28.2021 from
Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Los Angeles County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind**: at least 387 events, or approximately 15.28 events per year
- **Strong Wind**: at least 3 events, or 0.12 events per year
- **Thunderstorm Wind**: at least 43 events, or approximately 1.70 events per year
- **All Wind Hazard events** (excluding Tornadoes): at least 427 events, or approximately 16.86 events per year. (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Los Angeles County, there have been at least 427 wind hazard events since 1996, excluding tornadoes. That translates to an approximate average historical frequency of occurrence of 16.86 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 433 events) and simultaneous Database searches of all severe weather hazard events (i.e., 427 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., ”Thunderstorm Wind/Hail” or ”Hail/Tornado,” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Los Angeles County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 427 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Los Angeles County has experienced since 1996 have been costly. There have been 2 deaths and 4

---

156 National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from [https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+High+Wind&eventType=%28Z%29+Strong+Wind&eventType=%28C%29+Thunderstorm+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=LOS%2BANGELES%3A37&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA

injuries reported from wind hazard events (excluding tornadoes) in Los Angeles County; no property or crop damage has been reported.

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 12 reported events of tornadoes in Los Angeles County, which translates to approximately 0.47 tornado events per year.

The vast majority of tornado reports in Los Angeles County since 1996 have been of tornadoes with a severity rating of F0/EF0. Only one (1) or 12 of the tornadoes reported in has been rated F1/EF1 or higher (it was an F1 tornado that occurred in 1998); that translates to approximately 0.04 events of F1/EF1 tornadoes have occurred per year in Los Angeles County.

**Historical Tornado Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Los Angeles County has experienced since 1996 have been minimal. There have been no deaths, or property or crop damage reported; however, 1 injury has been reported.(Note: An F1/EF1 tornado that occurred in Los Angeles County in 1998 was responsible for the one (1) reported injury.)

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 18 reported events of hail in Los Angeles County, which translates to approximately 0.71 hail events per year. (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of 19 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, over 100 miles away from Los Angeles County. The origin of this error is unknown at this time.)

**Historical Hail Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Los Angeles County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damages reported, there have been property damage estimates that have totaled approximately $3,500,000; the property damage estimate reflects one (1) hail hazard event that occurred in 2003. (Note: The San Diego County hail event that was

miles away, but are erroneously recorded as events that have occurred in the County.\textsuperscript{163} When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 466 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Los Angeles County has experienced since 1996 have been costly. There have been 4 deaths and 18 injuries, and property damage estimates have totaled approximately $3,500,000; no crop damage has been reported. \textit{It is important to note that for all Los Angeles County severe weather hazard events recorded on the Storm Events Database, lightning has accounted for half of the deaths, and for 13 out of 14 (92.9\%) injuries reported. However, hail has accounted for all reported estimated property damages.}

**Wind Hazards Not Included in the NCEI Storm Events Database**

*Santa Ana Winds*

Santa Ana wind events occur at least twice per month from October through April.\textsuperscript{164} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textit{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6 days accounting for 90\% of all occurrences. The remaining 10\% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{165} \textsuperscript{166}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

\begin{itemize}
\item \textsuperscript{165} Retrieved on 07.14.2021 from \url{https://agupubs.onlinelibrary.wiley.com/doi/epdf/10.1002/2016GL067887}
\end{itemize}
Diablo Winds

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\textsuperscript{169}
Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\textsuperscript{170}

Figure 4-20: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\textsuperscript{171}

\textbf{Sundowner Winds}

Strong sundowner wind events occur approximately \textbf{2-3 times per year}. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\textsuperscript{172}

\textbf{Historical Frequency of All Severe Weather Hazards}

The following tables show the average historical frequency of severe weather hazard events for Kern County and Los Angeles County, respectively, since 1996.

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within CSU Bakersfield campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU Bakersfield campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.
Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

**CSU Bakersfield Main Campus, Bakersfield (Kern County)**

According to the 2020 Kern County Multi-Jurisdictional Hazard Mitigation Plan, “high winds/straight-line winds” are considered to be a high-priority severe weather hazard by Kern County. These wind hazards are included in an “Extreme Weather” category, and are rated as having “limited” or low to moderate potential impact on Kern County and (by extension) on the CSU Bakersfield main campus. Tornadoes are not considered to be significant in Kern County; as a result, tornadoes have low significance and minimal potential impact on Kern County and (by extension) on the CSU Bakersfield main campus.

**CSU Bakersfield – Antelope Valley Campus, Lancaster (Los Angeles County)**

According to the 2019 City of Lancaster Hazard Mitigation Plan, “windstorms” are considered to be significant, and are rated as having a moderate to high potential impact on the City of Lancaster and (by extension) on the CSU Bakersfield – Antelope Valley Campus.

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

**CSU Bakersfield Main Campus, Bakersfield (Kern County)**

According to the 2020 Kern County Multi-Jurisdictional Hazard Mitigation Plan, hail hazards are rare in Kern County; as a result, they are considered to be of low significance, and therefore to have a minimal potential impact on Kern County and (by extension) on the CSU Bakersfield main campus.

---

The 2019 City of Lancaster Hazard Mitigation Plan does not consider hail hazards to be significant enough to profile. As a result, hail hazards are considered to be of low significance, and therefore to have a minimal potential impact on the City of Lancaster and (by extension) on the CSU Bakersfield – Antelope Valley Campus.177

**Lightning**

Lightning strikes the United States about 20-25 million times a year.178 Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.179 Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.180 (Commercial claim payouts for lightning losses for the U.S. were not available.)

**CSU Bakersfield Main Campus, Bakersfield (Kern County)**

According to the 2020 Kern County Multi-Jurisdictional Hazard Mitigation Plan, lightning is not identified as a priority hazard; as a result, it is considered to be of low significance, and therefore to have a minimal potential impact on Kern County and (by extension) the CSU Bakersfield main campus.181

The 2019 City of Lancaster Hazard Mitigation Plan does not consider lightning hazards to be significant enough to profile. As a result, lightning hazards are considered to be of low significance, and therefore to have a minimal potential impact on the City of Lancaster and (by extension) on the CSU Bakersfield – Antelope Valley Campus.182

---

Probability of Future Occurrence of the Hazard

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year. Future occurrences of such events are projected to increase in both their frequency and intensity.

**CSU Bakersfield Main Campus, Bakersfield (Kern County)**

The 2020 Kern County Multi-Jurisdictional Hazard Mitigation Plan states that there is between a 10% and 100% chance that severe weather wind hazards profiled will occur in the future in Kern County, and it rates the probability of future occurrence of severe weather (or “extreme weather”) as “likely.” However, according to the NCEI Storm Events Database, severe weather wind hazard events have occurred in Kern County far more than once annually – at an average of 54.28 events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of both CSU Bakersfield main campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU Bakersfield main campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2020 Kern County Multi-Jurisdictional Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) Kern County and the CSU Bakersfield campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for the CSU Bakersfield main campus is **HIGHLY LIKELY**.

**CSU Bakersfield – Antelope Valley Campus, Lancaster (Los Angeles County)**

The 2019 City of Lancaster Hazard Mitigation Plan states that the probability of future severe wind events is approximately 3.08 out of a maximum score of 4.00, where a “3” is considered to be “likely.” However, according to the NCEI Storm Events Database, severe weather wind hazard events have occurred in Los Angeles County far more than once per year – at an average of 16.86 events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Bakersfield – Antelope Valley campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that

the severe weather probabilities for the CSU Bakersfield – Antelope Valley campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2019 City of Lancaster Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU Bakersfield – Antelope Valley campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU Bakersfield – Antelope Valley is **HIGHLY LIKELY**.

**CSU Bakersfield – All Campus Areas**

The probability of future occurrence of the severe weather hazard for all CSU Bakersfield campus areas is **HIGHLY LIKELY**.

The following tables show the probabilities of future occurrence for component severe weather hazards for CSU Bakersfield campuses in Kern County and Los Angeles County.

Table 4-30: Severe Weather Hazard Probabilities of Future Occurrence for Kern County and CSU Bakersfield Main Campus (Bakersfield, CA)

Vulnerability to the Hazard

People, structures, and assets on both CSU Bakersfield campuses are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. Both CSU Bakersfield campuses also have vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire CSU Bakersfield campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.
All structures within all CSU Bakersfield campus areas are at risk from severe weather. Buildings on the main campus could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $191,391,025 for the CSU Bakersfield main campus, and are unknown for the CSU Bakersfield - Antelope Valley campus. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at the CSU Bakersfield campus varies throughout the day. As of Fall, 2019, CSU Bakersfield had 11,199 students and 1,277 faculty and staff. All are at risk from severe weather events, with 12,476 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to both CSU Bakersfield campuses. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU Bakersfield.

It is evident that CSU Bakersfield has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection

---

services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.

4.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in at the end of this section of the HVRA. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Channel Islands campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.
Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”

Table 4-32: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
</table>
| Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning? | - Populations with access and functional needs  
- Non-English-speaking students and employees  
- Populations with mental health issues |
| Which population groups are most difficult to reach in an event?          | N/A                                                  |
| Which population groups have little/limited support networks if impacted by an event? | N/A                                                  |

Note: CSU Bakersfield was early interview, so interview process and question structure were not yet fully defined.

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:
Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**

- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Representatives in the Emergency Operations Center represent immigrant populations. Emergency management leads go and meet with immigrant populations every semester to discuss emergency management issues.
- In addition to the food pantry with a twice a month food distribution, the students have an edible garden.
Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

</table>
**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\(^{187}\) Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\(^ {188}\) Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread

housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.\textsuperscript{189}

\textit{Extreme Temps}

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

\textbf{Heat}

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 190

**Flood**

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such

---

as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion.  

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural health and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, sadness and grief. Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

---

Hazardous Materials

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply
- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease.\(^{193}\) Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.\(^{194}\)

Power Outage/Public Safety Power Shutdowns (PSPS)

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

\(^{193}\) https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/

Wildfire

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. 195 Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old. 196

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: 197 particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs. 198

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy. 199

Hazard Mitigation and Emergency Management Planning

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

5.1 University Profile

University History

California State University Channel Islands (CSU Channel Islands, or CSUCI) is a four-year, public university located in Camarillo (Ventura County), California, and is the newest campus of the California State University (CSU) System. Planning for the establishment of CSU Channel Islands first began in 1965, when State Senator Robert J. Lagomarsino co-authored Senate Bill 288 with Assemblyman Burt Hansen, calling for establishment of a four-year college in Ventura County; that same year, Governor Pat Brown signed a bill authorizing $20,000 for an advance acquisition site study for a state college for Ventura County. However, it was not until 1997 that the California State Legislature and the California State University (CSU) Board of Trustees provided funds to begin the conversion of the Camarillo State Hospital property (located in Camarillo, CA) into a college campus. In August, 1999, the CSU Northridge Ventura Campus moved to the Camarillo, CA site as a satellite facility for CSU Northridge; the site then became known as CSU Northridge at Channel Islands. Three years later, on August 16, 2002, CSU Channel Islands officially opened as the 23rd (and newest) campus in the California State University system. CSU Channel Islands became a federally-recognized Hispanic Serving Institution (HSI) in 2010, and maintains that designation today.

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The President’s Executive Leadership Team addresses the strategic and operational issues of the university. This team provides recommendations on university-wide policies and practices, and advises the campus President on the development and implementation of university strategies and plans.

University Mission

“Placing students at the center of the educational experience, California State University Channel Islands provides undergraduate and graduate education that facilitates learning within and across disciplines through integrative approaches, emphasizes experiential and service learning, and graduates students with multicultural and international perspectives.”
University Location

The CSU Channel Islands main campus is located in Camarillo, California, midway between Santa Barbara and Los Angeles. Aside from the main campus, CSU Channel Islands operates several other facilities in Southern California: (1) a satellite campus in Goleta, CA; (2) a boating center in Oxnard, CA; and (3) the Santa Rosa Island Research Station (SRIRS), a research facility for students and researchers located in Channel Islands National Park, about 26 miles off the coast of Santa Barbara, California.

University Population

CSU Channel Islands has a total enrollment of 7,455 students. The full-time enrollment at is 6,037 students and the part-time enrollment is 1,418. This means that 81% of students enrolled at CSU Channel Islands are enrolled full-time.

The enrolled student population at CSU Channel Islands, both undergraduate and graduate, is 48.6% Hispanic or Latino, 29.2% White, 5.62% Asian, 4.55% Two or More Races, 2.36% Black or African American, 0.349% American Indian or Alaska Native, and 0.121% Native Hawaiian or Other Pacific Islanders.

The most popular Bachelor’s Degree concentrations at CSU Channel Islands were General Psychology, General Business Administration & Management, and Speech Communication & Rhetoric. CSU Channel Islands is a commuter campus.

5.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii)(A): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.
Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate.

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

5.3 Hazard Identification and Risk Assessment

Overview of California State University, Channel Islands History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered 14 hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 5-1 (following).

Table 5-1: Hazard Identification Determinations
## Future Occurrence Probability

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely** - 76%-100% that the hazard would occur annually.
- **Likely** - 50%-75% that the hazard would occur annually.
- **Possible** - 11%-49% that the hazard would occur each annually.
- **Unlikely** - 0%-10% that the hazard would occur each annually.

**Communicable Disease**

**Description of the Hazard**

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague)

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 5-2 below.)

Descriptions of Identified Communicable Disease Hazards at CSU Channel Islands

CSU Channel Islands (CSUCI) has identified two (2) communicable disease hazards that have had the greatest impact on campus – COVID-19 and Measles. The following are brief descriptions of the communicable disease hazards at CSUCI.

COVID-19 (SARS-CoV-2)

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.
The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It’s not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.⁵

Measles

Measles (also known as rubeola) is a highly contagious childhood infection caused by a virus. The measles virus replicates in the nose and throat of an infected child or adult. Then, when someone with measles coughs, sneezes or talks, infected droplets spray into the air, where other people can inhale them. The infected droplets may also land on a surface, where they remain active and contagious for several hours. The virus is contracted by putting touching one’s nose, mouth, or eyes after touching the infected surface.

Measles can be serious and even fatal for small children. The disease still kills more than 100,000 people a year worldwide, most under the age of 5. However, as a result of high vaccination rates in general, measles hasn’t been widespread in the United States for more than a decade.⁶

Location of the Hazard

Communicable diseases have the potential to affect the entire CSU-Channel Islands (CSUCI) planning area equally. As a result, the communicable disease hazard can be found at the CSU Channel Islands (CSUCI) main campus located in Camarillo, CA (Ventura County). The communicable disease hazard can also be found at three (3) facilities that CSUCI operates:

- A satellite campus (CSUCI Extended University) in Goleta, CA (Santa Barbara County);\(^7\)
- A boating center for CSUCI students and local community members (CSU Channel Islands Boating Center) in Oxnard, CA (Ventura County);\(^8\) and
- The Santa Rosa Island Research Station (SRIRS), a research facility for students and researchers located in Channel Islands National Park, about 26 miles off the coast of Santa Barbara, California (Santa Barbara County).\(^9\)

Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) all CSUCI locations are at risk of exposure to the communicable disease hazard.

**CSU Student Housing Locations and Populations**

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. Table 5-4 shows the number of students that were living in CSU-campus-owned housing in Fall 2019, prior to the COVID-19 pandemic.\(^{10,11}\)

</tbody>
</table>

**Extent of the Hazard**

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard.

Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling,

---

laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 5-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

Figure 5-1: Biosafety Levels (BSLs)\(^{15}\)

---

**The Extent of CSU Channel Islands Communicable Disease Hazards Except COVID-19:**

Before the COVID-19 pandemic, there were cases of measles at CSU Channel Islands. Measles would be classified at the BSL-2 containment level.\(^{16}\)

**The Extent of CSU Channel Islands COVID-19 Communicable Disease Hazard:**

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.\(^{17}\)

**History of the Hazard**

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 27 cases of COVID-19 at CSU Channel Islands. CSU-campus-specific COVID-19 case data for CSU Channel Islands can be found in the *History of the Hazard* section below.

---

Most communicable disease data are maintained by the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

The following tables show both campus and County-level COVID-19 Case data for CSUCI. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

The following (Table 5-5) includes confirmed COVID-19 cases since May 2020 involving CSUCI students, faculty or staff who may have exposed others while working, visiting, attending in-person instruction, or living on campus (student housing) during the illness.

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the CSU – Channel Islands campus. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contracts communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU – Channel Islands students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic, and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU – Channel Islands) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).\textsuperscript{21}

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

\textsuperscript{20} Santa Barbara County Public Health Department. Community Data Dashboard. Retrieved 03.18.2021 from: https://publichealthsbc.org/data/

Table 5-8: WHO Risk Group Categorization\textsuperscript{22}

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 5-9 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 5-9: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions\textsuperscript{23}

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>

\textsuperscript{23} CDC/National Institutes of Health. Biosafety in Microbiological and Biomedical Laboratories, 6\textsuperscript{th} Ed. Print. Retrieved 05.03.2021 from: https://www.cdc.gov/labs/BMBL.html
<table>
<thead>
<tr>
<th>Risk Group</th>
<th>Bacteria and Viruses</th>
<th>Precautions</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG 1</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one's hands with anti-bacterial soap, washing all exposed surfaces of the lab with disinfectants, etc.).</td>
</tr>
<tr>
<td>RG 2</td>
<td>Chicken Pox, Hepatitis A, B, C, Lyme disease, Salmonella, Mumps, Measles, Malaria, Scrapie, Dengue Fever, HIV</td>
<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
<tr>
<td>RG 3</td>
<td>Anthrax, West Nile Virus, SARS Virus (Including COVID-19), Tuberculosis, Typhus, Yellow Fever, Hantaviruses, Avian Flu</td>
<td>These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.</td>
</tr>
</tbody>
</table>
These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

Probability of Future Occurrence of the Hazard

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency. Table 5-12 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 5-10: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a
communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Note: Each communicable disease’s probability of future occurrence ranking CSU-system-wide reflects the ranking at the individual CSU campus level unless noted otherwise.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the CSU – Channel Islands campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall
2019, the CSU System had 480,541 students and 53,763 faculty and staff. Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree in the current COVID-19 pandemic on the Channel Islands campus.

Estimate of Potential Losses

The COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU – Channel Islands) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

Economic Impact of COVID-19 Pandemic on CSU Financial Health

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 5-2 below for the economic impact to the CSU – Channel Islands campus). Several CSU campuses saw refund losses surpass $10 million.

24 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 5-15) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems. See Table 5-13 below for the “10% outbreak scenario” projections for the CSU – Channel Islands campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system, including CSU – Channel Islands. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist...
is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Dam and Levee Failure**

**Description of the Hazard**

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

---

Levee failures can vary from over toppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

Ventura County is home to a variety of flood control facilities and levee systems mostly in the coastal plains and valleys region including along the Santa Clara River and Calleguas Creek. The Santa Clara River drains the mountains of Ventura County and Lake Piru and Castaic Lake in Los Angeles County towards Ventura. The Calleguas Creek drains the Santa Monica Mountains and the Conejo Valley passing just northwest of the CSU Channel Islands campus.

The Calleguas Creek is normally a dry creek providing flood control and drainage. The creek feeds into the Pacific Ocean before extending 30 miles from Simi Valley. The Bard Lake reservoir through the Wood Ranch Dam also feeds into the Calleguas Creek just southeast of Simi Valley. The creek is an unregulated channel from the dam to the ocean. The CSU Channel Islands campus is situated slightly higher in elevation on a hillside from the Calleguas Creek channel. The distance from the river to the campus boundary is just over a half of a mile.

Levees have been constructed to protect the banks of the Calleguas Creek as the channel extends past the campus. Levees are also used in containment of flood channels in areas of level topography on the valley floor. The northwest part of the CSU Channel Islands campus is located within a designated levee protected zone identified in the National Levee Database34 affecting Modoc Hall, El Dorado Hall, Central Plant, and University Drive.

---
Figure 5-3: Dams and Levees Located Near CSU Channel Islands
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- High hazard potential dams may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- Significant hazard potential dams are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- Low hazard potential dams are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

<tr>
<td>Calleguas</td>
<td>Wood Ranch</td>
<td>11,000af</td>
<td>High Hazard</td>
</tr>
</tbody>
</table>

The CSU Channel Islands campus lies outside of the inundation zone of the Wood Ranch Dam. In the event of a catastrophic failure of the Wood Ranch Dam, the CSU Channel Islands campus is expected to remain out of the inundation area. The inundation area is expected to spread water on the opposite side of the Calleguas Creek channel. However, there are multiple transportation corridors that lie within the dam inundation zone that would compromise access to and from the campus affecting the ability to evacuate, gain access to emergency services, and receive supplies. The roadways expected to become inundated in a dam breach scenario include South Lewis Road, the primary access route to the campus from US Highway 101 and other Ventura County locations and US Highway 101 is anticipated to be affected in Camarillo. Based on these conditions, the planning committee ranks the extent of the dam failure hazard as Low.
Extent – Levee Failure

Levees are used along numerous irrigation channels and other waterways including the Calleguas Creek. The eastern bank of the Calleguas Creek channel is lined with a levee protecting the area surrounding the campus. A portion of the CSU Channel Islands campus lies within a levee flood protected area. In the event the Calleguas Creek was flowing at elevated levels and a failure of a levee were to occur, the western edges of the CSU Channel Islands campus would likely experience flood related damages. This specific hazard would substantially alter the ability of the campus to maintain operations as damages would be extensive. Depending on the location of a breach, the campus community would be heavily affected with the loss of life and homes, access to campus would be limited, and student financial capacity to support ongoing education being

35 California Department of Water Resources, *Dam Breach Inundation Map Publisher*. Retrieved 04.13.2021 from: [https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2](https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2)
diminished. Based on these conditions, the planning committee ranks the extent of the levee failure hazard as **Moderate**.

**History of the Hazard**

There are no records of dam failure for any dam within Ventura County.

However, in March of 1928, the St. Francis Dam in Los Angeles County providing water storage for the Owens River Aqueduct collapsed shortly after being constructed. The downstream channel fed into the Santa Clara River in Ventura County. The midnight collapse created a wall of water moving down the valley that was reported to be as high as 78 feet tall 42 miles from the collapse. This inundation created 25 feet deep waters throughout the river valley including in the town of Santa Paula. Virtually everything in the path of the rushing water was destroyed including bridges, structures, orchards, and railways. 70-foot-deep mud deposits and massive debris were left behind. It is estimated that 500 people were killed, and damages were $20 million in 1928.

**Potential Impacts of the Hazard**

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris

**Levee Failure Impacts**

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure
may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

**Probability of Future Occurrence of the Hazard**

Ventura County remains at risk from dam and levee failure. The location of the CSU Channel Islands campus downstream from the Bard Lake/Wood Ranch Dam and Lake Piru in addition to being within a flood protected area demonstrates that the potential exists for future dam or levee related issues. There are no official recurrence intervals that have been calculated for dam or levee failures. The probability of future occurrence for both dam and levee failures is **Unlikely**.

**Vulnerability to the Hazard**

The CSU Channel Islands campus is subject to the effects of flooding resulting from compromised dams and levees. The Wood Ranch Dam upstream from the campus presents the potential for catastrophic flooding and damage through much of the Camarillo area. The Calleguas Creek and extending irrigation channels are lined by levees intended to protect the surrounding areas from rises in water level. In the case of dam failure, the amount of time to respond to the needs of the campus community prior to inundation will be limited.

The most significant challenge regarding dam failures is they generally result in catastrophic outcomes. The levees that line Calleguas Creek and those that encase the irrigation channels are owned and operated by a variety of agencies. Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.
The dam inundation zone covers an area 1.5 miles wide in the center of Camarillo and extends downstream towards the CSU Channel Islands campus. Everyone downstream of the dam in the inundation zone will be vulnerable to the effects of floods and forces of moving water. The CSU Channel Islands campus lies just outside the Wood Ranch Dam inundation zone. However, the access routes into campus remain inside the inundation zone.

The levee systems presenting a threat to Camarillo exist along the Calleguas Creek through the heart of the city and extending southward towards the campus. The CSU Channel Islands campus lies in proximity to levees lining the Calleguas Creek. However, the distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in the vulnerability of numerous displaced individuals and households. The lack of flood insurance will cause extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the CSU Channel Islands campus will vary depending on when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $191,391,025. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU Channel Islands.
Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the CSU Channel Islands campus, the potential for hazards related to the region’s levees and dams still exist. However, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences of a dam failure would generate catastrophic results to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.
Drought

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - Channel Islands) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified in Ventura County and the city of Camarillo where CSU – Channel Islands is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000 – 2020, drought conditions have existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.36

**Extent of the Hazard**

Given the historical occurrence of severe drought impacts throughout the planning area and across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire planning equally, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction.

In addition, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels in California have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. These potential effects of drought are rare, but are applicable concerns for the campus over the long term.

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the

---

U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

</tbody>
</table>

Ski and rafting business is low, mountain communities suffer
Orchard removal and well drilling company business increase; panning for gold increases
Low river levels impede fish migration and cause lower survival rates
Wildlife encroach on developed areas; little native food and water is available for bears, which hibernate less
Water sanitation is a concern, reservoir levels drop significantly, surface water is nearly dry, flows are very low; water theft occurs
Wells and aquifer levels decrease; homeowners drill new wells
Water conservation rebate programs increase; water use restrictions are implemented; water transfers increase
Water is inadequate for agriculture, wildlife, and urban needs; reservoirs are extremely low; hydropower is restricted
Fields are left fallow; orchards are removed; vegetable yields are low; honey harvest is small
Fire season is very costly; number of fires and area burned are extensive
Many recreational activities are affected
Fish rescue and relocation begins; pine beetle infestation occurs; forest mortality is high; wetlands dry up; survival of native plants and animals is low; fewer wildflowers bloom; wildlife death is widespread; algae blooms appear
Policy change; agriculture unemployment is high, food aid is needed
Poor air quality affects health; greenhouse gas emissions increase as hydropower production decreases; West Nile Virus outbreaks rise
Water shortages are widespread; surface water is depleted; federal irrigation water deliveries are extremely low; junior water rights are curtailed; water prices are extremely high; wells are dry, more and deeper wells are drilled; water quality is poor;

**History of the Hazard**

Historically, drought has been so prevalent in California that its presence is almost continuous. According to the US Drought Monitor, Time Series data, Ventura County has experienced numerous drought period from 2000–2021 but it has not impacted the CSU-Channel Islands footprint due to consistent water reservoir sources.

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period.
These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

Figure 5-5: Periods of Drought in Ventura County, California, 2000 – 2021

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

---

Given the ubiquitous nature of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and (according to the US Drought Monitor’s Time Series data) on the city, county and region surrounding CSU - Channel Islands campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by the UC Davis Center for Watershed Sciences, the 2012 - 2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal”. The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.

---

Potential Impacts of the Hazard

Though the campus committee reports a low risk of drought owing to reservoir resources, potential drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that although there are no historic occurrences of drought in the planning area, the campus is a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

Though no campus drought impacts have occurred, the most significant potential impact associated with drought across the CSU - Channel Islands campus planning area is the reduction in water availability for the municipal area tied to the campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - Channel Islands to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of agricultural research crops and field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such.43 However, the wildfire hazard is analyzed separately in this plan. (See wildfire hazard).

In reviewing the occurrences of drought for CSU - Channel Islands (in municipality and county), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2014-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - Channel Islands, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids.

Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.\(^{44}\)

At present, drought-related damage to campus buildings and infrastructure at CSU - Channel Islands has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - Channel Islands is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Channel Islands. A reduction of electric power generation and water quality deterioration are also potential impact factors.

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence somewhere in the state in any given year. Given that CSU - Channel Islands lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area even though it currently is considered a low-risk hazard on campus.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Channel Islands campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - Channel Islands planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2-million-acre feet per year, where the impacts of drought include decreased
availability of water for agriculture and environmental uses.\footnote{CAL FIRE Fire and Resource Assessment Program (FRAP). \textit{Water Assessment}. Print. Retrieved 05.04.2021 from: \url{https://frap.fire.ca.gov/data/assessment2010/pdfs/3.1water.pdf}} In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5\% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.\footnote{National Oceanic and Atmospheric Administration National Centers for Environmental Information. \textit{State Climate Summaries: California}. Retrieved 05.04.2021 from: \url{https://statesummaries.ncics.org/chapter/ca/}}

**Vulnerability of Populations**

The historical and potential impacts of drought on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the CSU - Channel Islands campus.

**Property Vulnerability**

The historical and potential impacts of drought on property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the CSU - Channel Islands campus.

**Natural Environment Vulnerability**

The core issue shaping drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.
With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for CSU - Channel Islands’ critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the city and county of Los Angeles, and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result is ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

In addition to ground motion, there are several secondary hazards that can result from an earthquake including:

Fault Rupture – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

Liquefaction – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.
Subsidence - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

Location of the Hazard

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU Channel Islands is located in the Oxnard Plain at the western edge of the Santa Monica Mountains. In general, fault systems surround and traverse through Ventura County including the area of CSU Channel Islands. Throughout the valley the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 50-60 miles northeast of the CSU Channel Islands campus. In addition to the San Andreas Fault, Ventura County is home to or near additional fault systems with the potential to generate strong ground shaking. The Simi-Santa Rosa Fault traverses east to west through Simi Valley into Camarillo 5 miles north of the CSU Channel Islands campus. The Malibu Coast Fault extends approximately east to west 45 miles in length from Santa Monica westward into the Pacific Ocean 7 miles south of the CSU Channel Islands campus. The 30-mile long Oak Ridge Fault extends the length of the Santa Clara River Valley from east of Piru into Ventura 10 miles north of the CSU Channel Islands campus. The Ventura-Pitas Fault parallels the Oak Ridge Fault just to the north through the western portion of the Santa Clara River Valley 12 miles from the campus. The San Cayetano Fault extends in an east to west direction along the base of the mountains of the Western Transverse Range 19 miles north of the campus. There are numerous additional faults in the area.
Figure 5-7A: Faults Located Near CSU Channel Islands

Figure 5-8B: Liquefaction Zone Near CSU Channel Islands
Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.
The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Figure 5-9: Earthquake Magnitude and Equivalent Energy Release

![Figure 5-9: Earthquake Magnitude and Equivalent Energy Release](https://www.usgs.gov/media/images/graph-showing-earthquake-magnitudes-and-equivalent-energy-release)

---

Based on the earthquake shaking potential in the Ventura County area, the campus residing within a liquefaction zone, the proximity to numerous fault systems including the San Andreas, Oakridge, Red Mountain, San Cayetano, Santa Susana, and the Simi-Santa Rosa Fault Systems, the extent of the earthquake risk is considered Moderate.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Ventura County has a limited history of earthquake activity within the County’s boundaries but experienced shaking from earthquakes originating in other counties. The entire area of Ventura County is at risk to seismic activity and has a minimal history of significant earthquakes resulting in damages.

*Damages include combined damages including outside of Ventura County

The February 9, 1971 San Fernando Earthquake estimated a Magnitude 6.5 earthquake struck resulting in significant shaking Ventura County. The earthquake occurred just east of San Fernando, 25 miles to the east of Simi Valley. The earthquake resulted in numerous surface ruptures and significant infrastructure destruction. Significant structural damage occurred throughout the San Fernando Valley area including homes,

---

freeways, businesses, hospitals, and other structural damages. The shaking was strong enough to felt throughout southern California, however damages in Ventura County were moderated.

On February 21, 1973, an earthquake struck the Point Mugu area. The shaking was responsible for over $1 million in damages, injuries, and moderate damages. Damages included landslides onto highways, utilities, structural damages to homes, and underground pipes. This earthquake was centered only a few miles from the CSU Channel Islands campus location.

The San Fernando Valley experienced another major earthquake on January 17, 1994. This earthquake was felt throughout southern California. The shaking was the strongest recorded in an urban setting in North America causing the collapse of buildings, apartments, offices, homes, and roadway infrastructure. The quake caused over 25,000 dwellings to be uninhabitable, over $20 billion in damages (1994 values), and 57 fatalities.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the Oxnard Plain and the alluvial soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Oxnard and Camarillo area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Camarillo could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Camarillo could result in extensive casualties. expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Ventura County region limiting immediate assistance that the campus may normally expect.

Some local CSU Channel Islands campus impacts caused by earthquake could include:

- Landslides blocking access routes such as Potrero Rd, Pacific Coast Highway, and US Highway 101
- Structural damage to bridges accessing campus from South Lewis Road
- Potential isolation of campus from community
- Structural damage to Calleguas Creek levees
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to power plant and potential loss of power and release of hazardous materials
- Considerable stress and fear among community
- Closure or reduction of service to campus operations

**Probability of Future Occurrence of the Hazard**

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Ventura County fault systems surrounding Camarillo is included in the following table.

**Table 5-20: Major Potentially Active Faults in Proximity to CSU Channel Islands**

Based on the earthquake shaking potential in the Ventura County area, the campus residing within a liquefaction zone, the proximity to numerous fault systems including the San Andreas, Oakridge, Red Mountain, San Cayetano, Santa Susana, and the Simi-Santa Rosa Fault Systems, the probability of seismic ground shaking generating damage is considered **Possible**.

---

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of the Channel Islands campus sits at the edge of an alluvial plain that is composed of deposited sediment from the surrounding mountains. In many cases, these sediment-based soils are loose and expose the potential for liquefaction. The majority of the Oxnard Plain has identified a moderate risk of liquefaction including most of the campus.

The known fault systems generating the threat to Ventura County exist on all sides of the area including near the CSU Channel Islands campus. As such, the proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment

Elements of the vulnerability to a major earthquake on the CSU Channel Islands campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the area. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.
There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $179,257,992.

**Vulnerability Assessment Conclusions**

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the Ventura County region and the CSU Channel Islands campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake
exists affecting the campus and causing extensive challenges to the CSU Channel Islands campus and community.

In the event that a major earthquake was to strike along the fault systems surrounding Camarillo, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Ventura County region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shock continue. These effects are magnified for populations having specific vulnerabilities or access limitations.

Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Erosion**

Description of the Hazard

The US Geological Survey (USGS) defines erosion as "the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another."\(^{53}\) Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While coastal erosion can happen in any storm, it is more likely during El Niño events, which occur every 5-7 years. For the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across those areas of the CSU – Channel Islands campus with erosion-prone characteristics. For example, erosion has been found in the hillside areas around canals on campus. No other areas under threat of erosion or erosion in process have been identified, though campus leadership may decide to conduct a campus-wide assessment in the future if it decides such an effort is needed.

Other incidents of erosion, such as occurs around buildings, is relatively non-spatial and can occur in any locations with conducive soil structure and a source of movement, such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover.

Extent of the Hazard

Erosion is occurring on the Pacific coastline west of CSU Channel Islands. While there is no published scale of severity or extent for this geologic hazard on the CSU Channel Islands campus, erosion is likely to occur if conditions are favorable. However, given some historical occurrence of erosion on campus, the planning committee ranks the extent of this hazard as Moderate.

History of the Hazard

CSU Channel Islands has experienced past erosion in the hillside areas around canals. Mitigation projects, including replacing ripraps, are being routinely performed.

---

Potential Impacts of the Hazard

Coastal erosion can result in severe impacts to local infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

Probability of Future Occurrence of the Hazard

Erosion is an on-going and dynamic process that occurs regularly. As climate change raises sea levels and induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. In consideration of the history of occurrence on campus and the potential extent of erosion on and near campus, the probability of at least a limited degree of erosion taking place somewhere on the campus in the future is **High** over the long term.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Channel Islands infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. CSU leadership would consider performing an analysis on specific at-risk buildings, slopes and soil types in the future.

In the wider Camarillo community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks.

Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

Vulnerability Assessment Conclusions

While the ability to predict future erosion on the CSU Channel Islands campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
**Flood**

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and/or adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding may result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.
- **Riverine Flooding** – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the waterway exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

- **Localized Flooding** – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

- **Infrastructure Failure** – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

- **Coastal Flooding** – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

**Atmospheric River**

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Figure 5-10: The Science Behind Atmospheric Rivers

**The science behind atmospheric rivers**

An atmospheric river (AR) is a flowing column of condensed water vapor in the atmosphere responsible for producing significant levels of rain and snow, especially in the Western United States. When ARs move inland and sweep over the mountains, the water vapor rises and cools to create heavy precipitation. Though many ARs are weak systems that simply provide beneficial rain or snow, some of the larger, more powerful ARs can create extreme rainfall and floods capable of disrupting travel, inducing mudslides and causing catastrophic damage to life and property. Visit [www.research.noaa.gov](http://www.research.noaa.gov) to learn more.

---

**Location of the Hazard**

The Ventura River, Santa Clara River, and Calleguas Creek have been identified as the primary flood sources for Ventura County. The CSU Channel Islands campus is located adjacent to the Calleguas Creek channel. The Calleguas Creek channel and its protecting levees separates the campus buildings and facilities from the primary access route into other communities in Ventura County. The main part of the campus is slightly higher in elevation than the creek channel. The library and residential neighborhood are further elevated ascending up the hillside. The majority of the CSU Channel Islands campus sits within a Special Flood Hazard Area (SFHA) Zone X (0.2% of Annual Chance of Flood Hazard) designation on the Flood Insurance Rate Map. The athletic fields, northern parking areas, and the western area including Modoc Hall, El Dorado Hall, and the Central Plant reside in a Zone AE Special Flood Hazard Area (Area Inundated by 1% Annual Chance of Flooding). The Zone A designated areas are subject to inundation by a 1-percent annual chance that a flood event will occur.

---

Figure 5-11: Flood Hazard Areas at CSU Channel Islands
Ventura County is home to a number of river and stream systems, flood control facilities and levee systems throughout the Santa Clara River Valley and Oxnard Plain regions including the Calleguas Creek. The Calleguas Creek drains the northern portions of the Santa Monica Mountains. The Calleguas Creek is normally dry however can drain substantial volumes of water in heavy precipitation events. The creek channel is located just over a half mile from the main parts of the campus.

Extent of the Hazard
The CSU Channel Islands campus is located mostly in a designated Zone X: 0.2% Annual Chance Flood Hazard. Portions of the northern and western edges of the campus are located within a Zone AE: 1% Annual Chance Flood Hazard. The access routes into and out of the campus servicing Ventura County locations are found in areas designated as Zone AE: 1% Annual Chance Flood Hazard. Although comprehensive campus-level flood data is not available, given that 9 Federally declared flood disasters have occurred in/near the city of Camarillo, along with frequent/annual flood events in winter months, the planning committee ranks the extent of the flood hazard on campus as Moderate. Another consideration for the ranking is that the northern and western portions of the CSU Channel Islands campus lies within a levee flood protected area. In the event Calleguas Creek was flowing at elevated levels beyond the capacity of the designed flood protection, the CSU Channel Islands campus would potentially experience significant flood related damages in these protected areas. Based on these factors. The planning committee ranks the extent of the hazard as Moderate.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 5-22: Flood Zone Designations and Descriptions

Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, BFEs derived from detailed analyses are shown at selected intervals within these zones.

Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.

Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.

Represents areas between the limits of the 1% annual chance flooding and 0.2% chance flooding.

Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFEs or depths are shown within this zone.

**History of the Hazard**

Flooding in Camarillo and the broader Ventura County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and numerous fatalities. Although no record of flood events are available, heavy rainfall on campus is known to create isolated flooding and ponding. The following provides insight into information of past flooding events that are significant to the CSU Channel Islands campus.

**Potential Impacts of the Hazard**

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source.

Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

Ventura County is determined to be at high risk from flooding. The repeated historic occurrences have shown that the region is subject to a 20% chance of flooding in any given year.\(^5^6\) The location of the CSU Channel Islands campus within a Special Flood Hazard Area demonstrates that the potential exists for flooding events.

Based on flood history and campus location in the SFHA, the probability of future occurrence for flooding is **Likely**.

Vulnerability to the Hazard

The CSU Channel Islands campus is subject to the effects of flooding resulting from excessive precipitation, snowmelt, river/levee overflow, or a combination of these. The Calleguas Creek channel presents the greatest potential for flooding and damage on campus and surrounding agricultural areas surrounding the campus. The channels and extending irrigation channels that surround the campus have limited storage or volume capacities. The campus and the campus community are vulnerable to the effects generated by flooding from these systems. Runoff from heavy precipitation in the hillsides along the eastern border of the campus presents a potential threat for flash flooding and isolated small floods on campus.

Vulnerability to flooding on the CSU Channel Islands campus will vary depending on when the flood were to occur and the location of any people and assets located in low lying areas and Zone AE areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

Some campus buildings and infrastructure, especially those located in low lying areas and Zone AE areas, could be vulnerable to large-scale flooding if it reaches the university. Campus utilities and communication capabilities could be impacted by flood waters rendering them disabled. A rare flood covering a large portion of the city could likely affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus areas.

buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls, if located in low lying areas and Zone AE areas, may have transportation limitations requiring evacuation procedures to be implemented if populated. Flood waters in such areas may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $179,257,992. However due to one portion of the campus being located in levee protected area, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located mostly in an area of minimal flood potential (Zone X), it also contains Zone AE areas and other low-lying areas. As such, the primary vulnerabilities to flood on campus are people and assets in Zone AE and other low-lying areas exposed to flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. The proximity to the Calleguas Creek in addition to the levees providing a barrier between the campus and the creek channel further presents a hazard facing the campus.

The potential for flooding on the campus and surrounding area generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the campus and the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.
Hazardous Materials

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”57 Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

Fixed Hazardous Materials Incident: A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

Transportation Hazardous Materials Incident: A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

Pipeline Incident: A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health.58 Information provided by California Division of Safety and Health includes guidelines related to:

- Safety hazards: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)

---

- **Health hazards**: carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness

**Natural-Technological Incidents (Natechs)**: During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. Please refer to Annex 7 for the map identifying the types and locations of hazardous materials and infrastructure on or near the CSU – Channel Islands campus. The planning committee indicates no known hazardous materials are present on campus. At larger scales (beyond the campus planning area), a rail line and one hazardous waste site are about one (1) mile from the campus, and hazardous materials and infrastructure are located throughout the city of Camarillo and Ventura County, and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

For the CSU – Channel Islands planning committee, no hazmat events have taken place on campus, and no hazardous materials are located close to the campus. Based on these factors along with the types and levels of hazardous materials in the larger community, the extent of the hazard for the CSU – Channel Islands campus is Low, but to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

---

For example, 400 hazardous materials problems are tied to 32 past earthquakes, including more than 495 documented hazardous materials releases due to the Loma Prieta Earthquake alone (this number excludes innumerable leaks in Pacific Gas & Electric’s natural gas distribution system). That said, it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the California Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 2021, a total of 2,096 spill events had occurred so far this year. Such events have occurred in all the cities and/or counties where CSU campuses are located.

No hazmat incidents have taken place on the CSU – Channel Islands campus.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here to some degree apply to the students, staff and environment on the CSU – Channel Islands campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a

---

long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak\textsuperscript{64}, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health.\textsuperscript{65} Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – East Bay) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

**Probability of Future Occurrence of the Hazard**

The probability of occurrence for a hazmat event on the CSU – Channel Islands campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low because the CSU – Channel Islands campus has no known hazardous materials, and it has not experienced a

That said, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the CSU – Channel Islands campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: no hazardous materials are located on campus, and a rail line and waste facility are about one (1) mile from the campus. Gases and chemicals or hazardous waste, if spilled or released, could severely impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Channel Islands leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – East Bay) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Alameda County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Channel Islands campus, campus-level risks and vulnerabilities are not
discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – Channel Islands planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within its deposition zone, and can result in downstream flooding. These post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high

---

earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in 5-12. Based on the Figure below, the CSU-Channel Islands is connected to areas moderately susceptible to landslide.

Figure 5-13: Deep-Seated Landslide Susceptibility Surrounding CSU-Channel Islands

Extent of the Hazard

Landslides are most likely to occur in the steep slopes and foothills of the Santa Monica Mountains south and east of the CSU Channel Islands campus. However, the indirect impacts of landslides in the region may cover a larger geographical extent. Based on the campus’ close proximity to the landslide hazard zone, and the history of significant impacts in the city of Camarillo, the planning committee ranks the extent of the landslide hazard for the campus as **Moderate**.

History of the Hazard

---

In 2014, a post-fire rockslide and mudslide occurred in Camarillo Springs, approximately 10 miles from CSU Channel Islands. The event occurred after heavy rainfall near the Springs Fire burn scar, destroying 10 homes and damaging 6 homes. Landslides have also occurred in the hillsides surrounding Camarillo in the past. No landslides have occurred on or immediately adjacent to the campus.

Potential Impacts of the Hazard

The CSU Channel Islands campus may be impacted by the disruption of services as a result of landslides in the region or by damage to structures. Students, faculty, and staff who live in nearby communities may also be impacted. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure in the region. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is somewhat related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events and fires, landslides may generally occur more often. Historically, landslides have occurred occasionally in the mountains surrounding Camarillo and therefore are likely to occur in the future. Given the location of the campus adjacent to the landslide zone, and the occasional occurrence of landslides on Camarillo, the planning committee ranks the probability of the landslide hazard for the campus as Possible.

Vulnerability to the Hazard

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. The CSU-Channel Islands campus appears to exhibit building and infrastructure vulnerabilities to some degree based on mapping. See the landslide location map in relation to the campus along with landslide severity zones identified. Campus leadership may decide to assess potential asset vulnerabilities in the future.
Also, any population proximal to a landslide when it occurs is vulnerable to its impacts.

**Estimate of Potential Losses**

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Channel Islands.

**Vulnerability Assessment Conclusions**

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**

The ability to predict future landslides at the CSU Channel Islands campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.
Power Outage

Description of the Hazard

California State University, Channel Islands is located in Ventura County, California. The University campus is in an area of Ventura County known as Channel Islands, made up of an eight-island archipelago located within the Southern California Bight in the Pacific Ocean, off the coast of California. Ventura County has eight facilities dedicated to electrical power with an estimated value of replacement at $31,967,213.

Most aspects of modern life rely on the near continuous availability of utilities, such as electricity, water, and natural gas. An interruption in the supply or distribution of power can affect the campus in various ways like forcing campus closures to limiting campus operations. These interruptions can produce cascading effects from other hazards, such as major windstorms, winter storms and wildfire, which can prompt an intentional disruption or Public Safety Power Shut Off (PSPS).

A power outage event can interrupt day-to-day operations of the campus, like in-person classes, impede, or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center and close restaurants around campus and outside the campus. Additionally, thousands of CSU Channel Islands student residents in on-campus housing would also be affected by a power outage on campus.

Additionally, a severe outage to Ventura County or neighboring communities and cities would also directly affect the campus and the community.

An electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions:

- Planned: Some disruptions are intentional and can be scheduled based on maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO), which is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities. CAISO is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of “stage alerts” to the media based on system conditions. The alerts are as follows:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. That said, only one recorded outage has taken place on campus. As such, the planning committee ranks the extent of the power outage hazard as **Minimal**.

History of the Hazard

CSU Channel Islands has experienced power outages for various reasons. The university works with Southern California Edison, the community’s local electric utility company, to restore energy to the campus for its facilities, assets, resident halls, and classrooms. CSU Channel Islands has not endured many power outages but has encountered a minor disruption due to a loss of power in 2011.
On November 2, 2011, Lieutenant Morris from the Campus Police was informed of a planned power outage by Southern California Edison. A downed pole prompted a power outage at approximately 4pm for twelve hours. The loss of power forced University housing, and campus police to rely on power generators. The campus transitioned to a response strategy by utilizing the various generators it holds and engaging a small team from Unit 6 of electricians and plumbers.

Safety precautions were upheld ensuring campus staff were safely situated within the campus. For some departments, power outages continuing into the morning hours would allow them to not report to work. Additionally, for situational awareness, signage was placed at campus entrances stating that the campus was experiencing a power outage and that the campus was to remain closed until power returned. Campus Police would increase campus security by increasing patrol within empty buildings during the night.

By the following early morning on November 3, the generators were no longer necessary after the power was restored to all campus areas. In approximately ninety minutes the power would be fully restored to the entire campus. A mass message would be disseminated to the campus community that the campus power was fully restored and the University would return to regular campus operations.

Potential Impacts of the Hazard

Instructors, campus residents, staff and administration rely on electricity to maintain ongoing operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, enabling students with disabilities to enter, navigate and leave University buildings and long-term outages can potentially put students, faculty and staff safety at risk. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions and losing power can potentially lead to tragic results.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily
basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. Camarillo and Ventura County experience such outages. As such, the probability ranking for the Camarillo area is **Likely**; although the campus has recorded fewer events than the surrounding area, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate and cope with an interruption to electrical power.

**Estimate of Potential Losses**

Although the economic impact of power outage damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Channel Islands.

**Vulnerability Assessment Conclusions**

The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Channel Islands. Safety and operations protocols center on the following “direct impact” set of concerns:

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary functions to navigate through the campus with ease, maintain a safe campus environment and visibility during nighttime hours. The vulnerable population, like students with physical disabilities may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors and locks and lights may
impede on a student with a disability’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

Cal State Channel Islands did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.

*Tsunami*

Description of the Hazard

A tsunami is a wave triggered by any form of land displacement along the edge or bottom of an ocean or lake. Land displacement can be in the form of submarine landslides or submarine dip-slip faults. These types of faults cause ruptures that result in seafloor uplift or down-drop. This mass movement translates to a tsunami or gravity wave within the overlying water at the surface.

Tsunamis travel radially outward from the area of initiation. The size of a tsunami is proportional to the mass that moved to generate the tsunami. As a tsunami approaches the shore and the depth of the water column decreases, the energy in the wave pushes the wave crest above the water surface resulting in a larger wave height. Wave runup is the elevation above mean sea level on dry land that a tsunami reaches. Run-up is what causes inundation of coastal areas that are below the run-up height.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing severe damage to coastal development. At the shoreline, tsunamis may take the form of a fast-rising tide, a cresting wave, or a bore (a large, turbulent wall-like wave). The bore phenomenon resembles a step-like change in the water level that advances rapidly (from 10 to 60 miles per hour). The first wave is usually followed by several larger and more destructive waves.
Location of the Hazard

According to the 2018 CA State Hazard Mitigation Plan, tsunami locations span 94 incorporated communities and 83 unincorporated areas across 20 coastal counties.

As identified on the maps (below), Ventura County is at risk to the tsunami hazard, although the CSU – Channel Islands campus is located away from the tsunami inundation zone. However, due to its safe location, the campus participates in the county’s emergency operations plan by providing a secure “high ground” location for evacuees from the tsunami zone seeking refuge.

Figure 5-14: Tsunami Inundation Area at CSU-Channel Islands
Extent of the Hazard

The factors shaping the extent or severity of the hazard are a combination of geophysical forces (the amount of vertical and horizontal motion of the sea floor, the area over which it occurs, and the efficiency with which energy is transferred from the earth’s crust to the ocean water) and the geographic range of coastal development to be impacted.

More specifically, as a tsunami approaches the shore, wave run-up is the elevation above mean sea level on dry land that a tsunami reaches. A tsunami’s potential severity can be forecasted as a function of the wave’s mass along with the difference between the wave’s run-up height and the ground elevation of the affected coastal location.

There are two types of source regions for tsunamis—resulting in local and distant source tsunamis as viewed from the affected shoreline. Local tsunamis are typically more threatening because they afford at-risk populations only a few minutes to find safety. California is vulnerable to, and must consider, both types. Identifying tsunami hazards requires 1) evaluating the potential for submarine mass movement both locally and at great ocean distances, and 2) identifying coastal regions within the direct or indirect path of a potential tsunami wave that are below the run-up height.

---

Given the history of tsunami occurrences in Ventura County, and the range of potential impacts to its coastal communities, although the campus lies outside the inundation zone, the planning committee ranks the extent of tsunami as **Moderate**.

**History of the Hazard**

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years. That said, no tsunamis have impacted CSU campus locations.

According to the National Centers for Environmental Information (NCEI), have been eight tsunamis have caused damage to ports and harbors or coastal inundation in California since 1946. **The most significant events are as follows:**

- In 1964, a tsunami caused by a Magnitude 9.2 earthquake offshore from Alaska resulted in 13 deaths in California and destroyed portions of downtown Crescent City.
- A 2006 tsunami (originating in the Kuril Islands region north of Japan) caused approximately $20 million in damage to Crescent City harbor.
- A 2010 tsunami (originating offshore from Chile) caused millions of dollars in damage to ports and harbors in the state.
- A tsunami in 2011 (caused by a Magnitude 9.0 earthquake offshore of Japan) killed one person at the mouth of the Klamath River and caused up to $100 million of damage to 27 ports, harbors, and marinas throughout the State. The most damage occurred in Crescent City, Santa Cruz and Moss Landing harbors and a federal disaster was declared in Del Norte, Santa Cruz, and Monterey Counties. Both Crescent City and Santa Cruz harbors sustained damage to all docks, and oil spills and water/sediment contamination that resulted from sunk or damaged boats. Because recovery efforts in these two harbors took several years to complete, both harbors incurred business/economic losses that have been difficult to recapture.

Although the campus is not in the tsunami zone, eight (8) tsunamis have occurred in Ventura County between 1812 and the present:

**Historical Tsunami Run-Ups in Ventura County**

- 12/21/1812: Earthquake and Landslide City of Ventura 6.5-foot run-up
- 04/01/1946: Earthquake – Aleutian Islands; Alaska Port Hueneme 3-foot /Ormond Beach 5-foot run-up
- 11/4/1952: Earthquake – Kamchatka Peninsula; Port Hueneme 2-foot run-up
- 3/09/1957: Earthquake – Aleutian Islands; Alaska Port Hueneme 2-foot run-up
- 3/28/1964: Earthquake and Landslide – Alaska; City of Ventura Tide dropped 8.0 feet Oxnard Large swells
- 9/29/2009: Earthquake – Samoa; Ventura Buoys moved near mouth of harbor
- 2/27/2010: Earthquake – Chile; Ventura, Oxnard, Port Hueneme 3-foot run-up
03/11/2011: Earthquake – Japan; Ventura, Oxnard 4-foot run-up Port Hueneme 5-foot run-up

Potential Impacts of the Hazard

Tsunamis can travel at speeds of over 600 miles per hour in the open ocean and can grow to over 50 feet in height when they approach a shallow shoreline, potentially causing total devastation to coastal development.

The configuration of the coastline, the shape of the ocean floor, and the characteristics of advancing waves play important roles in the destructiveness of the waves. Bays, sounds, inlets, rivers, streams, offshore canyons, islands, and flood control channels may cause various effects that alter the level of damage. Offshore canyons can focus tsunami wave energy, and islands can filter the energy. It has been estimated that a tsunami wave entering a flood control channel could reach a mile or more inland, especially if it enters at high tide. The orientation of the coastline determines whether the waves strike head-on or are refracted from other parts of the coastline.

CSU - Channel Islands is not at risk to physical impacts from tsunamis. In carrying out its role as an evacuation center, the key potential impact is a depletion or exceedance of campus resources for managing a refugee population during emergency response.

Potential impacts to buildings and infrastructure within the county’s inundation zone include destruction of the natural environment, destruction of boats, as well as other coastal development, and loss of life. Tsunamis that impact both harbors and communities also can produce free-floating debris hazards and environmental contamination from chemical spills. All these factors shape the potential impact to campus EOP-related capabilities.

Probability of Future Occurrence of the Hazard

The California Seismic Safety Commission report, the Tsunami Threat to California Findings and Recommendations on Tsunami Hazards Risks, published in December 2005, indicates that over 80 tsunamis have been observed or recorded along the coast of California in the past 150 years.70 If we consider historical occurrence as one data set for estimating future events, the average rate of occurrence over the past 150 years is 1 tsunami every 7.9 years. Currently, no analysis is available which differentiates this statewide probability specifically for Ventura County, CA. Although 8 events have been recorded for the county over 209 years (1812-2021), it is prudent to utilize the 1.9-year statewide recurrence internal for planning purposes given extreme difficulties predicting tsunami points of origin.

The rate of future occurrence may change and may be able to make target estimates for specific locations in the future; the California State Tsunami Program is trying to refine the accuracy of the data. In doing so, the State Tsunami Program is completing a set of

---

Probabilistic Tsunami Hazard Analysis (PTHA) maps representing risk levels from 100-year to 3000-year average return periods. Analysis using these probabilistically based products will allow for a more common platform for comparison to other seismic and flood probabilistic analyses.

Vulnerability to the Hazard

With regard to CSU campus locations, direct vulnerability of assets and people to tsunami only applies to the CSU Chancellor’s Office in Long Beach, CA, as it is the only campus clearly located in a mapped tsunami zone.

With regard to CSU - Channel Islands’ vulnerabilities, the campus planning committee indicates that due to its role as an evacuee housing and protection facility during tsunami emergency response operations, primary vulnerability is a depletion or exceedance of campus resources in providing response services.

Vulnerability of Populations

For CSU – Channel Islands, population vulnerability is largely reduced through successful evacuation but would pertain to the planning area in its role protecting evacuees.

The populations most vulnerable to the tsunami hazard in Ventura County are the elderly, disabled and very young who reside near beaches, low-lying coastal areas, tidal flats and river deltas that empty into ocean going waters. In the event of a local tsunami generated near the Ventura coast, little warning time would exist, so more of the population would be vulnerable. According to the 2015 Ventura County Multi-Jurisdictional Hazard Mitigation Plan, the areas along the coast of the cities of Ventura, Oxnard, and Port Hueneme and select areas of Unincorporated Ventura County are of most concern.71 The County has established two tsunami evacuation zones, one for a Phase 3 event and one for a Maximum Evacuation Phase. The following percentages of the population live in the evacuation zone for a Maximum Evacuation Phase: Oxnard, 4%, Port Hueneme, 7%, Ventura, 5%, and Unincorporated Ventura County, 4%.

Property Vulnerability

For Ventura County, the impact of tsunami waves and the scouring associated with debris that may be carried in the water could be damaging to all structures along beaches, low-lying coastal areas, tidal flats and river deltas. The most vulnerable structures are those in the front line of tsunami impact and those that are structurally unsound. However, according to the tsunami zone asset mapping for the campus, no assets are located within the inundation zone. The County’s Hazard Mitigation Plan provides a summary of the impacts of a tsunami on the entire County, including the level of impact on landmass, population, residential structures, and critical facilities (Table 5-25).

**Critical Facilities and Infrastructure Vulnerabilities**

No campus critical facilities or infrastructure are vulnerable to physical impacts from a tsunami wave. However, campus EOC-related facilities or infrastructure could be exceeded by the demands associated with housing and protecting tsunami evacuees. That said, the following infrastructure is vulnerable to damage in Ventura County, CA:

- Water Proximate Infrastructure—Breakwaters and piers collapse, sometimes because of scouring actions that sweep away their foundation material and sometimes because of the sheer impact of the tsunami waves.

- Flood Control Systems—Floodwaters can back up drainage systems, causing localized flooding. Culverts can be blocked by debris from tsunami events, also causing localized urban flooding.

- Utility Systems—Floodwaters can get into drinking water supplies, causing contamination. Sewer systems can be backed up, causing waste to spill into homes, neighborhoods, rivers and streams. Tsunami waves can knock down power lines and radio/cellular communication towers. Power generation facilities can be severely impacted by wave action and by inundation from floodwater.

- Fuels—Destruction of fueling infrastructure and related environmental and potable water contamination can occur.

**Estimate of Potential Losses**

Given that the campus is located outside of the inundation zone, an estimate of potential losses from a tsunami wave impact is not applicable at this time.

For Ventura County, estimated dollar losses to vulnerable buildings and infrastructure lying within the inundation zone is not currently available, but will be pursued in the future. A Maximum Level event (8.5 – 11.0 above tide level) would likely produce catastrophic impacts to all property within the inundation zone.

**Vulnerability Assessment Conclusions**

Community exposure to tsunamis in California varies considerably—some communities may experience great losses that reflect only a small part of their community and others may experience relatively small losses that devastate them. Among the 94 incorporated communities and 83 unincorporated areas of the 20 coastal counties, the communities that are most vulnerable to injury and life safety issues exist within Del Norte and Humboldt counties while the cities of Alameda, Belvedere, Crescent City, Emeryville, Oakland, and Long Beach have the highest combinations of the number and percentage of people and businesses in tsunami-prone areas.73

To improve tsunami vulnerability assessments, FEMA has developed a new tsunami loss estimation module for HAZUS using existing numerical model results for tsunami inundation, flow depth, velocity, and force. This HAZUS module allows new capability for estimation of economic losses, and site-specific analysis of content losses, casualties, infrastructure damage, and evacuation time. The module calibrates losses based on safe zones and community preparedness levels. Such technological improvements in assessment capability can be utilized for tsunami hazard analysis and planning purposes for CSU - Channel Islands.

Along with new probability-based tsunami maps, the HAZUS module will improve the ability to compare tsunami impacts to those of other hazards. Moreover, the probability mapping will be used for numerous applications including identifying potential tsunami hazard “zones of required investigation” under the Seismic Hazards Mapping Act and will

---

5-92
assist state and local agencies in making land use planning decisions and will help regional and state planners understand the flood potential from tsunamis representing different risk levels. The improved analysis and data will be utilized by CSU - Channel Islands through its partnerships with key stakeholder organizations.

**Identified Data Limitations**

As identified in the Vulnerability Summary (above), with regard to the current planning effort, the primary data limitations for assessing the tsunami hazard for CSU campuses are comprehensive asset valuations lying within the tsunami inundation zone, and the need to apply FEMA’s new probability mapping techniques and tsunami loss estimation module to the footprint of each campus. That said, CSU leadership and planning teams intends to pursue such data in the future.
Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU Channel Islands or Ventura County is located within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein two (2) inches or more of ashfall following an eruption is possible. While CSU Channel Islands does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic

---

eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Channel Islands is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Channel Islands.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Channel Is, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.

Estimate of Potential Losses
Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

**Vulnerability Assessment Conclusions**

CSU Channel Islands is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

**Identified Data Limitations**

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.
While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire

---

behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- Fuels – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

Location of the Hazard

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. CSU Channel Islands is located along the base of the western edge of the Santa Monica Mountains where they meet the agricultural fields of the Oxnard Plain. Areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur to the east, west, and north of the campus. Additionally, these fire hazard zones exist in other areas throughout Ventura County. These areas surrounding the valley are topographically diverse, contain heavier vegetative fuels, and often have residential development interspersed. The land in the Oxnard Plain where the CSU Channel Islands campus is located, is largely agricultural with some development including the campus.

The CSU Channel Islands campus is located in the southern portion of Ventura County south of the City of Camarillo. The area immediately surrounding the campus is predominately agricultural to the west and open hillsides to the east with residential land uses included. Fire Hazard Severity Zones are found throughout the campus and throughout the hillsides surrounding the campus to include Very High Fire Hazard Severity Zones (VHFHSZ).
Ventura County has multiple areas considered as fire hazard zones that present direct threats of burning potential in areas that are in proximity to those hazard areas. Additionally, these large areas of land that are considered to be hazardous for the potential for fire will also produce the threat of diminished or hazardous air quality due to the smoke and particulates produced in the burning process. The air quality for residents of the County and the CSU Channel Islands campus community can be greatly affected by large fires burning in these areas.

Fire Hazards Zones surrounding southern Ventura County demonstrate the broader community threat that wildfires present to the population. Fire hazard severity zones are found surrounding the populated areas of the county. This presents the potential for fire related damages and smoke inundation to occur in many areas that members of the campus community reside at, are employed in, or where they recreate. Transportation routes are equally impacted causing potential added challenges for the campus community to get to areas if safety, get resources, or gain access to the campus.

Extent of the Hazard

While the threat to fire directly affecting the campus is considerable, the direct effect of fire generated smoke is also likely to occur. Fires are likely to occur in close proximity to the campus generating smoke that could envelop the campus in the right atmospheric conditions. Fires that are large enough to generate volumes of smoke to cover great distances have the potential to affect the air quality of the Ventura County area including the campus. This will especially be the case in weather conditions creating strong off-shore winds. This impact has been demonstrated during the summers of 2018, 2019, and 2020 as fires burned across the state and spread smoke over vast distances. Fires burning well outside of the Ventura County region have the potential to distribute smoke onto the CSU Channel Islands campus.

Given the occurrence of 7 Federal Declarations in Ventura County from 2003 - present, along with the fact that Fire Hazard Severity Zones are found throughout the campus and throughout the hillsides surrounding the campus to include Very High Fire Hazard Severity Zones (VHFHSZ), the planning committee ranks the extent of the wildfire hazard for the campus as **High** – the potential exists for wildfire to occur on three sides of the campus.
campus in the surrounding hillsides composed of light to moderate fuels, and the threat of these neighboring hillsides to campus structures is substantial.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 5-26: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel -- especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CLASS 4: Very High Danger (VH)</th>
<th>Fires start very easily and spread at a very fast rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Orange</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CLASS 5: Extreme (E)</th>
<th>Fire situation is explosive and can result in extensive property damage</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLOR CODE: Red</td>
<td>Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.</td>
</tr>
</tbody>
</table>

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.
<table>
<thead>
<tr>
<th>Daily AQI Color</th>
<th>Levels of Concern</th>
<th>Values of Index</th>
<th>Description of Air Quality</th>
</tr>
</thead>
<tbody>
<tr>
<td>Green</td>
<td>Good</td>
<td>0 to 50</td>
<td>Air quality is satisfactory, and air pollution poses little or no risk.</td>
</tr>
<tr>
<td>Yellow</td>
<td>Moderate</td>
<td>51 to 100</td>
<td>Air quality is acceptable. However, there may be a risk for some people, particularly those who are unusually sensitive to air pollution.</td>
</tr>
<tr>
<td>Orange</td>
<td>Unhealthy for Sensitive Groups</td>
<td>101 to 150</td>
<td>Members of sensitive groups may experience health effects. The general public is less likely to be affected.</td>
</tr>
<tr>
<td>Red</td>
<td>Unhealthy</td>
<td>151 to 200</td>
<td>Some members of the general public may experience health effects; members of sensitive groups may experience more serious health effects.</td>
</tr>
<tr>

<td>Very Unhealthy</td>
<td>201 to 300</td>
<td>Health alert: The risk of health effects is increased for everyone.</td>
</tr>
<tr>
<td>Maroon</td>
<td>Hazardous</td>
<td>301 and higher</td>
<td>Health warning of emergency conditions: everyone is more likely to be affected.</td>
</tr>
</tbody>
</table>

### History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Ventura County also has a long history of wildfire activity primarily in the foothills and mountains of the Transverse Range and the Santa Monica Mountains. Wildfires occurring in Ventura County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damages. During the past 50 years, 23 wildfires have resulted in greater than 10,000 acres burned in the County.

---

The area immediately surrounding the CSU Channel Islands campus is in proximity to fire hazard zones designated as Very High Fire Hazard Severity Zones (VHFHSZ). Additionally, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Channel Islands campus has experienced multiple days of poor air quality due to fires burning in Ventura County and neighboring counties. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Ventura County. CSU Channel Islands personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

*Fire occurred in both Los Angeles County and Ventura County

**Fire occurred in both Santa Barbara County and Ventura County

Fire has contributed significantly to Ventura County’s hazard and disaster history. Some particular fires that have shaped the way fire plays into preparedness, planning, response, recovery, and mitigation efforts are described in the following.

The 2013 Springs Fire occurred in the hills immediately east of the CSU Channel Islands campus. The fire forced the evacuation of the campus along with several neighborhoods. The fire started on May 2, 2013 as heavy Santa Ana Winds and low humidity were present. The 40-50 mile per hour winds allowed for rapid rate of spread and difficult suppression conditions. The fire burned up to the CSU Channel Islands campus and areas of study of rare species of plants.

---

The December 4, 2017 Thomas Fire in Santa Barbara and Ventura Counties burning in the hills and mountains of the Transverse Range burned a total of 281,893 acres in moderate to heavy fuels. A high wind event caused high voltage power lines to come into contact with one another creating an electrical arc. The arc dropped hot molten material to the ground into an area experiencing low humidity and low fuel moistures combined with the high winds. The fire demonstrated extreme fire behavior during red flag fire warning conditions. The powerline caused fire forced the evacuations of over 100,000 people, destroyed 1,063 structures, damaged hundreds more, and killed 2 people. The Thomas Fire would become the state’s largest wildfire in history until being surpassed in 2018. The fire was contained on January 12, 2018 and ultimately caused more than $2.2 billion in damages. The CSU Channel Islands campus was not directly threatened by the Thomas Fire.

The Woolsey Fire ignited on November 8, 2018 and burned in Los Angeles and Ventura Counties. Ultimate, the fire would consume 96,949 acres of land, 1,643 structures were destroyed, 364 additional structures were damaged, over 250,000 people were evacuated, and 3 people were killed. The fire would cost approximately $6 billion in damages and fire suppression costs.

The Day Fire was the largest fire of the 2006 wildfire season in California. The fire was ignited on September 4, 2006 as a result of arson. The majority of the fire occurred on the Los Padres National Forest but also burned nearby private lands. Eleven structures were destroyed, and 162,702 acres were burned.

Potential Impacts of the Hazard

The location of the CSU Channel Islands campus surrounded by areas designated as Very High Fire Hazard Severity Zones places a direct threat that flame, ember, and smoke exposure from wildfire to the campus. There is potential for fire to occur on three sides of the campus in the surrounding hillsides composed of light to moderate fuels. The threat of these neighboring hillsides to campus structures is substantial.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction of damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
- Psychological impacts of impacted populations
- Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:
- Dangerous levels of air pollution
- Human Health Effects
  - Similar health impacts to pets
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems
- Reduced outdoor work productivity
- Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Ventura County including the campus may be damaged resulting in power outages. Fire-related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

**Probability of Future Occurrence of the Hazard**

Based on the wildfire threat potential in the area on and surrounding the CSU Channel Islands campus, including the immediate proximity to Fire Hazard Severity Zones listed as “Very High”, the density of residential and commercial development, and the historic occurrences of fires, the probability of annual wildfire related damage on campus is considered **Possible**.

Based on the wildfire threat potential in the area surrounding the campus and the Camarillo region, including the volume of areas in elevated Fire Hazard Severity Zones throughout the Ventura County valleys, and the historic occurrences of smoke, the probability of wildfire generated smoke impacts to air quality is considered **Possible**.

**Vulnerability to the Hazard**

The CSU Channel Islands campus is subject to direct impact from wildfire due to the campus location within a wildland-urban interface zone. The campus is identified to
reside within a designated local Very High Fire Hazard Severity Zone. The campus is surrounded on three sides by hillsides and open lands containing combustible vegetation. Additionally, vulnerabilities to the effects of wildfire would lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones in other parts of the surrounding region. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of vegetation fires along the hillsides and extending onto the campus or localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have significant impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

Access to the east using Potrero Road servicing portions of Los Angeles County would likely be cutoff during fire incidents. Access for supplies, equipment, and emergency services in addition to evacuation away from the campus would likely be forced to use western routes towards Oxnard or north to Camarillo.

Additional concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The past few summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Sacramento Valley even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Channel Islands students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU Channel Islands campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the
human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $179,257,992. However due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher.

**Table 5-29: Wildfire Hazard Potential (WHP) Zone Estimated Losses**

**Vulnerability Assessment Conclusions**

The occurrence of wildfires has been a frequent event in Ventura County, including wildfire incidents that have threatened or caused damages near the CSU Channel Islands campus. The location of the CSU Channel Islands campus surrounded by open hillsides with light to moderate vegetative fuels along the entire eastern edges presents a threat of fire to the campus community and campus assets. The foothills and mountains surrounding Ventura County host environments that are ideal for the development of wildfire activity. The consequences of fires in these areas would present primary and
secondary consequences to the CSU Channel Islands campus and expose vulnerabilities
on the campus and to the campus community.

The topography of the valley surrounded by mountains allows for smoke filled air to
linger in the valleys of Ventura County area with the potential for unhealthy air quality
depending on wind conditions. Fires in the watersheds of the Santa Monica Mountains
and the Transverse Ranges and tributaries may damage vegetation stabilizing hillsides
and result in increased sediments to be discharged into the river system and reservoirs
reducing their capacity and effectiveness. Communities located within or near the
Wildland Urban Interface may be subject to damaging fires. These same communities
may be home to members of the campus community. The potential for large-scale
wildfires in the region further generates the added potential for a number of cascading
effects such as disruptions to the local economy, utility failures, disruptions to providing
for the needs of the community, and development of public health hazards. The potential
for large-scale wildfires and resulting damage of homes and businesses has
exponentially powerful impacts on particular populations among the campus community
including those with access or functional needs, international students, the homeless, and
students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction
types to include status of earthquake retrofitting. HAZUS generated analysis is focused
on the broader community level versus finetuning the analysis to the micro-level for
facilities such as a university campus.

Severe Weather (Wind, Tornado, Hail, and Lightning)

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are
beyond or near the ends of the range of observed weather patterns and behavior. These
events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves,
unusually cold temperatures, extreme rainfall, and flooding. According to the
Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or
extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail,
lighntning, tornado, etc.) must be “above (or below) a threshold value near the upper (or
lower) ends of the range of observed values of the variable.”

Mclnnes, M. Rahimi, M. Reichstein, A. Sorteberg, C. Vera, and X. Zhang, 2012: Changes in climate extremes
and their impacts on the natural physical environment. In: Managing the Risks of Extreme Events and
Disasters to Advance Climate Change Adaptation [Field, C.B., V. Barros, T.F. Stocker, D. Qin, D.J. Dokken, K.L.
Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU Channel Islands.

**Regional Climate Influences on Severe Weather across California**

Most of the weather in California is influenced by the wet-winter/dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.89

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU Channel Islands), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.90

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.91 The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.92 These storms affect (in varying degrees) all CSU campuses, including CSU Channel Islands.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.93 Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike

90 Retrieved on 07.17.2021 from [https://wrcc.dri.edu/Climate/narrative_ca.php](https://wrcc.dri.edu/Climate/narrative_ca.php)
Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding. Severe thunderstorms are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.
- **Wind storm**: marked by high wind with little or no precipitation.
- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.
- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.
- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.
- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially
ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.103

Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning

This hazard profile concentrates on the following types of severe weather hazards: wind hazards (including tornadoes), hail, and lightning. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

Wind Hazards

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.104 Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”105

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU Channel Islands).

High Winds, Strong Winds, and Thunderstorm Winds

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.106

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\textsuperscript{107}

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\textsuperscript{108}

Please note: \textit{Straight-line wind} is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\textsuperscript{109} However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

Tornadoes

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\textsuperscript{110} This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\textsuperscript{111} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{112}

\textbf{Santa Ana Winds}. A type of wind hazard that is peculiar to Southern California is called a \textit{Santa Ana Wind}. Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico).\textsuperscript{113} They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from

\textsuperscript{109} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/wind/types/  
\textsuperscript{110} Retrieved on 07.15.2021 from https://www.nssl.noaa.gov/education/svrwx101/tornadoes/faq/  
\textsuperscript{111} Retrieved on 07.15.2021 from https://www.weather.gov/bgm/severedefinitions  
September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape.\textsuperscript{114} (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

Table 5-30: What Drives a Santa Ana Wind?\textsuperscript{115}

---

\textbf{What Drives a Santa Ana Wind?}

1. High surface pressure builds over the Great Basin region with lower pressure off Southern Cal Coast. (Fall-mid Spring)

2. Air remains relatively cold across the deserts. As the air extends through the mountain passes...it become compressed and warms. (See lower right map) Lower relative humidity also occurs helping to dry out vegetation and can fan any existing fires.

3. Wind speed increases as it squeezes through the mountain and valley canyons. Wind gusts can vary from 45 to 100 mph depending on the strength of the Santa Ana event.

4. Strong winds create turbulence for area flights and can make interstate travel difficult as well as choppy seas for mariners.

---

\textbf{Diablo Winds}. The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and

\textsuperscript{115} Retrieved on 07.14.2021 from https://twitter.com/nwslosangeles/status/933049473034579968
extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.116

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can even reach hurricane force (≥74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.117 118 119

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.120 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.121

---

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.¹²²

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.¹²³ Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including either at the CSU Channel Islands main campus or at satellite campus facilities owned by the school. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all CSU Channel Islands campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU Channel Islands campuses reflect those of the surrounding community and County. As a result, all assets and people at CSU Channel Islands campuses are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Camarillo (Ventura County) and Goleta (Santa Barbara County) areas, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

---

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. First developed in 1805, it is still used today to estimate wind strengths.

</tbody>
</table>
Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.

**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{127}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the **date** that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 5-32: **Fujita Tornado Scale (Pre-February 2007)** \(^{128}\)

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms. That said, according to the *Glossary of Meteorology* published by the American Meteorological Society (AMS), a thunderstorm is reported as *light, medium, or heavy* according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- **Airmass Thunderstorm**: A thunderstorm produced by local convection within an unstable air mass;
- **Frontal Thunderstorm**: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;
- **Squall-line Thunderstorm**: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as **LOW**.

History of the Hazard

Severe weather hazards have been an annual occurrence in both Ventura County and Santa County, and on the CSU Channel Islands main campus, satellite campus, and other University-owned facilities. Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type.\(^{139}\) For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events.\(^{140}\) To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**Ventura County**

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Ventura County since 1996.\(^{141}\) Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.\(^{142}\)

- **High Wind:** at least 233 events, or approximately 9.20 events per year\(^{143}\)

---

\(^{141}\) National Climatic Data Center. Storm Events Database. Retrieved on 07.29.2021 from https://www.ncdc.noaa.gov/stormevents/

\(^{143}\) National Climatic Data Center. Storm Events Database. Retrieved on 07.29.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29%2BHigh%2BWind&beginDate_mm=01&beginDate_dd=01&beginDate_yyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyy=2021&county=VENTURA%3A111&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA
- **Strong Wind**: at least 3 events, or 0.12 events per year\(^\text{144}\)

- **Thunderstorm Wind**: at least 10 events, or approximately 0.39 events per year\(^\text{145}\)

- **All Wind Hazard events** (excluding Tornadoes): at least 240 events, or approximately 9.47 events per year.\(^\text{146}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Ventura County, there have been at least **240** wind hazard events since 1996, excluding tornadoes.\(^\text{147}\) That translates to an approximate average historical frequency of occurrence of **9.47** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 246 events) and simultaneous Database searches of all severe weather hazard events (i.e., 240 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Ventura County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^\text{148}\)

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 240 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical Wind Hazard Losses for Ventura County since 1996

According to the NCEI Storm Events Database, the wind hazard events that Ventura County has experienced since 1996 have been costly. There has been 1 death associated with wind hazards; however, there have been no injuries, or property and crop damage.\textsuperscript{149}

\textbf{Tornado Wind Hazards}

Information from the NCEI Storm Events Database indicates that since 1996, there have been 5 reported events of tornadoes in Ventura County, which translates to approximately 0.20 tornado events per year.\textsuperscript{150} All tornado reports in Ventura County since 1996 have been of tornadoes with a severity rating of F0/EF0.\textsuperscript{151}

Historical Tornado Hazard Losses for Ventura County since 1996

According to the NCEI Storm Events Database, the tornado hazard events that Ventura County has experienced since 1996 have not generated any known losses; no deaths, injuries, or property or crop damage have been reported in Ventura County from tornado hazard events.\textsuperscript{152}

\textbf{Hail}

Information from the NCEI Storm Events Database indicates that since 1996, there have been three (3) reported events of hail in Ventura County, which translates to approximately 0.12 hail events per year.\textsuperscript{153} (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of four (4) reports of hail since 1996.)

\end{footnotesize}
However, one (1) entry is for a hail event in San Diego County, hundreds of miles away from Ventura County. The origin of this discrepancy is unknown at this time.

**Historical Hail Hazard Losses for Ventura County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Ventura County has experienced since 1996 have generated no known losses. There have been no deaths, injuries, or property or crop damage reported.\(^\text{154}\) (Note: The San Diego County hail event that was included erroneously in the search results for hail events in Ventura County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been two (2) reported events of lightning in Ventura County, which translates to approximately \(0.08\) lightning events per year.\(^\text{155}\)

**Historical Lightning Hazard Losses for Ventura County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Ventura County has experienced since 1996 have been costly. While there have been no deaths, or property or crop damage, there have been 3 injuries associated with a lightning strike that occurred in 2011.\(^\text{156}\)

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database (Ventura County)**

Information obtained from the NCEI Storm Events Database indicates that there have been 250 occurrences of the severe weather hazard in Ventura County. This translates to 9.87 severe weather hazard occurrences per year.\(^{157}\)

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 256 events) and simultaneous Database searches of all severe weather hazard events (i.e., 250 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado;” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Ventura County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{158}\)

When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 250 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Ventura County since 1996**

According to the NCEI Storm Events Database, the severe weather hazard events that Ventura County has experienced since 1996 have been costly. There has been 1 death and 3 injuries, but no property or crop damage.\(^{159}\) However, it is important to note that for all Ventura County severe weather hazard events recorded on the Storm Events Database, all deaths and injuries have been caused by wind hazard events alone.

**Santa Barbara County**

*Wind Hazards (excluding Tornadoes)*

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Santa Barbara County since 1996.\(^{160}\)

---

The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Santa Barbara County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Santa Barbara County has experienced since 1996 have been costly. While there have been no deaths, there have been three (3) injuries, and crop damage estimates have totaled approximately $15,000,000; no property damages have been reported.

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been three (3) reported events of tornadoes in Santa Barbara County, which translates to approximately 0.12 tornado events per year. All tornado reports in Santa Barbara County since 1996 have been of tornadoes with a severity rating of F0/EF0.

**Historical Tornado Hazard Losses for Santa Barbara County since 1996**

According to the NCEI Storm Events Database, there have been no deaths, injuries, property damage or crop damage from tornadoes since 1996.
Hail

Information from the NCEI Storm Events Database indicates that since 1996, there have been four (4) reported events of hail in Santa Barbara County, which translates to approximately 0.20 hail events per year.172 (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of five (5) reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, almost 200 miles away from Santa Barbara County. The origin of this error is unknown at this time.)

Historical Hail Hazard Losses for Santa Barbara County since 1996

According to the NCEI Storm Events Database, the hail hazard events that Santa Barbara County has experienced since 1996 have been minimal. There have been no deaths and only one (1) injury reported; there have been no reports of property or crop damage.173 (Note: The San Diego County hail event that was included erroneously in the search results for hail hazard events in Santa Barbara County accounted for almost all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

Lightning

Information from the NCEI Storm Events Database indicates that since 1996, there have been no reported events of lightning in Santa Barbara County.174

Historical Lightning Hazard Losses for Santa Barbara County since 1996

Because there have been no lightning hazard events reported in the County since 1996, there have been no lightning-related deaths, injuries, property damage, or crop damage.175

All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database

(Santa Barbara County)

Information obtained from the NCEI Storm Events Database indicates that there have been 172 occurrences of the severe weather hazard in Santa Barbara County. This translates to 6.79 severe weather hazard occurrences per year.¹⁷⁶

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 178 events) and simultaneous Database searches of all severe weather hazard events (i.e., 172 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado," and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Santa Barbara County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.¹⁷⁷ When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 172 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

Historical, Aggregated Severe Hazard Losses for Santa Barbara County since 1996

According to the NCEI Storm Events Database, the severe weather events that Santa Barbara County has experienced since 1996 have been costly. While there have been no deaths or property damage, there have been four (4) injuries, and crop damage estimates have totaled approximately $15,000,000.¹⁷⁸ It is important to note that for all Santa Barbara County severe weather hazard events recorded on the Storm Events Database, almost all injuries and all property damage have been attributed wind hazard events alone.

Wind Hazards Not Included in the NCEI Storm Events Database

Santa Ana Winds

Santa Ana wind events occur at least twice per month from October through April.\textsuperscript{179} From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of \textbf{32 occurrences per year}. Typical Santa Ana wind events last 1–2 days and represent 27\% of the occurrences, with events lasting up to 6 days accounting for 90\% of all occurrences. The remaining 10\% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{180, 181}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

**Diablo Winds**

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^{184}\)

---

Sundowner Winds

Strong sundowner wind events occur approximately 2-3 times per year. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.187

Historical Frequency of All Severe Weather Hazards

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within CSU Channel Islands campus areas are at risk from the effects of severe weather hazards.

**Wind Hazards (Including Tornadoes)**

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU Channel Islands campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.
Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

**CSU Channel Islands Main Campus, Camarillo (Ventura County)**

According to the 2015 Ventura County Multi-Hazard Mitigation Plan, the high wind hazard component of “winter storms” is considered to be significant, and may have a moderate potential impact on the County and on the CSU Channel Islands main campus. Because the County is at very low risk from tornadoes, and tornadoes are not included in any hazard profile of the Plan, the potential impacts from tornadoes are considered to be minimal for the County and for the CSU Channel Islands main campus.

**CSU Channel Islands – Extended University Campus, Goleta (Santa Barbara County)**

According to the 2017 Santa Barbara County Multi-Jurisdictional Hazard Mitigation Plan, the County is susceptible to “windstorm” hazards, primarily from Sundowner Winds; as a result, wind hazards (excluding tornadoes) are considered to have moderate potential impact on the County, and therefore on the CSU Channel Islands Extended University Campus. Because the County is at very low risk from tornadoes, the potential impacts from tornadoes are considered to be minimal for the County and for the CSU Channel Islands Extended University Campus.

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

**CSU Channel Islands Main Campus, Camarillo (Ventura County)**

According to the 2015 Ventura County Multi-Hazard Mitigation Plan, the hail hazard component of “winter storms” is considered to be a hazard that may accompany winter storms, but it is not a significant hazard in and of itself. As a result, it has a minimal potential impact on the County and on the CSU Channel Islands main campus.

**CSU Channel Islands – Extended University Campus, Goleta (Santa Barbara County)**

The 2017 Santa Barbara County Multi-Jurisdictional Hazard Mitigation Plan states that while the County is susceptible to hail hazards, there is no current of hailstorms in the County. As a result, hail hazards are considered to be of low significance, and therefore to

---

have a minimal potential impact on the County and on the CSU Channel Islands Extended University Campus.\textsuperscript{191}

\textbf{Lightning}

Lightning strikes the United States about 20-25 million times a year.\textsuperscript{192} Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.\textsuperscript{193} Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.\textsuperscript{194} (Commercial claim payouts for lightning losses for the U.S. were not available.)

\textbf{CSU Channel Islands Main Campus, Camarillo (Ventura County)}

According to the 2015 Ventura County Multi-Hazard Mitigation Plan, the lightning hazard component of “winter storms” is considered to be a hazard that may accompany winter storms, but it is not a significant hazard in and of itself. As a result, it has a minimal potential impact on the County and on the CSU Channel Islands main campus.\textsuperscript{195}

\textbf{CSU Channel Islands – Extended University Campus, Goleta (Santa Barbara County)}

The 2017 Santa Barbara County Multi-Jurisdictional Hazard Mitigation Plan does not include lightning as a hazard, and only mentions it within the context of wildfire ignition. As a result, lightning hazards are considered to be of low significance, and therefore to have a minimal potential impact on the County and on the CSU Channel Islands Extended University Campus.\textsuperscript{196}

\textbf{Probability of Future Occurrence of the Hazard}

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity.

\textsuperscript{194} Retrieved on 07.21.2021 from https://www.iii.org/table-archive/20504

CSU Channel Islands Main Campus, Camarillo (Ventura County)

The 2015 Ventura County Multi-Hazard Mitigation Plan states that a “winter storm” with high winds, hail, and lightning can occur every year in the County.\textsuperscript{197} Also, according to the NCEI Storm Events Database, severe weather wind hazard events have occurred in Ventura County considerably more than once per year – at an average of 9.47 events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Channel Islands main campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU Channel Islands main campus reflect those of the surrounding community and County.

Based on the data available from both the 2015 Ventura County Multi-Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU Channel Islands main campus \textit{at least once on an annual basis}. Therefore, the probability of future occurrence of the severe weather hazard for CSU Channel Islands main campus is \textbf{HIGHLY LIKELY}.

CSU Channel Islands Extended University Campus, Goleta (Santa Barbara County)

The 2017 Santa Barbara County Multi-Jurisdictional Hazard Mitigation Plan states that windstorms are an annual occurrence.\textsuperscript{198} Also, according to the NCEI Storm Events Database, some of these same severe weather hazards have occurred in Santa Barbara County far more than once per year – at an average of 6.51 events per year since 1996. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Channel Islands Extended University campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU Channel Islands Extended University campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available from both the 2017 Santa Barbara County Multi-Jurisdictional Hazard Mitigation Plan and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) CSU Channel Islands Extended University campus \textit{at least once on an annual basis}. Therefore, the probability of future occurrence of the severe weather hazard for the campus is \textbf{HIGHLY LIKELY}.

**CSU Channel Islands – All Campus Areas**

The probability of future occurrence of the severe weather hazard for all CSU Channel Islands campus areas is **HIGHLY LIKELY**.

The following tables show the probabilities of future occurrence for component severe weather hazards for CSU Channel Islands campuses and facilities in Ventura County and San Barbara County.

Table 5-38: Severe Weather Hazard Probabilities of Future Occurrence for Ventura County: CSU Channel Islands Main Campus (Camarillo) and Boating Center (Oxnard)

Vulnerability to the Hazard

People, structures, and assets in all CSU Channel Islands campus areas are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. Both CSU Channel Islands campuses also have vehicles and other off-campus facilities that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects all CSU Channel Islands campus areas. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within all CSU Channel Islands campus areas at risk from severe weather. There are approximately 62 buildings on the main campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement
costs due to severe weather hazard are $179,257,992 for 32 buildings, and unknown for the remaining 30 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is also not currently available, though CSU leadership may pursue such data in the future.

The population at the CSU Channel Islands campus varies throughout the day. As of Fall, 2019, CSU Channel Islands had 7,093 students and 994 faculty and staff. All are at risk from severe weather events, with 8,087 being directly vulnerable in this scenario.

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to CSU Channel Islands campuses. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU Channel Islands.

It is evident that CSU Channel Islands has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.

5.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Channel Islands campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.
Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”

Table 5-40: High level summary of campus populations of concern

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (housing insecurity), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (undocumented, DACA, etc.), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:
- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees, the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.
Table 5-41: Campus-specific emergency management issues of concern and inclusion in emergency management plans and processes.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- High number of students are on the Autism Spectrum
- Strongly concerned about the number of students with food insecurity though students can reach to a Care Team and be given a voucher
- Mental health issues were noted with concern regarding the community shooting in recent years because many students had friends who died; quite a few students dropped out of school; strong psychology services on the campus have supported
- Issue of racial equity was cited as being a significant issue of concern (and for the campus overall, one of the biggest concerns for the President); not sure about the how it is reflected in the EM plans
- Catch 22 on communications regarding when someone with COVID is in and in a building but folks on campus want to know where the person is but they are not allowed to identify the person or the building
Immigrants/immigration status issues was cited as a very high issue of concern; after recent events when there was going to be a major impact to DACA students, there was much discussion but not part of EM planning

Previously issues with transportation during the wildfires but now involved in the country EM planning which will relieve the issues if evacuation is needed

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and details for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of some the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

Table 5-42: CSU Channel Islands *Highly Likely, Likely and Possible* Hazards

*Communicable Diseases*

**TBD**

*Drought*

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on
subsistence fishing for their livelihoods. Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states. Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental

---

disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.\textsuperscript{203}

\textit{Erosion}

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

\textit{Flood}

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. \textsuperscript{204}

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural health and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, sadness and grief. Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

**Landslides**

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied buildings which makes it a function of structural vulnerability and therefore, indirect. The degree of vulnerability to landslides by an individual considered at high risk, or even the general populations, also depends on human behavior, including many of the traditional social factors that are difficult to measure such as situational awareness, prior knowledge of hazards, and decision-making capabilities.

Landslides can result in primary lifeline failures through the loss of roads or power and communication lines. Transportation routes are often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods. Risk from landslide relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

---

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Tsunami**

**TBD**

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. 207 Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.208

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following:209 particulate matter, surface levels of ozone,

---

carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.\textsuperscript{210}

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.\textsuperscript{211}

**Hazard Mitigation and Emergency Management Planning**

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

6.1 University Profile

University History

California State University, Chico (CSU Chico) was opened in 1889 as a normal school and began awarding baccalaureate degrees in 1924. It became a charter institution of the California State University System in 1972 and changed its name to California State University, Chico. In 2015, CSU Chico became a federally recognized Hispanic-Serving Institution, and maintains that designation today. The school includes seven colleges and is classed as a Master’s College by the Carnegie Institute.

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The CSU Chico University Advisory Board advises the development of programs and acts as a liaison between the institution, community, legislators, and other groups. It is made up of citizens from throughout the state.

The Academic Senate formulates academic, personnel, and professional policies, including fiscal policies. It consists of thirty-one elected and ten ex officio faculty members, the former of which are elected and may include faculty, staff, administrators, and students. There are more than thirty committees to which the Senate makes appointments.

University Mission

“Through excellence of inquiry, innovation, and experiential learning, we develop students who are critical thinkers, responsible citizens, diverse leaders, and inspired stewards of environmental, social, and economic resources.”

CSU Chico outlines three strategic priorities in support of their goals: Equity, Diversity, and Inclusion; Civic and Global Engagement; and Resilient and Sustainable Systems. These priorities aim to develop a welcoming campus with equitable opportunities, stronger connections with external communities, and sustainable environmental, social, and economic systems.

University Location

The 132-acre CSU Chico campus is located in Chico in central northern California, 90 miles north of Sacramento. Chico, a city of approximately 100,000, is situated between the Sacramento River and Sierra Nevada foothills. In addition to its core campus, the University also manages 800 acres of farmland and 4,043 acres of ecological reserves.
University Population

CSU Chico typically enrolls over 17,000 students per year. During the 2019-2020 school year, the student population was overwhelmingly made up of undergraduate degree seekers, among whom the average age is 22. White/Non-Hispanic students made up 43.6% of all students, with Hispanic/Latino students making up the second most populous group at 34%. Half of all students are first generation.

In addition to the student population, the University is home to 2,048 employees.

6.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate..

Requirement §201.6(c)(2)(ii)(C): [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

Requirement §201.6(c)(2)(iii): For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.
6.3 Hazard Identification and Risk Assessment

Overview of California State University, Chico History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s How-To Series, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered XX hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 6-1 (following).

Table 6-1: Hazard Identification Determinations

<table>
<thead>
<tr>
<th>Hazard</th>

### Future Occurrence Probability

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely** - 76-100% that the hazard would occur annually.
- **Likely** - 50-75% that the hazard would occur annually.
- **Possible** - 11-49% that the hazard would occur each annually.
- **Unlikely** - 0-10% that the hazard would occur each annually.

*Note: The table above provides a summary of the hazards and their likelihood of occurrence on campus.*
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague).

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See table below.)

Descriptions of Identified Communicable Disease Hazards at CSU Chico

CSU Chico has identified two (2) communicable disease hazards that have had the greatest impact on campus – COVID-19 and Tuberculosis. The following are brief descriptions of the communicable disease hazards at CSU Chico.

COVID-19 (SARS-CoV-2)

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.
The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes (i.e., airborne transmission). It’s not yet known how commonly the virus spreads this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main form of transmission.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. Others may experience shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness. In some cases, the disease can cause severe medical complications and may even lead to death.⁵

**Tuberculosis (TB)**

TB is a potentially serious infectious disease that mainly affects the lungs. TB is caused by bacteria that spread from person to person through microscopic droplets released into the air. This can happen when someone with the untreated, active form of TB coughs, speaks, sneezes, spits, laughs or sings.

Although TB is contagious, it’s not easy to catch. It is more likely for someone to get TB from a close family member or coworker than from a stranger. Most people with active TB who have had appropriate drug treatment for at least two weeks are no longer contagious. However, many strains of TB resist the drugs most used to treat the disease. People with active TB must take several types of medications for many months to eradicate the infection and prevent development of antibiotic resistance.⁶

**Location of the Hazard**

Communicable diseases have the potential to affect the entire CSU-Chico (Chico State) planning area. As a result, this hazard can be found at the CSU Chico campus located in

---

Chico, CA (Butte County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff, and visitors to CSU-Chico are at risk of exposure⁷.

**CSU Student Housing Locations and Populations**

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For CSU – Chico, approximately 12% of its 17,019 enrolled students or 2100 students reside in student housing⁸,⁹.

**Extent of the Hazard**

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard. Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 6-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

---

The Extent of CSU Chico Communicable Disease Hazards Except COVID-19:

Before the COVID-19 pandemic, there were cases of Tuberculosis at CSU Chico. Tuberculosis would be classified at either the BSL-2 or BSL-3 containment level.\textsuperscript{11}

The Extent of CSU Chico COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.\textsuperscript{12}

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported \textbf{325} cases of COVID-19 at CSU Chico. CSU-campus-specific COVID-19 case data for CSU Chico can be found in the \textit{History of the Hazard} section below.

\textbf{History of the Hazard}

Most communicable disease data are maintained by the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level

\textsuperscript{11} Stanford Environmental Health & Safety. \textit{Biosafety Levels for Biological Agents}. Retrieved 03.31.2021 from: \url{https://ehs.stanford.edu/reference/biosafety-levels-biological-agents}

case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located. The following table (6-6) includes confirmed COVID-19 cases involving CSU-Chico students, faculty or staff who may have exposed others while working, visiting, attending in-person instruction, or living on campus (student housing) during the illness and total cases and deaths in Butte County.

Table 6-4: Comparison of Cases at CSU Chico and in Butte County (as of 03.22.2021)

<table>
<thead>
<tr>
<th>COVID-19 Cases at CSU Chico</th>

</thead>
<tbody>
<tr>
<td>As of 03/22/2021, there were a total of 325 positive COVID-19 cases identified in the Chico State community since August 1, 2020. This total is updated on a weekly basis every Friday afternoon.</td>
<td>Total Cases: 10,975</td>
</tr>
<tr>
<td></td>
<td>Total Deaths: 171</td>
</tr>
</tbody>
</table>

*These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)*

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system (including the CSU – Chico campus). The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU – Chico students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic, and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU – Chico) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme

BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 6-5: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 6-9 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level

---

for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 6-6: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>

<td>These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.</td>
</tr>
</tbody>
</table>

17 CDC/National Institutes of Health. *Biosafety in Microbiological and Biomedical Laboratories, 6th Ed.* Print. Retrieved 05.03.2021 from: [https://www.cdc.gov/labs/BMBL.html](https://www.cdc.gov/labs/BMBL.html)
These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL-4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

**Probability of Future Occurrence of the Hazard**

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.

Table 6-10 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
</table>

Table 6-7: Likelihood of Future Hazard Occurrence
Highly Likely | 76 – 100% probability that hazard will occur annually (high to very high frequency)
Likely | 50 – 75% probability that hazard will occur annually (moderate to high frequency)
Possible | 11 – 49% probability that hazard will occur annually (low to moderate frequency)
Unlikely | 0 – 10% probability that hazard will occur annually (very low to low frequency)

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s system-wide probability ranking reflects the ranking at the individual CSU campus level unless noted otherwise.

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at CSU campuses.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, the CSU System had 480,541 students and 53,763 faculty and staff.)\(^{18,19}\) Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree on campus in the current COVID-19 pandemic.

Estimate of Potential Losses

**COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities**

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU – Chico) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities.\(^{20}\) The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system.

\(^{18}\) The California State University. *Enrollment*. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

\(^{19}\) The California State University. *Employee Head Count by Campus*. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx

(Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Figure 4-5 below for the economic impact to the CSU – Chico campus). Several CSU campuses saw refund losses surpass $10 million. (See Figure 6-2).
Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 6-13). However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

**Vulnerability Assessment Conclusions**

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable
disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems.

See Table 6-10 below for the “10% outbreak scenario” projections for the CSU – Channel Islands campus and for the entire CSU system:

Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system (including CSU - Chico). In
short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).

**Dam and Levee Failure**

**Description of the Hazard**

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish
flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from over toppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

Location of the Hazard

Butte County is home to a variety of flood control facilities and levee systems throughout the county. Chico sits at the base of the northern Sierra Mountains. There are dam facilities in the higher elevations to the east of the city.

The county is additionally downstream of facilities located in other counties. There are additional dam facilities north of the city in Shasta County containing significant amounts of water. Shasta Dam and Whiskeytown Dam feed into the Sacramento River. Failures of these facilities are expected to produce inundations that cover much of the northern Sacramento Valley but are projected to come within 2-3 miles and not enter Chico.

The Feather River feeds into Lake Oroville a reservoir created by the Oroville Dam. The dam is a California Department of Water Resources dam only a few miles upstream from Oroville, California. The Feather River drains a watershed of 3,604 square miles potentially producing tremendous amounts of runoff. This river system flows downstream from and away from Chico. However, important transportation routes from

the Sacramento area are within the inundation area. Additionally, the cities below the Oroville Dam are communities that members of the campus community likely reside.

Levees have been constructed to protect portions of Butte County including Chico. The Chico Creek-Mud Creek Levee System on the north side of the city protects Chico from the Big Chico Creek north to the levee. The CSU Chico campus north of the Big Chico Creek is located within a designated levee protected zone due to the Chico Creek-Mud Creek Levee.
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.

- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.

- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

- Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is
required for all high hazard dams and is recommended for all significant hazard
dams. Based on these dam failure scenarios listed below, along with the
occurrence of minor spill events (see hazard history below), the planning
committee ranks the extent of the dam failure hazard as Moderate – although
large dams are prevalent in the area, as high-priority critical infrastructure, they
are closely maintained and monitored.

- The California Park Lake is a private lake built by an earthen embankment owned
  by the residential community association. The lake contains 335-acre feet of water.
  Water released from a failure of the dam is expected to enter into the Big Chico
  Creek flowing through the CSU Campus, however, is expected to remain within
  the creek channel. The inundation area does include parts of downtown Chico.

- The Paradise and Magalia Dams both are located on the Butte Creek River, a
  tributary to the Feather River. The river and the inundation zones are both
  immediately south of Chico. Inundation water is not expected to be threat directly
to the campus but may compromise California Highway 99 and access to/from the
  south.

- Shasta Lake is a large reservoir located in Shasta County approximately 80 miles
to the north of Chico. The Shasta Dam is a concrete gravity dam containing
4,661,860-acre feet of water on the Sacramento River system. A failure of Shasta
Dam would be catastrophic for much of the northern Sacramento Valley, but is
expected to remain west of Chico and 2 ½ miles from the campus. Transportation
routes would likely be heavily impacted limiting supplies, emergency resources,
and evacuation capabilities.

- The Oroville Dam was constructed to provide flood protection for the Sacramento
  Valley, hydroelectric power, and to provide storage of domestic and agricultural
  water to the region. The dam is subject to potential seismic activity as known fault
  lines extend near the dam including the Cleveland Hill and Swain Hill faults. The
  Oroville Dam is made up of two separate dams including the main dam and the
  service spillway/emergency spillway. The main dam is an earthen embankment
dam that is the tallest dam in the US at 770 feet tall. Oroville Dam complex
  experienced a potential compromise scenario and utilization of its emergency
spillway and implementation of its emergency action plan in February of 2017. The inundation maps for Oroville Dam indicate water flowing to the south away from Chico but covering transportation corridors from the Sacramento area.

Figure 6-4: Inundation Map
Extent – Levee Failure

Levees are used along numerous flood control and irrigation channels in the Chico area. The southern bank of Mud Creek is lined with a levee protecting the northern half of Chico including most of the campus. The CSU Chico campus lies within a levee flood
protected area. In the event Mud Creek was flowing at elevated levels and a failure of a levee were to occur, the CSU Bakersfield campus would likely experience flood related damages. This specific hazard would substantially alter the ability of the campus to maintain operations as damages would be extensive, the campus community would be heavily affected with the loss of life and homes, access to campus would be limited, and student financial capacity to support ongoing education being diminished. Based on these conditions, the planning committee ranks the extent of the levee failure hazard as **Moderate**.

**History of the Hazard**

California has witnessed only a small number of dam failures over past half century. There have been no occurrences of dam failures in Butte County. However, there have been instances of various levels of dam compromises in Butte County. The following examples did not threaten Chico directly but did result in numerous secondary impacts including the receipt and care of evacuees, community economic disruptions, and road closures.

- 1965, concrete spalled and cracked on the Lost Creek Dam. The dam did not fail and was repaired.
- July 5, 1997, a gate failure occurred on the Cresta Dam. This sent a surge of water down the Feather River into Lake Oroville causing a four-inch rise.
- February 11, 2007, heavy precipitation as a part of the series of powerful 2017 storms raised the Lake Oroville until overflowing the emergency spillways. The main spillway was damaged as a result of the heavy rains. The overflow of the emergency spillway caused extensive erosion and threatened to further undermine and collapse the concrete weir. A collapse did not occur, but the damage was extensive. The threat of collapse resulted in the evacuation of 188,000 people.

California has an extensive network of levees primarily throughout the Central Valley. These levees have been constructed using a variety of methods and often were built decades ago. Statewide, levee failures have occurred more frequently than dam failures. **In Butte County, there have been no instances of levee failure.**

**Potential Impacts of the Hazard**

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation

---

zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood-generated debris

The areas near the CSU Chico campus are mostly out of any dam inundation zone of significance. The portions of the Chico region that would experience the most extensive threat to dam failure would include the western portions of the city in the event of a Shasta Dam failure, downtown areas of Chico from the California Park neighborhood dam, and the extreme southern portions of Chico in the event of a Paradise or Magalia Dam failure. Members of the campus community who reside or are employed in these areas would be most impacted. As a large-scale dam failure would cause wide-spread impacts, the campus may experience evacuees or emergency services requesting the use of campus facilities.

**Levee Failure Impacts**

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community

**Probability of Future Occurrence of the Hazard**

Butte County is determined to be at risk from dam and levee failure in many parts of the county. The location of the CSU Chico remains outside of a dam inundation zone; however, the Inundation Zone for the Paradise and High dams lies immediately south of the Chico city limits. The Inundation Zone for the large Shasta Dam is immediately to the west of the Chico city limits. This demonstrates that the potential exists for future dam related issues in relatively close proximity to the campus. There are no official recurrence intervals that have been calculated for dam or levee failures. The probability of future occurrence for both dam and levee failures is **Unlikely**.

**Vulnerability to the Hazard**

The CSU Chico campus is subject to the effects of flooding resulting from compromised dams and levees. The Shasta, Whiskeytown, and Oroville Dams upstream from the campus presents the potential for catastrophic flooding and damage through large swaths of the Sacramento Valley. The campus is vulnerable to failures of these facilities directly in remote situations and indirectly as transportation routes, utilities, critical infrastructure, and other services supporting the campus would be severely impacted. In the case of dam failure, the amount of time to respond to the needs of the campus community prior to inundation will be limited.

The most significant challenge regarding dam failures is they generally result in catastrophic outcomes. Inundation mapping provides estimates of locations in the path of water released during a failure. Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.
The dam inundation zones remain mostly outside of Chico. However, everyone downstream of the dam and within the inundation zone will be vulnerable to the effects of floods and forces of moving water. The levee systems presenting a threat to Chico exist along Mud Creek north of the city and along extending diversion irrigation channels scattered throughout the region. The distributed placement of levees, many near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including academic buildings, operational support facilities, and campus residence halls will result in numerous displaced individuals. Property damage to campus facilities and equipment below the level of flood waters will likely occur. The lack of flood insurance will cause extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the CSU Chico campus will vary depending on when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to dam or levee failure are $344,244,561. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU Chico.

**Vulnerability Assessment Conclusions**
With the exception of the Oroville incident, occurrence of dam and levee failures have not been historically relevant near the CSU Chico campus, the potential for hazards related to the region’s levees and dams still exist. The presence of earthquake faults in proximity to the Oroville Dam, the county’s largest reservoir, presents a valid danger to the dam structure in the event of an earthquake. The consequences of a dam failure would generate catastrophic results to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.

**Drought**

Description of the Hazard

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the
atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.

- **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - Chico) versus water usage for wildfire abatement or natural resource protection.

**Location of the Hazard**

Drought conditions have been identified in Butte County and the city of Chico where CSU - Chico is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.29

That said, most of drought locations relate to groundwater sources; the water table is receding at the university farm.

---

Extent of the Hazard

Given the historical occurrence of severe drought impacts throughout Butte County (including the planning area) and across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire planning area, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. In addition, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels in California have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. These effects though rare, are issues of concern for the campus over the long term.30

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

</tbody>
</table>

**History of the Hazard**

Although previous occurrence of drought is not identified specifically for the campus, historically, drought has been so prevalent in California that its presence is almost continuous. According to the US Drought Monitor, Time Series data, Butte County has experienced 7 periods of drought from 2000 – 2021.

Figure 6-7: Periods of Drought in Butte County, CA, 2001 – 2021

---

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

Best available data does not identify a timeline of historical occurrences specific to the campus, but the water table at the campus farm is receding, indicating the recent occurrence of drought on campus.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.33

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 6-8: Periods of Drought in State of California, 2001 – 202134

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and (according to the US Drought Monitor, Time Series data) on Butte County which includes the Chico State campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by the UC Davis Center for Watershed Sciences, the 2012 – 2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal.” The report calls the groundwater situation in California “a slow-moving train wreck.” Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and

regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

The most significant potential impact associated with drought across the Chico State campus planning area is a reduction in water availability for the municipal area tied to each campus. In fact, groundwater reductions have resulted in a decreased water table at the campus farm. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of Chico State to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of any agricultural research crops and/or field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. However, the wildfire hazard is analyzed separately in this plan. (See wildfire section).

In reviewing the occurrences of drought for Chico State and Chico, CA, the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to Chico State the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs

such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.\textsuperscript{38}

At present, drought-related damage to campus buildings and infrastructure at Chico State has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for Chico State is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including Chico State. A reduction of electric power generation and water quality deterioration are also potential impact factors.

Table 6-13: Summary of Drought Impacts on Water Resources\textsuperscript{39}

<table>
<thead>

Precipitation | Direct | Warmer winter temperatures will result in a greater percentage of precipitation falling as rain rather than as snow
---|---|---
Groundwater | Indirect | Reduction in snowpack and extended periods of drought are likely to increase dependency on groundwater

Probability of Future Occurrence of the Hazard

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence in the state in any given year. Given that Chico State lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the Chico State campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the Chico State planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2 million acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

---

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.\textsuperscript{41}

**Vulnerability of Populations**

The historical and potential impacts of drought on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the Chico State campus.

**Property Vulnerability**

The historical and potential impacts of drought on property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the Chico State campus.

**Natural Environment Vulnerability**

The historical and potential impacts of drought on the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental

\textsuperscript{41} National Oceanic and Atmospheric Administration National Centers for Environmental Information. *State Climate Summaries: California*. Retrieved 05.04.2021 from: https://statesummaries.ncics.org/chapter/ca/
management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for Chico State’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of Chico and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets and data on tree mortality.
Earthquake

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

Fault Rupture – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

Liquefaction – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.
**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. Chico is located in the northern portion of the Sacramento Valley along the eastern edge at the base of the Sierra Nevada Mountains. In general, fault systems occur to the west and east of Chico. Throughout the valley the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 110 miles west of the CSU Chico campus. In addition to the San Andreas Fault, Butte County is home to or near additional fault systems with the potential to generate strong ground shaking. The Cleveland Hills Fault traverses along the foothills 25 miles southeast of the CSU Chico campus. The Big Bend Fault extends approximately 20 miles in length from Paradise eastward 15 miles east of the CSU Chico campus. The 120-mile-long Bartlett Creek Fault extends from Lake Berryessa to the northwest along the Coastal Range 60 miles west of the CSU Chico campus. The Maacama Fault follows US Highway 101 through Mendocino County 85 miles from the campus. The Mohawk Valley Fault extends in a north-south direction on the east side of the Sierra Nevada Mountains 65 miles to the east.
Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released. Based on the fact that all of Butte County is at moderate risk to seismic activity, but has a minimal history of significant earthquakes resulting in damages, the planning committee ranks the extent of the earthquake hazard as Moderate.
The Richter magnitude scale was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:
Table 6-15: Modified Mercalli Intensity Scale

</tr>
</tbody>
</table>

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.
Given the campus’ relatively far distance from fault systems, the history of minor events and the probability of future events being fairly low for somewhat distant fault lines, the planning committee ranks the extent of the hazard for the campus as **Low**.

### History of the Hazard

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Butte County has a limited history of earthquake activity. The entire area of Butte County is at moderate risk to seismic activity and has a minimal history of significant earthquakes resulting in damages.

---

The August 1, 1975 Oroville Earthquake estimated a Magnitude 5.7 earthquake struck resulting in the greatest amount shaking experienced in Butte County. The earthquake occurred just southeast of Oroville 26 miles to the southeast of Chico. The earthquake resulted in numerous surface ruptures along a 3.8 km zone. Minor structural damage occurred throughout the Oroville area including broken windows, cracked or toppled chimneys, loosened walls, and other structural damages. The shaking was strong enough to felt throughout northern California and western Nevada.

Potential Impacts of the Hazard

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the alluvial soils surrounding the campus presents a moderate potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Chico area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Chico could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake could result in extensive casualties. expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Chico region limiting immediate assistance that the campus may normally expect.

Local impacts to the CSU Chico campus caused by an earthquake could include:

- Damage to nearby refineries and petrol-chemical plants
- Damage and secondary fires to industrial buildings to the east of campus
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway system
- Structural damage to bridges over waterways and flood control channels
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to levees
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the fault systems surrounding Butte County and Chico is included in the following table.

Table 6-17: Major Potentially Active Faults in Proximity to CSU Chico

</tr>
</tbody>
</table>

While seismic activity is not common in Butte County, counties to the west and east are at higher risk for earthquakes. The fault systems described above each reside outside of the county but have the potential to effect Butte County. Based on the earthquake shaking potential in the areas east and west of the Butte County area, the distance from fault systems listed in the above table, the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of Chico sits at the base of river systems that have deposited sediment from the surrounding mountains. In many cases, these sediment-based soils are loose and expose the potential for liquefaction. The majority of Chico has identified a moderate risk of liquefaction including the campus.

The known fault systems generating the threat to Chico generally exist to the east and west of the city but do not cross into the city including the CSU Chico campus. However, the proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected. Campus buildings and equipment

Elements of the vulnerability to a major earthquake on the CSU Bakersfield campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the city. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or

<table>

<td>3%</td>
</tr>
</tbody>
</table>

6-57
equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $344,244,561.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the Chico region and the CSU Chico campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU Chico campus and community.

In the event that a major earthquake was to strike along the fault systems surrounding Chico, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Chico region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency
resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shock continue. These effects are magnified for populations having specific vulnerabilities or access limitations.

**Identified Data Limitations**

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.
**Erosion**

**Description of the Hazard**

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.” Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable.

**Location of the Hazard**

Erosion is a relatively non-spatial hazard that can occur in any location with conducive soil structure and a source of movement such as water or wind. As such, for the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the CSU-Bakersfield campus with erosion-prone characteristics. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover. Streambank and bluff erosion can occur near any riverine area, such as the Big Chico Creek, which flows through the campus, or the Little Chico Creek, which is proximal to the campus. While erosion conditions are known to exist on campus generally, other than the locations identified under History of the Hazard (below) no additional locations have been identified. A comprehensive assessment of erosion conditions/locations campus-wide may be conducted in the future if campus leadership determines it is needed.

**Extent of the Hazard**

If conditions are favorable, erosion is likely to occur. The City of Chico considers the severity of streambank erosion to be limited and present in 10-50% of the city.

Given the occurrence of erosion on campus, the planning committee ranks the extent of this hazard as Moderate.

**History of the Hazard**

Erosion has occurred in the facilities yard on campus and is being exacerbated by a homeless encampment between Nord Avenue and the railroad. There is also an existing

---

bank erosion project in Big Chico Creek west of Nord Avenue, intended to diminish the flow of water.

**Potential Impacts of the Hazard**

Erosion causes instability in soil. During high-intensity rain events, for example, eroded areas will continue to erode, resulting in additional loss of soil and ground stability in the area. This removal of sediment can result in damage to infrastructure, public health, and safety. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled.

In agricultural areas, the erosion of soil degrades the quality of the soil, which can lead to reduced crop yields. At the Paul L. Byrne Memorial University Farm, soil erosion can create significant concerns for agriculture and research. Eroded test plots can negatively impact experiments and tests, resulting in a loss of knowledge and data.

**Probability of Future Occurrence of the Hazard**

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, such as wildfires and flooding, erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the current and potential extent of erosion on campus, the probability of future occurrence is High.

**Vulnerability to the Hazard**

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Chico infrastructure, buildings, and agriculture located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. CSU leadership would consider performing an analysis to identify such at-risk buildings, infrastructure, slopes and soil types in the future.

In the wider Chico community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems, and loss of water quality.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks. Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

**Vulnerability Assessment Conclusions**

While the ability to predict future erosion on the CSU Chico campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left

---

unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Heat**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.49

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.50 As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feels” hotter. The combination of temperature and humidity is known as the heat index.51

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.52 In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.53

**Location of the Hazard**

Extreme heat events are a non-spatial hazard and may occur throughout the Chico State campus.

**Extent of the Hazard**

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the high 80s to mid-90s in the City of Chico. According to data from the National Climatic Data Center (NCDC), the highest daily temperature recorded at the Chico University Farm Station was 114° F on September 14, 1988. Given the historical

51 Ibid.
occurrence of extreme heat events, and that there have been many days when the actual air temperature in Chico reached 100° F or greater, the planning committee ranks the extent of the hazard as **Moderate**.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria.\(^{54}\) In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 6-11 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

Figure 6-11: Methodology for Determining Heat Index

![Figure 6-11: Methodology for Determining Heat Index](attachment:heat_index_methodology.png)

As the heat index rises, so does the potential danger to people and animals. Table xx (following) shows the health hazards associated with extreme heat.

---

</tr>
</tbody>
</table>

**History of the Hazard**

Data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database shows two excessive heat events that have impacted Butte County (in 2017 and 2018), but no excessive heat events that have affected the City of Chico specifically. However, NCDC data indicates that there have been many days when the actual air temperature in Chico reached 100° F or greater.

**Potential Impacts of the Hazard**

Chico State may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

**Probability of Future Occurrence of the Hazard**

There have been two extreme heat events in Butte County within the last four years. In addition, NCDC data indicates that there have been many days when the actual air temperature in Chico reached 100° F or greater. As such, it is **Likely** that the hazard will occur annually.

---

Vulnerability to the Hazard

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.56 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

CSU Chico is aware of the potential for extreme heat events. During the early months of the fall semester, the campus will issue its own heat warnings (in addition to any warning issued by the City of Chico) for students’ safety. When it comes to staff safety, supervisors are reminded of Occupational Safety and Health Administration (OSHA) regulations that protect workers from extreme heat. Under OSHA law, employers must provide workplaces free of known safety hazards, which includes protecting workers from extreme heat, and any employer with workers exposed to high temperatures should establish a heat illness prevention program that includes monitoring workers for signs of illness and providing them with water, rest, and shade.57

In addition, CSU Chico has considered the possibility of opening a cooling center on campus that would be open to students as well as the public.

Therefore, while this is a hazard that the campus may experience with regularity, the campus has ample familiarity with in order to handle the risks and vulnerabilities.

Estimate of Potential Losses

Based on the previous historical occurrences of extreme heat events, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the CSU Chico campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), areas north of Sacramento have warmed approximately 1.5 – 2

degrees on average over the last century, with less rainfall. This may lead to stronger heat events, drought, and an increased risk of wildfires.\textsuperscript{58}

**Cold**

**Description of the Hazard**

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.\textsuperscript{59}

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.\textsuperscript{60} This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underlying tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes.\textsuperscript{61} It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases.\textsuperscript{62} The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6° F. Hypothermia occurs when your body temperature falls below 95° F.\textsuperscript{63} As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is a separate hazard from severe winter storms.

Location of the Hazard

Extreme cold events are a non-spatial hazard and may occur anywhere at the Chico State campus.

Extent of the Hazard

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in the City of Carson are typically in the mid-30s to high 30s. According to data from the National Climatic Data Center (NCDC), the lowest daily temperature recorded in Chico was 12° F on January 22, 1990.

Given that Butte County has had 11 cold/wind chill or frost/freeze events, dating back to 1998, but no extreme cold hazards, the planning committee ranks the extent of the hazard as Low.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30° F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.64

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure 6-12 (following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow). Given the historical and potential occurrence of freezing temperatures, but a low probability of extreme cold, the planning committee ranks the extent of the hazard as Low to Moderate.

In 2011, the National Weather Service introduced an experimental program that issued warnings for extreme cold events, independent of other severe weather warnings. The test areas included North and South Dakota and Minnesota. However, in 2012, after a single season of use, the program was abandoned, based on reports of confusion among test audiences.65

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, Butte County has had 11 cold/wind chill or frost/freeze events, dating back to 1998, but no extreme cold hazards. [Records for this hazard were first recorded in 1996].

Potential Impacts of the Hazard

Should an extreme cold event occur, Chico State might experience impacts due to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

**Probability of Future Occurrence of the Hazard**

The City of Chico has experienced cold/wind chill and freeze/frost events, but has never experienced an extreme cold event. Although the City experiences a wide variance of temperatures, due to the City’s location and its temperate climate, it is **Unlikely** that an extreme heat event will occur annually.

**Vulnerability to the Hazard**

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, extreme cold can kill when the body is pushed beyond its limits. Most danger due to the cold is because the victim has been overexposed to low temperatures. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme cold. The elderly, those with certain preexisting conditions (hypothyroidism, diabetes, and high blood pressure, just to name a few), those with poor blood circulation, and people who are not dressed warmly enough for the cold are generally more vulnerable and are more likely to suffer illness or death as a result.\(^{66}\) This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

CSU Chico is aware of the potential for extreme cold events, and is one of the CSU campuses facing the greatest variance in temperatures. During freeze/frost events, the campus will issue warnings to students and staff about keeping the heat running at a certain temperature in order to protect pipes from freezing and bursting.

**Estimate of Potential Losses**

CSU Chico sponsors a large (three-acre) organic vegetable garden, which grows 50 varieties of vegetables to supply the Community Supported Agriculture (CSA) membership and also regularly provides fresh food to the university’s food pantry. A frost/freeze or extreme cold event during the growing season could negatively impact the harvest. However, the vegetable garden is just a small part of CSU Chico’s 800-acre Paul L. Byrne Memorial University Farm. The farm includes:

---

• 70 acres of almonds, including 30 acres dedicated to an almond variety trial in conjunction with the California Almond Board
• 75 acres of walnuts
• 10 acres of pecans
• 10 acres of olives
• A peach orchard
• Livestock (pigs, cows, sheep)
• Five greenhouses
• An arboretum
• A rose garden

Freeze/frost events are still relatively rare in Chico, but potential losses to the university’s Agricultural Institute could be substantial if the cold event was prolonged. However, based on the previous historical occurrences of extreme cold events, annualized losses are considered unlikely.

Vulnerability Assessment Conclusions

While the ability to predict future extreme cold events at the CSU Chico campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), areas north of Sacramento have warmed approximately 1.5 – 2 degrees on average over the last century, with less rainfall. This may lead to fewer frost/freeze events in the future.67

Identified Data Limitations

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

Flood

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influences human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other feature may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.
Riverine Flooding – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

Localized Flooding – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

Infrastructure Failure – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

Coastal Flooding – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

Atmospheric River

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Location of the Hazard

The Big Chico Creek, Little Chico Creek, and Lindo Channel have been identified as the primary flood sources for the City of Chico including the CSU Chico campus. The Big Chico Creek flows through the campus separating campus buildings and facilities. The Little Chico Creek is located ½ mile to the south of the campus opposite on the opposite side of downtown Chico. The Lindo Channel is a mile to the north of campus opposite of a residential neighborhood. The CSU Bakersfield campus sits entirely within a Zone X (Minimal Flood Hazard Area) designation on the Flood Insurance Rate Map. The Zone X designated areas are subject to inundation by a 0.2-percent annual chance that a flood event will occur.

---

Figure 6-14: Flood Hazard Areas at CSU Chico
Extent of the Hazard

The CSU Chico campus is located in a designated Zone X. The Big Chico Creek flowing through campus is designated as Zone AE but is confined to the boundaries of the creek channel. Portions of downtown Chico to the south of campus are Zone X and Zone AO. Although comprehensive campus-level flood data is not available, given that 12 Federal and State declared flood disasters have occurred in/near the city of Chico from 1982 - present, along with the creek’s AE Zone and related potential impacts, although no flood events have taken place on campus, the planning committee ranks the extent of the flood hazard on campus as Moderate.
In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

Table 6-19: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no BFEs or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised maps in place on Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or base flood elevations are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, base flood elevations derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
<tr>
<td>Zone AH</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.</td>
</tr>
<tr>
<td>Zone AO</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.</td>
</tr>
<tr>
<td>Zone X (shaded)</td>
<td>0.2%</td>
<td>Represents areas between the limits of the 1% annual chance of flooding and 0.2% chance of flooding.</td>
</tr>
</tbody>
</table>
Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain, areas of 1% annual chance sheet flow flooding where average depths are less than 1 foot, areas of 1% annual chance stream flooding where the contributing drainage area is less than 1 square mile, or areas protected from the 1% annual chance flood by levees. No BFE or depths are shown within this zone.

History of the Hazard

Flooding in Chico and the broader Butte County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and numerous fatalities. Though no campus flooding records are reported, the following table (6-25) provides insight into information of past flooding events that are significant to the CSU Chico campus.

Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community
Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

The location of the CSU Chico campus mostly resides outside of any Special Flood Hazard Area. However, the Big Chico Creek (Zone AE) flows through the middle of the campus, and one block to the south of the campus are areas designated as a Special Flood Hazard Area Zone A (1% annual chance for flooding). As such, the potential also exists for flooding due to heavy precipitation.

Based on the above factors, along with some occurrences of flooding near the campus, the probability of future occurrence for flooding is Possible.

Vulnerability to the Hazard

The CSU Chico campus is subject to the effects of limited, small-scale flooding resulting from excessive precipitation, snowmelt, river/levee overflow, or a combination of these. The Big Chico Creek, Little Chico Creek, and Lindo Channel present the greatest potential for flooding and damage on campus and surrounding residential and commercial areas of Chico. The channels and extending irrigation channels that surround the campus have limited storage or volume capacities.

Vulnerability to flooding on the CSU Chico campus will vary depending on when the flood were to occur and on the location of people and/or assets located within any low-lying areas on campus. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

During low probability, severe flood events, some campus buildings and infrastructure in low lying areas, might be vulnerable to large-scale flooding if it reaches the university. Campus utilities and communication capabilities could be impacted by flood waters rendering them disabled. A rare flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls, if located in low lying, flood-prone areas, may have transportation limitations requiring evacuation procedures to be implemented if populated. In such areas, flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.
Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need. Students remaining on campus such as those residing in the residence halls would be particularly vulnerable especially those without access to adequate transportation.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $344,244,561. However due to one portion of the campus being located in levee protected area, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. In addition, the campus’ proximity to the Big Chico Creek, Little Chico Creek, Lino Channel, and Mud Creek in addition to the levees providing a barrier between the campus and the river, presents other hazard risk factors for the campus.

The potential for flooding on the campus and the surrounding area generates the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the campus and the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.
**Hazardous Materials**

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.”

Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

---

71 California Department of Industrial Relations. *Worker Safety and Health During Fire Cleanup.* Retrieved 04.18.2021 from: [https://www.dir.ca.gov/dosh/wildfire/Worker-Health-and-Safety-During-Fire-Cleanup.html](https://www.dir.ca.gov/dosh/wildfire/Worker-Health-and-Safety-During-Fire-Cleanup.html)
- **Safety hazards**: fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations
- **Health hazards**: carbon monoxide ash, soot, and dust; asbestos; hazardous liquids; other hazardous substances; heat illness

**Natural-Technological Incidents (Natechs)**

During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. At larger scales (beyond the campus planning area) hazardous materials are located throughout the city of Chico and Butte County, and reflect different types, configurations and scales dispersed across these geographic areas. Based on the Figure below, Chico State is located adjacent to a hazardous waste site and railroad infrastructure.

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard. However, for the CSU – Chico planning committee, based on the types and levels of hazardous materials on or near the campus (see hazmat mapping), the history of hazmat events on and near the campus, and because the assessment of risk is so complex, it is prudent to rank the extent of the hazard for the CSU – Chico campus as High and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, according to the 2018 CA State Hazard Mitigation Plan, 400 hazardous materials problems are tied to 32 past earthquakes, including more than 495 documented
hazardous materials releases due to the Loma Prieta Earthquake alone (this number excludes innumerable leaks in Pacific Gas & Electric’s natural gas distribution system). That said, it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 2021, a total of 2,096 spill events had occurred so far this year. Such events have occurred in all the cities and/or counties where CSU campuses are located.

With regard to hazmat incidents on the CSU – Chico campus, several chemical spill events have originated on site, and several events (including a chemical polymerization accident) have required response from the Butte County hazmat team. In addition, CSU property purchases for the campus have required on-site chemical remediation.

Potential Impacts of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

In addition to the historical event impacts, the potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – Chico campus.

______________

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak\textsuperscript{77}, which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health.\textsuperscript{78} Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Chico) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

**Probability of Future Occurrence of the Hazard**

The probability of occurrence for a hazmat event on the CSU – Chico campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of

future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is possible because the CSU – Chico campus has experienced several hazmat events requiring hazmat team response. That said, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or changes in the amount of chemicals or exposure will likely increase the probability on campus.

**Vulnerability to the Hazard**

Hazardous materials pose a risk to the CSU – Chico campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: a rail line runs north and south through campus which poses a risk of hazmat release from a rail accident, and poses risks to students who frequently walk across the tracks; a propane tank farm is located adjacent to the campus; and, chemical experiments are conducted on campus, both of which hold potential for chemical release and exposure to staff, students, and the campus environment.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Chico leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

**Estimate of Potential Losses**

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

**Vulnerability Assessment Conclusions**

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Chico) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move
through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Butte County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Chico campus, campus-level risks and vulnerabilities are not discreet or isolated, but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – Chico planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
**Landslide**

**Description of the Hazard**

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure.\(^79\) These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Nino storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow.\(^80\) These landslides may impact lives and properties within the deposition zone and can result in downstream flooding. Post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high earthquake potential. Slope failures are also most likely to occur in areas where they have

---

occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in the Figure below. As seen on the map, CSU – Chico is not located in or near any area susceptible to landslides.

Figure 5-16: Deep-Seated Landslide Susceptibility Surrounding CSU Chico

Extent of the Hazard

Landslides are most likely to occur in the foothills and steep slopes east of Chico, where people and structures are not likely to be significantly exposed to the impacts. However, the indirect impacts of landslides in the region may cover a larger geographical extent. Based on the location of the campus outside the landslide risk area, the planning committee ranks the extent of the hazard as **Low**.

---

History of the Hazard

FEMA has declared seven major disasters in Butte County involving landslides, mudslides, or mud flows since 1983. Five debris flow events were recorded by NOAA in the County from 2017 to 2019. All of these events occurred in the Sierra Nevada mountains to the east. A 2018 debris flow, occurring as a result of heavy rainfall in a burn scar area, blocked cars traveling to Chico on Honey Run Road. The event caused $100,000 of property damage. No landslide events have occurred on the campus.

Potential Impacts of the Hazard

CSU Chico may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is somewhat related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events and fires, landslides may generally occur more often. Historically, landslides have occurred occasionally in the foothills to the east of Chico and therefore are likely to occur in the future. However, given the location of the campus well beyond landslide risk zones, the planning committee ranks the probability of the landslide hazard for the campus as Unlikely. That said, based on the occasional occurrence of landslides to the east, the probability of experiencing secondary effects of a landslide such as loss of power or transportation disruption is Possible.

Vulnerability to the Hazard

The City of Chico considers their vulnerability to landslides to be “medium.”82 There is potential for landslides in the foothill portions of the community. Landslides and mudslides are minimal, except in the burn scar areas in the Upper Bidwell Park region.

82 Butte County, California. Local Hazard Mitigation Plan 2019. Retrieved 02.06/2021 from: http://www.buttecounty.net/oem/mitigationplans
The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. Any population proximal to a landslide when it occurs is vulnerable to its impacts. That said, the campus’ vulnerability is limited to secondary effects of a landslide such as power outage or transportation disruption.

**Estimate of Potential Losses**

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Chico.

**Vulnerability Assessment Conclusions**

Community exposure to landslides varies depending on their physical locations – whether in flat plains or on steep hillsides – and on their dependence on critical infrastructure located in landslide hazard zones.

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**

The ability to predict future landslides at the CSU Chico campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.
Power Outage

Description of the Hazard

Chico State University is located in Butte County on the northeast edge of the Sacramento Valley. The Sierra Nevada mountains, where they lie to the east and south, with Chico’s city limits venturing several miles into the foothills. Chico State is the center point of the college town where the South Campus is densely populated with an overwhelming population of young renters who are mostly students at Chico State.

Most aspects of modern life rely on the near continuous availability of utilities, such as electricity, water, and natural gas. Chico State is a highly populated community within one of the country’s largest suburban layouts. An interruption in the supply or distribution of these services can leave highly populated areas, like Butte County, without electricity or sanitation. These interruptions can produce cascading effects from other hazards, such as a major windstorm, leading to an intentional disruptions of transmission lines due to safety concerns.

A power outage event can interrupt day-to-day operations of the campus, like in-person classes, impede, or limit digital, telephonic, or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center, and close restaurants around campus and outside the campus. Additionally, thousands of Chico State student residents in on-campus housing would also be affected by a power outage on campus and in the area. Additionally, a severe outage to Butte County or the City of Chico would also directly affect the campus and the community.

An electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions:

- Planned: Some disruptions are intentional and can be scheduled based maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.
**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

**Location of the Hazard**

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

**Extent of the Hazard**

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO) which is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities. CAISO is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are as follows:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. That said, only one recorded outage has taken place on campus. As such, the planning committee ranks the extent of the power outage hazard as **Minimal**.
History of the Hazard

Chico State has experienced power outages for various reasons. The university worked with the community’s local electric utility company, PG&E, to restore energy to the campus for its facilities, assets, resident halls, and classrooms. The following are examples of power outage events experienced over the last 10 years:

On December 5, 2020, PG&E experienced a power outage that impacted Chico State. The power outage occurred due to a squirrel that contacted equipment inside of a substation. The incident affected 5,458 students.

Several classes were canceled due to a power outage on April 6, 2015. The outage was caused by an insulator at the Table Mountain Station experiencing a system failure. The power outage resulted in affecting approximately 79,000 customers in Butte County.

Potential Impacts of the Hazard

Instructors, campus residents, staff and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

During a power outage at Chico State buildings on campus cannot continue regular functions at normal levels. Chico State has access to emergency generators on campus that can be utilized to power egress lights and elevators to evacuate buildings in the event of a power outage.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and daily, during
the daytime peak of the diurnal temperature cycle. During future heatwaves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs yearly during the same seasonal periods of variance throughout the calendar year - The City of Chico and the surrounding area experience such outages on a regular basis. Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future. Therefore, the planning committee ranks the probability of future occurrence on campus as **Likely**

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

**Estimate of Potential Losses**

The data provided by Chico State does not report any value for potential losses due to power outage.

**Vulnerability Assessment Conclusions**

The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Chico State University. Safety and operations protocols center on the following “direct impact” set of concerns:

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to, maintain a safe campus environment and visibility during nighttime hours. The vulnerable population, especially students with physical disabilities may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors and locks and lights may impede on a disabled student’s ability to travel and utilize the campus and its structures safely.
The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

**Identified Data Limitations**

Chico State did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. A small portion of Butte County is within the Lassen Volcanic Center ash hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein 2 inches or more of ashfall following an eruption is possible. A portion of Butte County is located within a volcano hazard zone. While CSU Chico does not fall within an estimated ashfall zone, lighter dustings of ash outside of that zone may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.
The dashed lines in Figure 6-17 enclose areas where two inches or more of ashfall are possible. However, it should be noted that hazard maps are dynamic and updated periodically as research adds new information.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

---

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Chico is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Chico.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. Lassen Volcanic Center has a .5 percent chance of eruption in the next thirty years. As such, the annual probability of future occurrence for the campus is ranked by the committee as *Unlikely*.

Vulnerability to the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Chico, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.
Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

CSU Chico is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.
Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- Topography – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.

---

- **Weather** – Weather factors substantially influence the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

### Location of the Hazard

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. Chico is located in the central portion of the Sacramento Valley along the eastern edge at the base of the Northern Sierra Nevada Mountains. In general, areas considered to be within Fire Hazard Severity Zones defined by the Fire and Resource Assessment Program (FRAP) within the California Department of Forestry and Fire Protection (CalFire) occur to the east, west, and north of Chico. These areas surrounding the valley are topographically diverse, contain heavier vegetative fuels, and often have residential development interspersed. The land in the Sacramento Valley where the CSU Chico campus is located, is largely urban, developed, or agricultural. The CSU Chico campus is intersected by the Big Chico Creek.

The CSU Chico campus is located in the western portion of the City of Chico. The area immediately surrounding the campus is predominately developed with residential and commercial land uses. The campus is established in downtown Chico surrounded by developed neighborhoods. Fire Hazard Severity Zones are found 3 miles to the north and east towards the foothills. Immediately bordering the City of Chico are Moderate and High Fire Hazard Severity Zones. Very High Fire Hazard Severity Zones are found further up the hillsides. To the west of the city are agricultural areas with extensive crop and orchard production.
Extent of the Hazard

The area immediately surrounding the CSU Chico campus is not in proximity to high fire hazard zones. The Chico campus has experienced multiple days of poor air quality due to fires burning in Butte County and neighboring counties. However, given that the threat to fire directly spreading onto the campus is minimal, the planning committee ranks the extent of the hazard as Low.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

87 California Department of Forestry and Fire Protection, Fire and Resource Assessment Program, Fire Hazard Severity Zone Viewer. Retrieved 05.05.2021 from: https://egis.fire.ca.gov/FHSZ/
The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 6-22: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel – especially draped fuel – may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 4: Very High Danger (VH)</td>
<td>Fires start very easily and spread at a very fast rate</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is rarely possible after they have been burning more than a few minutes.</td>
</tr>
<tr>
<td>COLOR CODE: Orange</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.

Table 6-23: Air Quality Index for Ozone and Particulate Pollution

<table>
<thead>
<tr>
<th>Daily AQI Color</th>
<th>Levels of Concern</th>
<th>Values of Index</th>
<th>Description of Air Quality</th>
</tr>
</thead>
<tbody>
<tr>
<td>Green</td>
<td>Good</td>
<td>0 to 50</td>
<td>Air quality is satisfactory, and air pollution poses little or no risk.</td>
</tr>
<tr>
<td>Yellow</td>
<td>Moderate</td>
<td>51 to 100</td>
<td>Air quality is acceptable. However, there may be a risk for some people, particularly those who are unusually sensitive to air pollution.</td>
</tr>
<tr>
<td>Orange</td>
<td>Unhealthy for Sensitive Groups</td>
<td>101 to 150</td>
<td>Members of sensitive groups may experience health effects. The general public is less likely to be affected.</td>
</tr>
</tbody>
</table>

Some members of the general public may experience health effects; members of sensitive groups may experience more serious health effects.

Health alert: The risk of health effects is increased for everyone.

Health warning of emergency conditions: everyone is more likely to be affected.

### History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Butte County also has a long history of wildfire activity primarily in the foothills and mountains surrounding the Sacramento Valley. Wildfires occurring in Butte County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damages.

The area immediately surrounding the CSU Chico campus is not in proximity to high fire hazard zones. The Chico campus has experienced multiple days of poor air quality due to fires burning in Butte County and neighboring counties. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Chico. CSU Chico personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

Fire has contributed significantly to Butte County’s hazard and disaster history. Some particular fires that have shaped the way fire plays into preparedness, planning, response, recovery, and mitigation efforts are described in the following.

The June 11, 2006 Humboldt Fire in Butte County east of Chico burned a total of 23,344 acres in moderate to heavy fuels. The fire demonstrated extreme fire behavior during red flag fire warning conditions. The arson caused fire forced the evacuations of 9,000 people, destroyed 87 homes, damaged 7 homes, and destroyed 167 other buildings. The fire was contained after five days and ultimately caused $21 million in damages.

The Butte Lightning Complex ignited on June 21, 2008 due to lightning strikes. At one point there were as many as 27 separate lightning fires burning in the higher elevations of Butte County east of Paradise. Multiple communities were threatened. The three-week long fire burned 59,440 acres, destroyed 202 homes and 11 other buildings, and cost over $85 million.

The Camp Fire is the worst suffered fire in Butte County history. The fire ignited on November 8, 2018 in an area that had been identified as being “the greatest risk to the ridge communities is from an East Wind driven fire that originates above the communities and blows downhill through developed areas.” This is what occurred in November of 2018 leading to the eventual destruction of 64% of structures in the Town of Paradise. Conditions were optimal for intense fire speed and spread, minimal humidity, unusually dry fuels, hot gusty winds, and heavy fuel growth. Roadways leading in and out of the area were only a handful of two-lane highways limiting capacity for

---

evacuations and entry for fire resources. The fire grew rapidly to a final 153,336 acres destroying entire communities. The smoke generated from this fire spread for hundreds of miles and degraded air quality across Northern California. Cities like Chico received evacuees and supported their needs for months. The CSU Chico campus participated in this effort as a community partner. Ultimately, almost 19,000 structures were destroyed, including almost 14,000 residences, 528 businesses were destroyed, significant infrastructure was destroyed including communications systems, and 85 people were killed.

Potential Impacts of the Hazard

The location of the CSU Chico campus surrounded by residential and commercial development mitigates the direct effect that direct flame exposure from wildfire would pose on the campus. There is potential for fire in the urban forest to develop and grass fires to occur in the surrounding fields composed of light and flashy fuels. The threat of these fields to campus structures is minimal.

Potential impacts to the campus community resulting from wildfires include:

- Injuries or loss of life
- Campus property destruction or damage
- Residential property destruction or damage
- Commercial property destruction or damage
- Loss of property contents
- Infrastructure damage
- Damaged or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Damaged or destroyed critical facilities supporting campus emergency support needs
- Loss of community economic base
- Employment losses
- Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Societal and community impacts
- Damage to organizations and facilities providing support services to vulnerable populations
- Greater evacuation challenges for those most vulnerable
Psychological impacts of impacted populations
Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:

- Dangerous levels of air pollution
- Human Health Effects
- Air conditioning systems overwhelmed
- Greater demands on air filtration systems
- Greater demands on healthcare systems

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Butte County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydro-electric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community. Finally, the campus may experience effects of evacuated individuals arriving on campus from other areas as a location of refuge.

Probability of Future Occurrence of the Hazard

The CSU Chico campus is located in an area not considered to have a high wildfire risk. Based on the wildfire threat potential in the area surrounding the CSU Chico campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered Unlikely.

Based on the wildfire threat potential in the area surrounding the Chico region, including the volume of areas in elevated Fire Hazard Severity Zones surrounding the northern Sacramento Valley, the probability of wildfire generated smoke impacts to air quality is considered Likely.

Vulnerability to the Hazard

The CSU Chico campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban/suburban area of Chico. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of Chico and within the agricultural areas surrounding the city. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.
Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

The greater concerns regarding vulnerabilities to wildfire are related to the smoke that fires in the area would produce. The past few summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Sacramento Valley even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Chico students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU Chico campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The risk to wildfire directly impacting the campus is minimal. Costs would be likely be limited to mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.
Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $344,244,561. However due to the campus being located in an urban environment, it is unlikely for fire to cause destructive losses.

Vulnerability Assessment Conclusions

While the occurrence of wildfires has been more frequent in Butte County, historically there have not been wildfire incidents that have caused damages near the CSU Chico campus. The location of the CSU Chico campus surrounded by residential and commercial developed neighborhoods limits the ability for wildfire to threaten the campus. The foothills and mountains surrounding the northern Sacramento Valley host environments that are ideal for the development of wildfire activity. The consequences of fires in these areas would present primary and secondary consequences to the CSU Chico campus and expose vulnerabilities on the campus and to the campus community.

The topography of the valley surrounded by mountains allows for smoke filled air to linger in the Chico area with the potential for unhealthy air quality. Fires in the watersheds of the Feather River and tributaries may damage vegetation stabilizing hillsides and result in increased sediments to be discharged into the river system and reservoirs reducing their capacity and effectiveness. Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. The potential for large-scale wildfires and resulting damage of homes and businesses has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.
Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Severe Weather (Wind, Tornado, Hail, and Lightning)**

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves, unusually cold temperatures, extreme rainfall, and flooding.\(^\text{93}\) According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”\(^\text{94}\)

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

**Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO**

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU Chico.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU Chico), other severe weather phenomena may occur in California at any
time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.\textsuperscript{101}

**Types of Storms in California**

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage.\textsuperscript{102} The SHMP also lists the following types of storms that produce hazardous conditions and potential damage throughout the state of California.\textsuperscript{103} These storms affect (in varying degrees) all CSU campuses, including CSU Chico.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{104} Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.\textsuperscript{105} Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{106} **Severe thunderstorms** are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\textsuperscript{107} \textsuperscript{108}

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.\textsuperscript{109}

\textsuperscript{101} Retrieved on 07.17.2021 from https://wrcc.dri.edu/Climate/narrative_ca.php
\textsuperscript{104} Retrieved on 07.14.2021 from https://www.weather.gov/phi/ThunderstormDefinition
\textsuperscript{107} Retrieved on 07.15.2021 from https://www.noaa.gov/explainers/severe-storms
\textsuperscript{108} Retrieved on 07.15.2021 from https://www.weather.gov/safety/thunderstorm
- **Wind storm**: marked by high wind with little or no precipitation.\(^{110}\)

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\(^{111}\)

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.\(^{112}\)

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.\(^{113}\)

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.\(^{114}\)

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: **wind hazards** (including tornadoes), **hail**, and **lightning**. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

Wind Hazards

Wind is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure. Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.”

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU Chico).

High Winds, Strong Winds, and Thunderstorm Winds

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.

References:

Please note: **Straight-line wind** is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms. However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

**Tornadoes**

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth. This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes. On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.

**Mountain-Valley (Downslope) Wind Systems: Santa Ana, Diablo, and Sundowner Winds.**

**Santa Ana Winds.** A type of wind hazard that is peculiar to Southern California is called a **Santa Ana Wind.** Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico). They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape. (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.127

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and

---

coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can even reach hurricane force ( ≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.128 129 130

**Hail**

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.131 It is roughly round in shape and at least 0.2′ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.132

**Lightning**

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.133

---

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{134} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the CSU Chico campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all CSU Chico campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU Chico reflect those of the surrounding community and County. As a result, all assets and people at CSU Chico are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Chico area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.\textsuperscript{135} First developed in 1805, it is still used today to estimate wind strengths.\textsuperscript{136}

</table>

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.
**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{138}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 6-27: Fujita Tornado Scale (Pre-February 2007)\(^{139}\)

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW**.

### Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms.\textsuperscript{143} \textsuperscript{144} That said, according to the \textit{Glossary of Meteorology} published by the American Meteorological Society (AMS), a thunderstorm is reported as \textit{light, medium, or heavy} according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\textsuperscript{146}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- \textbf{Airmass Thunderstorm}: A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{146}
- \textbf{Frontal Thunderstorm}: An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{147} or
- \textbf{Squall-line Thunderstorm}: An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\textsuperscript{148} \textsuperscript{149}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as \textbf{LOW}.

\textit{History of the Hazard}

\footnotesize

\textsuperscript{143} Retrieved on 07.15.2021 from \url{https://www.noaa.gov/explainers/severe-storms}
\textsuperscript{144} Retrieved on 07.15.2021 from \url{https://www.weather.gov/safety/thunderstorm}
Severe weather hazards have been an annual occurrence in Butte County and on the CSU Chico campus. Historical data for these hazards are presented below.

**Historical Storm Data Collection: NCEI Storm Events Database**

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type. For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events. To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

**Wind Hazards (excluding Tornadoes)**

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Butte County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- **High Wind:** at least 41 events, or approximately 1.62 events per year
- **Strong Wind:** at least 9 events, or approximately 0.36 events per year

155 National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from [https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+Strong+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=BUTTE%3A7&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCAFLORINA](https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28Z%29+Strong+Wind&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=BUTTE%3A7&hailfilter=0.00&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCAFLORINA)
- **Thunderstorm Wind**: at least 12 events, or approximately 0.47 events per year.\\(^{156}\)

- **All Wind Hazard events** (excluding Tornadoes): at least 56 events, or approximately 2.21 events per year.\\(^{157}\) (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Butte County, there have been at least **56** wind hazard events since 1996, excluding tornadoes.\\(^{158}\) That translates to an approximate average historical frequency of occurrence of **2.21** wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 62 events) and simultaneous Database searches of all severe weather hazard events (i.e., 56 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Butte County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\\(^{159}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 56 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

### Historical Wind Hazard Losses for Butte County since 1996

According to the NCEI Storm Events Database, the wind hazard events that Butte County has experienced since 1996 have been costly. There have been 3 deaths and 4 injuries,

and property and crop damage estimates have totaled approximately $17,223,000 and $30,000,000, respectively.¹⁶⁰

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 7 reported events of tornadoes in Butte County, which translates to approximately 0.28 tornado events per year.¹⁶¹ Five (5) tornado reports in Butte County since 1996 have been of tornadoes with a severity rating of F0/EF0, with 1 F1 tornado and 1 EF2 tornado also reported.¹⁶²

**Historical Tornado Hazard Losses for Butte County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Butte County has experienced since 1996 have been costly. While there have been no deaths or injuries reported, property damage estimates have totaled approximately $150,000; no crop damage estimates have been reported.¹⁶³

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been eight (8) reported events of hail in Butte County, which translates to approximately 0.32 events per year.¹⁶⁴ (Note: The NCEI Storm Event Database search results for hail indicate that there has been a total of nine (9) reports of hail since 1996. However, one (1)

entry is for a hail event in San Diego County, hundreds of miles away from Butte County. The origin of this discrepancy is unknown at this time.)

**Historical Hail Hazard Losses for Butte County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Butte County has experienced since 1996 have generated minimal losses. There have been no deaths or injuries, and property damage estimates have totaled approximately $1,000; no crop damage estimates have been reported.165 (Note: The San Diego County hail event that was included erroneously in the search results for hail events in Butte County accounted for all injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been four (4) reported event(s) of lightning in Butte County, which translates to approximately 0.16 lightning events per year.166

**Historical Lightning Hazard Losses for Butte County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Butte County has experienced since 1996 have been costly. While there have been no deaths or injuries, property damage estimates have totaled approximately $136,000; no crop damage estimates have been reported.167

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

Information obtained from the NCEI Storm Events Database indicates that there have been 75 occurrences of the severe weather hazard in Butte County. This translates to 2.96 severe weather hazard occurrences per year.\(^{168}\)

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 82 events) and simultaneous Database searches of all severe weather hazard events (i.e., 75 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., “Thunderstorm Wind/Hail” or “Hail/Tornado,” and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Butte County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.\(^{169}\) When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 75 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Butte County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Butte County has experienced since 1996 have been costly. There have been 3 deaths and 4 injuries, and property and crop damage estimates have totaled approximately $17,510,000 and $30,000,000, respectively.\(^{170}\) However, it is important to note that for all Butte County severe weather hazard events recorded on the Storm Events Database, all deaths, injuries, and crop losses, and approximately 98.4% of all property losses, have been caused by wind hazard events alone.

**Wind Hazards Not Included in the NCEI Storm Events Database**

*Santa Ana Winds*

Santa Ana wind events occur at least twice per month from October through April.\(^{171}\) From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting

up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.\textsuperscript{172} \textsuperscript{173}

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Figure 6-20: Mean Annual Frequency of Santa Ana Wind events (1948-2012)\textsuperscript{174} \textsuperscript{175}

\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure620.png}
\caption{Mean Annual Frequency of Santa Ana Wind events (1948-2012)}
\end{figure}

**Diablo Winds**

Diablo wind events occur approximately **2.5 events per year.** These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^{176}\)

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\(^ {177}\)

Figure 6-21: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\(^ {178}\)

---

**Sundowner Winds**

Strong sundowner wind events occur approximately **2-3 times per year.** These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\(^ {179}\)

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within CSU Chico campus areas are at risk from the effects of the severe weather hazard.

Wind Hazards (Including Tornadoes)

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during a hazardous wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU
Chico campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

According to the 2019 Butte County Local Hazard Mitigation Plan (LHMP), wind hazards (including tornadoes) are considered to be medium significance, and therefore to have a moderate potential impact on both the County and (by extension) CSU Chico.\textsuperscript{180}

\textit{Hail}

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

According to the 2019 Butte County Local Hazard Mitigation Plan (LHMP), hail hazards are considered to be medium significance, and therefore to have a moderate potential impact on both the County and (by extension) CSU Chico.\textsuperscript{181}

\textit{Lightning}

Lightning strikes the United States about 20-25 million times a year.\textsuperscript{182} Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.\textsuperscript{183} Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.\textsuperscript{184} (Commercial claim payouts for lightning losses for the U.S. were not available.)

\end{itemize}
According to the 2019 Butte County Local Hazard Mitigation Plan (LHMP), lightning hazards are considered to be of medium significance, and therefore to have a moderate potential impact on both the County and (by extension) CSU Chico.\textsuperscript{185}

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. The 2019 Butte County Local Hazard Mitigation Plan (LHMP) states that there is a near 100\% chance that three (3) of the severe weather hazards profiled above for Butte County (i.e., wind, hail and lightning) will occur in the future, while there is between a 10\% and 100\% chance that the tornado hazard will occur in the future.\textsuperscript{186} Also, according to the NCEI Storm Events Database, some of these same severe weather hazards have occurred in Butte County at least once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Chico campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the CSU Chico campus reflect those of the surrounding community and County identified in the Tables below.

Based on the data available from both the 2019 Butte County Local Hazard Mitigation Plan (LHMP) and the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU Chico campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU Chico is HIGHLY LIKELY. See Table 6-XX for probabilities of future occurrence for component severe weather hazards for Butte County and the CSU Chico campus.

Table 6-32: Severe Weather Hazard Probabilities of Future Occurrence for Butte County and CSU Chico

Vulnerability to the Hazard

People, structures, and assets on the CSU Chico campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The CSU Chico campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.

Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire CSU Chico campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within the CSU Chico campus are at risk from severe weather. There are approximately 94 buildings on the campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazards are $344,244,561 for 66 buildings, and are unknown for the remaining 28 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is not currently available, though CSU leadership may pursue such data in the future.
The population at the CSU Chico campus varies throughout the day. As of Fall, 2019, CSU Chico had 11,199 students and 1,277 faculty and staff; all are at risk from severe weather events, with 12,476 being directly vulnerable in this scenario.187 188

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to the CSU Chico campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU Chico.

It is evident that the CSU Chico campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.

6.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population groups needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Chico campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
Table 6-33: High level summary of campus populations of concern

<table>
<thead>
<tr>
<th>Question</th>

<td>N/A</td>
</tr>
<tr>
<td>Which population groups have little/limited support networks if impacted by an event?</td>
<td>First generation students from socially and economically disadvantaged households</td>
</tr>
</tbody>
</table>

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (AFN), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as *Very High, High, Medium, Low*
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as *Yes, No, In Progress, NA*

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees,
the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Surveys go out to monitor hunger issues.
- Recruiting Hispanic populations, African American populations in the urban areas, and first-generation students from low socio eco backgrounds; having lot of conversations on programs specifically to help support these students, especially those that don’t have cars and are a long way from home; how to support and give community for them to stay local.
- Student health director is pandemic manager in EOC.
- Need for more WIFI / access to high-speed internet. Plans to work on that.
• Communications is in English only. This is a concern for the Hmong are a growing population on the staff and this may be an issue to do outreach in an event, particularly a wildfire.

• For the international students/immigrants/immigration status, they integrate the office that supports them into the emergency, using State Dept. protocols.

• CHICO students come from a long way away—if they close the university and needed to evacuate, there is a concern regarding asking students to go home and then being able to provide a support network to get them and when to tell them to come back. Have MOUs with bus contractors; have three 40 passenger buses, now working with school districts such as Tahama County to move them to an evacuation site close by.

• Have a planning problem with residence halls HVAC – not as safe as a sanctuary as want it to be for the air quality to be good enough to keep the residents there.

• Huge impact on campus with the more extreme weather with dry spells, rainstorms, and megafires.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.

**Communicable Diseases**

*TBD*

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods.\(^{189}\) Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states.\(^{190}\) Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to

drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.¹⁹¹

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and

decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Extreme Temps**

People susceptible to respiratory ailments (asthma, lower and upper respiratory disease) disproportionately suffer from the effects of fire, smoke, air pollutions, allergens, heat and PSPS. Those with limited income or without resources are affected disproportionately due to the inability to provide safe shelter, air conditioning, cooling, air purification, medical care, and quality foods, and are also least able to obtain information related to climate risks and adaptation strategies.

**Heat**

Heatstroke, cardiovascular disease, respiratory disease and cerebrovascular disease are related to extreme heat events. Increased number of heat waves creates heat-related physical stress on populations and is exacerbated in the metropolitan areas where greater amounts of heat-absorbing surfaces (e.g., asphalt and concrete) trap heat and emit higher temperatures throughout the night.

The heat also extends the geographic range and the distribution of disease-carrying insects and pests. Health professionals are concerned that California’s warming climate will allow species to acclimate. Such vectors include such pests as ticks that carry Lyme disease, and mosquitos that transmit Zika, dengue fever, West Nile, plague and tularemia. Some others, such as chikungunya, Chagas disease, and Rift Valley fever virus, are threats as well.

Some communities of color and some low-income, homeless, and immigrant populations are more exposed to heat waves, as these groups often reside in urban areas affected by heat island effects. In addition, these populations are likely to have limited adaptive capacity due to a lack of adequately insulated housing, inability to afford or to use air conditioning, inadequate access to public shelters such as cooling centers, and inadequate access to both routine and emergency health care. These social, economic, and health risk factors give rise to the observed increase in deaths and disease from extreme heat in some immigrant and impoverished communities.

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down. In extreme causes, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.

When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has
been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result.

This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately. Distributional implications of impacts, and even less on distributional implications of adaptation actions.” 192

**Flood**

Risk from floods relates to community risk, exposure and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities. The exposure of humans to floods continues to increase, driven by changes in hydrology and land use. The adverse impacts on socially vulnerable populations are amplified because a disproportionately high number live in flood-prone areas. Research has shown that places of social vulnerabilities are places characterized by housing and racial disparities, such as mobile home parks, structural fragility and poverty, and higher percentages of populations such as Black and Native Americans, and others with shared histories of discrimination, marginalization and exclusion. 193

Health impacts from flooding are well recognized due to the extensive history of flooding in California and around the nation. The impacts range from waterborne illnesses from contaminated waters, respiratory illnesses that impact the lungs, throat, and airways from airborne particles, mold on flooded buildings that can trigger asthma, allergies and other illnesses—all which are particularly impactful to older, younger and individuals with pre-existing health condition. Foodborne illnesses can increase if there are issues with power outages or sewer overflows. Individuals with increased mental health concerns can be impacted by the stress or anxiety from the impacts of the flood. Poor quality housing can

---

increase vulnerability to many flood risks, including flood inundation, power outages, mold growth, rodent vectors, and serious health impacts. For those with limited finances, flood inundation and impacts to infrastructure or farmlands may lead to extensive income losses.

The poorest residents suffer disproportionately to flood situations, especially those who have been less able to fund homeowner’s insurance to protect against flood losses. Loss of life is not unusual in flooding situations, as is loss of property, livestock, pets, workplaces, and tourist industries. There is a strong interrelationship between water events and other hazards. Flooding, storms and water quality are related to each other. Drought conditions can exacerbate floods as the surface soils are hardened and not as ready to allow surface water absorption. Extreme heat events can cause snowmelt, inundating waterways and causing flood and water quality issues. Flooding and storm events can have impacts on public health, environmental health, agricultural heath and economic system health. Mental health issues are reported for all people who have experience flood losses, including anxiety, fear, anger, anger, sadness and grief. 194 Additionally, waterborne disease outbreaks are reported weeks after the flood events. Mold contamination leads to indoor air issues. Damp indoor environments lead to increased prevalence of asthma, and also upper and lower respiratory symptoms.

These issues may influence the diverse CSU populations, both on and off campus, in a number of ways long after a flood event, or the related hazards impacts, has concluded.

**Hazardous Materials**

The severity of a hazardous materials release depends upon the type of material released, the amount of the release, and the proximity to populations or environmentally sensitive areas such as wetlands or waterways. The release of materials can lead to injuries or evacuation of nearby residents. Wind direction at the time of the release can also have a bearing on the severity (as well as the location and extent) of a hazardous materials release.

The primary threat from the hazardous materials incident hazard is to the structures located along transmission lines and transportation routes or near facilities that use or store hazardous materials. Minor incidents would likely cause no damage and little disruption, assuming they could be contained quickly. Major incidents could have fatal and disastrous consequences. The severity of a hazardous material release relates primarily to its impact on human safety and welfare and on the threat to the environment. Threats to human safety and welfare include:

- Poisoning of water or food sources and/or supply

---

- Presence of toxic fumes or explosive conditions
- Damage to personal property
- Need for the evacuation of people
- Interference with public or commercial transportation

Environmental risks are not uniformly distributed across groups of people. Age, poverty, and minority status place some groups at a disproportionately high risk for environmental disease. Poor access to health information and health care means less health promotion, less risk avoidance, a less healthy diet, and more adverse conditions that increase susceptibility to exposure. Delayed recognition of exposure, diagnosis, and treatment allows effects to accumulate.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children.

---

195 [https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/](https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3222496/)

Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.\textsuperscript{199}

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.\textsuperscript{200}

**Hazard Mitigation and Emergency Management Planning**

The goal of this high-level assessment is to provide a starting point to encourage further exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

7.1 University Profile

University History

California State University, Dominguez Hills (CSU Dominguez Hills) was founded in 1960. The need for a campus in the South Bay region of Los Angeles County became apparent in response to a rising population in the 1950s, influenced by the growth of families of World War II veterans, and by emerging aerospace and defense industries. The California State Legislature authorized the establishment of the “South Bay State College” and Governor Edmund G. (Pat) Brown signed it into law on April 29, 1960. The originally designated location of the campus was to be in Palos Verdes, CA. However, the campus site was moved to the Dominguez Hills section of unincorporated (now Carson, CA) within Los Angeles County due to both the rapidly rising land costs in Palos Verdes and the recognized need by State legislators to provide higher education opportunities for the underserved minority populations of South Los Angeles. Today, CSU Dominguex Hills is a federally recognized Hispanic-Serving Institution (HSI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The University Planning Council (UPC) is comprised of provosts/vice-presidents and high-level campus executives on campus who serve in an advisory capacity to the president. The UPC oversees and reviews the implementation of the university’s strategic plan and provides status reports to the president on a bi-annual basis.

University Mission

“We provide education, scholarship and service that are, by design, accessible and transformative. We welcome students who seek academic achievement, personal fulfillment, and preparation for the work of today and tomorrow.”

CSU Dominguez Hills highlight seven core values fundamental to their success; Accountability, Collaboration, Continuous Learning, Rigorous Standards, Proactive Partnerships, Respect and Responsiveness. Additionally, CSU Dominguex Hills embraces the notion of being a campus community and gathering place for the community as a whole.
University Location
The 346-acre CSU Dominguez Hills campus is located in the South Bay region of Los Angeles County, in the City of Carson, CA (population 95,324). The campus is approximately 15 miles south of Downtown Los Angeles.

University Population
Typically, enrollment as CSU Dominguez Hills exceeds 17,000 students. CSU Dominguez Hills prides itself in its diverse campus community. CSU Dominguez Hills is ranked among the nation’s top universities for diversity, accessibility, and affordability. CSU Dominguez Hills’ inclusivity and commitment to diversity has resulted in impressive diverse populations. Nearly 63% of the campus undergraduate population is female, as is 73% of the graduate population. Latino students make up 60.3% of CSU Dominguez Hills students, with African-American students making up the second most population with 14.5%. The majority of students at CSU Dominguez Hills are first generation college students (43%).

7.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and priorities appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the estimate.
**Requirement §201.6(c)(2)(ii)(C):** [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

**Requirement §201.6(c)(2)(iii):** For multi-jurisdictional plans, the risk assessment must assess each jurisdiction’s risks where they vary from the risks facing the entire planning area.

### 7.3 Hazard Identification and Risk Assessment

**Overview of California State University, Dominguez Hills History of Hazards**

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

**Hazard Identification**

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s *How-To Series*, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered XX hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in the table below.

<table>

</tbody>
</table>

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

- **Highly Likely** - 76%-100% that the hazard would occur annually.
- **Likely** - 50%-75% that the hazard would occur annually.
- **Possible** - 11%-49% that the hazard would occur annually.
- **Unlikely** - 0%-10% that the hazard would occur each annually.

**Communicable Disease**

Description of the Hazard
Communicable diseases are illnesses that occur due to infectious agents or their toxic products, and are infectious due to their potential of transmission from one person or species to another by a replicating agent. They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions. The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.

Some ways in which communicable diseases spread are by:

- Travel through the air, such as tuberculosis, measles, or COVID-19;
- Physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- Contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and,
- Bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague).

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 7-2 below.)

(Source: Interviews with CSU campus staff at CSU campuses and at CSU Chancellor’s Office.)

**Descriptions of Identified Communicable Disease Hazard at CSU Dominguez Hills**

CSU Dominguez Hills (CSUDH) has identified one (1) communicable disease hazard that has had the greatest impact on campus – COVID-19. The following is a brief description of the communicable disease hazard at CSUDH.

**COVID-19 (SARS-CoV-2)**

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**. The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.

Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet,
The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.\(^5\)

Location of the Hazard

Communicable diseases have the potential to affect the entire CSU Dominguez Hills planning area equally. As a result, the communicable disease hazard can be found at the CSU Dominguez Hills campus located in Carson, CA (Los Angeles County). Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) CSU Dominguez Hills are at risk of exposure to the communicable disease hazard.\(^6\)

CSU Student Housing Locations and Populations

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For CSU – Dominguez Hills, approximately 5% of its 17,027 enrolled students or 851 students reside in student housing.

### Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard.

Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

Figure 7-1 describes the different BSLs, and provides examples of communicable diseases that would typically fall in to these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.
The Extent of CSU Dominguez Hills Communicable Disease Hazards Except COVID-19:

Besides COVID-19, there was no information provided on other communicable disease hazards on campus.

The Extent of CSU Dominguez Hills COVID-19 Communicable Disease Hazard:

As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.11

History of the Hazard

Over an approximately one-year period, from mid-March, 2020 to March 23, 2021, there were a reported 99 cases of COVID-19 at CSU Dominguez Hills. CSU-campus-specific COVID-19 case data for CSU Dominguez Hills can be found in the “History of the Hazard” section below.

Most communicable disease data are maintained by at the state and at the county levels, and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level

case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 7-5 and 7-6 show campus-level and County-level COVID-19 Case data for CSU Dominguez Hills. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system, including the CSU – Dominguez Hills campus. The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU – Dominguez Hills students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic, and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU – Dominguez Hills) vary both by level of containment (BSL) (described previously) and by

level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 7-7: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g., Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms)</td>
</tr>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
</tr>
</tbody>
</table>

Table 7-8 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3

---

category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.
Table 7-10 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 7-9: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>

<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s system-wide probability ranking (below) reflects the ranking at the individual CSU campus level unless noted otherwise.

### Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the CSU – Dominguez Hills campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall 2019, the CSU System had 480,541 students and 53,763 faculty and staff.)

Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree in the current COVID-19 pandemic on the Dominguez Hills campus.

### Estimate of Potential Losses

**COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities**

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU – Dominguez Hills) are at risk of developing an extreme

---

17 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx
18 The California State University. Employee Head Count by Campus. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/faculty-staff/employee-profile/csu-workforce/Pages/employee-headcount-by-campus.aspx
incidence of COVID-19, and may become “super-spreaders” for adjacent communities.\textsuperscript{19} The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

**Economic Impact of COVID-19 Pandemic on CSU Financial Health**

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. (See Table 7-12 below for the economic impact to the CSU – Dominguez Hills campus).

Several CSU campuses saw refund losses surpass $10 million.

Table 7-11: CSU COVID-19 Cost Tracking Showing Revenue Refund Losses and Increased Costs\textsuperscript{20}

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 7-13) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems. Table 7-14 shows the “10% outbreak scenario” projections both for the CSU – Dominguez Hills campus and for the entire CSU system.

*Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).*

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system including CSU – Dominguez Hills. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.

**Identified Data Limitations**
There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

- Data regarding infection rates at the campus level and for specific populations;
- Data regarding communicable disease case numbers and outcomes, by CSU campus;
- Data regarding projected population changes;
- Data regarding absenteeism; and
- Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).
**Dam and Levee Failure**

Description of the Hazard

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtoppings to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

---

Location of the Hazard

Los Angeles County is home to a variety of flood control facilities and levee systems mostly along the base of the various mountains and hills throughout the county. Levees have been constructed along numerous flood control channels providing community protection. The CSU Dominguez Hills campus is in general proximity to dams upstream along the Los Angeles River and Rio Hondo systems in addition to flood control channels lined with levees.

There are a number of dam facilities along the base of the San Gabriel Mountains and along the river systems extending from the mountains. The larger facilities include the San Gabriel Dam, Morris Dam, Santa Fe Dam, and Whittier Narrows. Each of these facilities regulate water flow along the San Gabriel River and Rio Hondo systems. The CSU Dominguez Hills campus lies outside of dam inundation zones for these facilities.

The Los Angeles River drains the San Gabriel Mountains and much of the Los Angeles Basin south towards Long Beach. A number of flood control systems feed into the Los Angeles River. The length of the Los Angeles River from downtown Los Angeles to the outlet into the ocean is a large concrete lined channel. The channel is located almost 3 miles east of the CSU Dominguez Hills campus, is separated from the campus by additional flood control channels, and is lower in elevation than the campus.

The Dominguez Channel is a flood control and drainage channel ¾ mile southwest of the campus that drains much of the urban water collection of the South Bay communities. The channel feeds into the Pacific Ocean at the Port of Los Angeles before extending 15 miles from Hawthorne and Inglewood. The Dominguez Channel is a concrete lined flood control channel fed by additional channels above the campus. The CSU Dominguez Hills campus is situated slightly higher in elevation from the Dominguez Channel and is outside of the levee protected zone.

The Compton Creek is an additional flood control channel that is located approximately 2 miles east of the campus. The 9-mile channel feeds into the Los Angeles River and ultimately into the Pacific Ocean at Long Beach. The channel drains the south Los Angeles and Compton areas. The CSU Dominguez Hills campus is situated slightly higher in elevation from the Compton Creek and is outside of the levee protected zone.
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

- **High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.
- **Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.
- **Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.
Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

The CSU Dominguez Hills campus lies outside of the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the CSU Dominguez Hills campus is expected to remain out of the inundation area. The inundation area is expected to spread water in areas upstream from the campus and remain within the flood control channels in proximity to the campus. However, there are multiple transportation corridors that lie within the dam inundation zones that could compromise transportation routes and areas the campus community reside or work. For these reasons, the planning committee ranks the extent of the hazard as **Low**.

---

7-28
Extent – Levee Failure

Levees are used along numerous flood control channels and other waterways including the Los Angeles River, Dominguez Channel, and Compton Creek. The CSU Dominguez Hills campus lies outside of the levee flood protected area. In the event any of these channels were flowing at elevated levels and a failure of a levee were to occur, the community surrounding the campus would likely experience flood related damages. This specific hazard could alter the ability of the campus to maintain operations. For these reasons, the planning committee ranks the extent of the hazard as Low.

History of the Hazard

There are no records of dam or levee failures in areas that present a threat to the CSU Dominguez Hills campus. Los Angeles County has experienced the following dam failures:

28 California Department of Water Resources. Dam Breach Inundation Map Publisher. Retrieved 04.08.2021 from: https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2

Potential Impacts of the Hazard

Dam Failure Impacts - Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would
vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

**Probability of Future Occurrence of the Hazard**

Los Angeles County is determined to be at risk from dam and levee failure in many parts of the county. The location of the CSU Dominguez Hills campus downstream from the Santa Fe Springs Dam and other flood control facilities along the Los Angeles River and Rio Hondo demonstrates that the potential exists for future dam related issues. However, the distance from the river channel provides an additional mitigating factor. The City of Carson including the CSU Dominguez Hills campus resides outside of known dam inundation zones. Levees protecting flood control channels are located 2 miles east and ¾ of a mile west of the campus. However, the campus remains outside of levee protected zones. There are no official recurrence intervals that have been calculated for dam or levee failures.

The probability of future occurrence for both dam and levee failures is **Unlikely**.

**Vulnerability to the Hazard**

Given High Priority dam monitoring and maintenance practices in place, a catastrophic dam or levee failure is highly unlikely. In addition, the campus does not lie within an inundation zone. However, in the unlikely event of a catastrophic failure, the effects of flooding from compromised dams and levees on campus would most likely be limited to
indirect or secondary effects in terms of disruption to regional transportation networks and services, and the amount of time to respond to the needs of the campus community prior to inundation will be limited.

Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in the vulnerability of numerous displaced individuals and households. The lack of flood insurance will cause additional extreme financial burdens on those affected.

Vulnerability to a dam or levee failure on the CSU Dominguez Hills campus will vary depending on when the failure was to occur. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to dam or levee failure are $142,163,477. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU Dominguez Hills.
Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the CSU Dominguez Hills campus, the potential for hazards related to the region’s levees and dams still exist. Additionally, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a high priority dam’s total failure, the consequences of a dam failure would generate catastrophic results to downstream communities. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation.
**Drought**

**Description of the Hazard**

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

- **Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

- **Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

- **Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.
• **Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.

The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - Dominguez Hills) versus water usage for wildfire abatement or natural resource protection.

### Location of the Hazard

Drought conditions have been identified in Los Angeles County and the city of Carson) where CSU - Dominguez Hills is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.29

### Extent of the Hazard

Given the historical occurrence of severe drought impacts throughout Los Angeles County (which encompasses the planning area) and across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. In addition, although drought affects the entire planning area, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities, historically impacted by drought within each jurisdiction. In addition, land subsidence has occurred and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels in California have been measured up to 30-feet with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. These concerns should be considered applicable to the campus over the long term.30

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the

U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

Table 7-16: Impacts of Drought Levels as Determined by US Drought Monitor\textsuperscript{31}

<table>
<thead>
<tr>
<th>Category</th>
<th>Impact</th>
</tr>
</thead>
</table>
| D0       | Soil is dry; irrigation delivery begins early  
          | Dryland crop germination is stunted  
          | Active fire season begins  
          | Winter resort visitation is low; snowpack is minimal |
| D1       | Dryland pasture growth is stunted; producers give supplemental feed to cattle  
          | Landscaping and gardens need irrigation earlier; wildlife patterns begin to change  
          | Stock ponds and creeks are lower than usual |
| D2       | Grazing land is inadequate  
          | Producers increase water efficiency methods and drought-resistant crops  
          | Fire season is longer, with high burn intensity, dry fuels, and large fire spatial extent; more fire crews are on staff  
          | Wine country tourism increases; lake- and river-based tourism declines; boat ramps close  
          | Trees are stressed; plants increase reproductive mechanisms; wildlife diseases increase  
          | Water temperature increases; programs to divert water to protect fish begin  
          | River flows decrease; reservoir levels are low and banks are exposed |
| D3       | Livestock need expensive supplemental feed, cattle and horses are sold; little pasture remains, producers find it difficult to maintain organic meat requirements  
          | Fruit trees bud early; producers begin irrigating in the winter  
          | Federal water is not adequate to meet irrigation contracts; extracting supplemental groundwater is expensive  
          | Dairy operations close  
          | Marijuana growers illegally tap water out of rivers |

</tbody>
</table>

History of the Hazard
Historically, drought has been so prevalent in California that its presence is almost continuous, including the region and the Los Angeles municipal area surrounding the CSU - Dominguez Hills footprint. That said, no campus data for drought occurrence at the campus level is available.

Figure 7-4: Periods of Drought in LA County, 2000 – 2020

According to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions

---

34 National Drought Mitigation Center, University of Nebraska. *Drought Impact Reporter*. Retrieved 05.01.2021 from: https://droughtreporter.unl.edu/map/
have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Figure 7-5: Periods of Drought in the State of California, 2001 – 2021

![California Percent Area](https://droughtmonitor.unl.edu/Data/Timeseries.aspx)

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and (according to US Drought Monitor, Time Series data), on Los Angeles County which surrounds the CSU - Dominguez Hills campus planning area:

**2012 – 2017** – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2012-2017 period of the California drought cost the state's agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion. The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal.” The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has

---

contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.38

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

Though no campus impacts have been recorded, the most significant potential impact associated with drought across the CSU - Dominguez Hills campus planning area is a potential reduction in water availability for the municipal area tied to campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - Dominguez Hills to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of any agricultural research crops and/or field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such.39 However, the wildfire hazard is analyzed separately in this plan. (See Section X for coverage of the wildfire hazard).

In reviewing the occurrences of drought for Los Angeles County (where the CSU - Dominguez Hills is located), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2012-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - Dominguez Hills, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the campuses. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus=located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is

currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.40

At present, drought related damage to campus buildings and infrastructure at CSU - Dominguez Hills has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - Dominguez Hills is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - Dominguez Hills. A reduction of electric power generation and water quality deterioration are also potential impact factors.

</table>

### Probability of Future Occurrence of the Hazard

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence in the state in any given year. Given that CSU - Dominguez Hills lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

### Vulnerability to the Hazard

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - Dominguez Hills campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.
As such, the state and the CSU - Dominguez Hills planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2 million acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses. In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.

Vulnerability of Populations

Drought vulnerabilities for California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the CSU - Dominguez Hills campus.

Property Vulnerability

The historical and potential impacts of drought on property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the CSU - Dominguez Hills campus.

Natural Environment Vulnerability

The historical and potential impacts of drought on the natural environment are widespread throughout public and private lands within the state, including tree mortality,

impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerabilities throughout California is water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for CSU - Dominguez Hills’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the city and county of Los Angeles, and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**
Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.

**Earthquake**

Description of the Hazard

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other
structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

Subsidence - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

Location of the Hazard

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU Dominguez Hills is located in the southern portion of the Los Angeles Basin. In general, fault systems surround and traverse through Los Angeles and Orange Counties including the area of CSU Dominguez Hills. Throughout the basin the ground is saturated with sediment eroded from the mountains and foothills via multiple stream and river channels and resulting in liquefaction zones scattered across the region.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 50-60 miles northeast of the CSU Dominguez Hills campus. In addition to the San Andreas Fault, Los Angeles County is home to or near additional fault systems with the potential to generate strong ground shaking. The Newport-Inglewood Fault traverses south to north paralleling the Orange County coastline extending within ½ mile of the CSU Dominguez Hills campus. The Palos Verdes Fault crosses the Palos Verdes Peninsula approximately 6 miles southeast of the campus. The 40-mile-long Compton Fault parallels the Palos Verdes Fault in a southeast to northwest direction 5 miles southeast of the CSU Dominguez Hills campus. The Whittier-Elsinore Fault extends from the eastern base of the Santa Ana Mountains and western base of the Puente Hills 16 miles to the northeast of the campus. There are numerous additional faults in the area on all sides of the campus.
Figure 7-6A: Fault Lines Through CSU Dominguez Hills
Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale (Table 7-19 below) was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example,
indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

</tr>
</tbody>
</table>

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate
of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.

Based on the location of the campus at the end of a fault line, the earthquake shaking potential in the Los Angeles Basin, the proximity to the above listed fault systems, the probability of seismic ground shaking generating damage, the planning committee ranks the extent of the hazard as Moderate.

History of the Hazard

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Los Angeles County also has a long history of earthquake activity. The entire area of Los Angeles County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The January 9, 1994 Northridge Earthquake became the costliest seismic event in California history. The earthquake caused extensive damage to structures, the transportation infrastructure, utility systems, water storage, communications, and critical facilities. This level of damage due to the fault that ruptured was directly underneath a densely populated urban area. The Northridge Earthquake was found to raise the nearby mountains by as much as 70 centimeters. The earthquake was provided a federal disaster declaration (DR-1008).

The October 1, 1987 Whittier Narrows Earthquake shook a large part of southern California. The earthquake caused $358 million in damages, especially in the Alhambra, Pasadena, and Whittier areas. The earthquake resulted in extensive infrastructure damages, multiple injuries, and 8 fatalities. The earthquake was provided a federal disaster declaration (DR-799).

The February 9, 1971 Magnitude 6.5 San Fernando Earthquake struck the San Fernando Valley in Los Angeles just after 6am. The intense shaking caused the collapse of freeway overpasses, hospitals, and other infrastructure. It damaged thousands of homes and businesses, a reservoir, and critical infrastructure. 65 people were killed and 2,000 more were injured. The shaking was felt for 300 miles including in Las Vegas, Nevada. The earthquake was provided a federal disaster declaration (DR-299).

The March 10, 1933 Long Beach Earthquake registered at a Magnitude 6.4 occurred along the Newport-Inglewood Fault. The earthquake resulted in over $50 million in damages, 500 injuries, and 120 fatalities. Unreinforced masonry structures were the source of most of the casualties. 70 schools were destroyed and 120 were damaged. This earthquake

---

promoted statewide standards in building design and construction for schools and other structures to better withstand seismic events.

**Potential Impacts of the Hazard**

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the Los Angeles area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Carson could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Carson could result in extensive casualties, expansive structural damages, panic, widespread utility outages, communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Los Angeles County and Orange County region limiting immediate assistance that the campus may normally expect.

Local impacts to CSU Dominguez Hills campus caused by an earthquake could include:

- Damage to nearby refineries and petrol-chemical plants
- Damage and secondary fires to industrial buildings to the east of campus
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway system
- Structural damage to bridges over waterways and flood control channels
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to Dominguez Channel levees
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue
Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF Version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Los Angeles County fault systems surrounding Carson is included in the following table.

Based on the earthquake shaking potential in the Los Angeles Basin, the proximity to the above listed fault systems, the probability of seismic ground shaking generating damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of the Dominguez Hills campus sits surrounded by areas composed of alluvial soils. In many cases, these sediment-based soils are loose and expose the potential for liquefaction. The

majority of the interior Los Angeles Basin has identified a moderate risk of liquefaction including neighborhoods on the north, south, and east of the campus.

The known fault systems generating the threat to Los Angeles County exist on all sides of the area including near the CSU Dominguez Hills campus. As such, the proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. Campus buildings and equipment will be exposed to significant damages resulting in reduction of services and capabilities of the campus to address post incident response and stabilization needs. The lack of earthquake insurance will cause extreme financial burdens on those affected.

Elements of the vulnerability to a major earthquake on the CSU Dominguez Hills campus will vary depending on when the earthquake were to strike. The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more earthquake resistant than older buildings as building codes and construction technology have improved. A locally centered earthquake, even from moderate events, would have the potential for more damaging results when associated with the moderate liquefaction zones of the area. This would particularly be seen with greater damages to unreinforced masonry buildings.

The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to
navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $142,163,477.

**Vulnerability Assessment Conclusions**

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the Los Angeles Basin and the CSU Dominguez Hills campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU Dominguez Hills campus and community.
In the event that a major earthquake was to strike along the fault systems surrounding Carson, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader Los Angeles Basin creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shock continue. These effects are magnified for populations having specific vulnerabilities or access limitations.

**Identified Data Limitations**

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Erosion**

**Description of the Hazard**

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.” Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

**Location of the Hazard**

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While

---

coastal erosion can happen in any storm, it is more likely during El Niño events, which occur every 5-7 years. As such, for the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across those areas of the CSU-Dominguez Hills campus with erosion-prone characteristics. While it is understood that such conditions exist generally, no specific locations under threat of erosion or erosion-in-process have been identified. Such an assessment may be conducted by campus leadership at some point in the future, given one previous occurrence which has been mitigated.

Other incidents of erosion, such as occurs around buildings, is relatively non-spatial and can occur in any locations with conducive soil structure and a source of movement, such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover.

Extent of the Hazard

Erosion is occurring on the Pacific coastline west of CSU Dominguez Hills. While there is no published scale of severity or extent for this geologic hazard on the CSU Dominguez Hills campus, erosion is likely to occur if conditions are favorable. However, given some historical occurrence of erosion on campus, the planning committee ranks the extent of this hazard as Moderate.

History of the Hazard

In 2014, an erosion problem on campus was causing silt to clog the draining pipes that transport water runoff from the health center. Grounds management crews improved water retention in the area by creating a miniature fairy garden.

Potential Impacts of the Hazard

Coastal erosion can result in severe impacts to infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

In agricultural areas, the erosion of soil degrades the quality of the soil, which can lead to reduced crop yields. At The Urban Farm, soil erosion can create significant concerns for agriculture and research. Eroded test plots can negatively impact experiments and tests, resulting in a loss of knowledge and data.

Probability of Future Occurrence of the Hazard

_____________________________

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion on campus, the probability of at least a limited degree of erosion taking place somewhere on campus in the future is High over the long term.

Vulnerability to the Hazard

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU Dominguez Hills infrastructure, buildings, and agriculture located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion. CSU leadership would consider performing an analysis on specific at-risk buildings, slopes and soil types in the future.

In the wider Carson community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality.

Estimate of Potential Losses

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks. Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

Vulnerability Assessment Conclusions

While the ability to predict future erosion on the CSU Dominguez Hills campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

Identified Data Limitations

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
**Extreme Temperatures (Includes Extreme Cold and Extreme Heat)**

**Heat**

**Description of the Hazard**

What is considered an excessively hot temperature varies according to the normal climate for that region. However, when temperatures are extremely high, people are at higher risk for heat-related illnesses, such as dehydration, heat exhaustion, heat stroke, and in severe cases, death.\(^{51}\)

Hazards from extreme heat are made worse when high temperatures are accompanied by high levels of humidity, which is defined as the amount of moisture in the air.\(^{52}\) As the temperature climbs, the air is able to hold more moisture. High humidity prevents the human body from cooling down naturally, which leads people to perceive that the temperatures “feels” hotter. The combination of temperature and humidity is known as the heat index.\(^{53}\)

Heat stroke, the most serious heat-related illness, occurs when the body is unable to control its temperature. Body temperature rises rapidly, the sweating mechanism fails, and the body cannot cool down.\(^{54}\) In extreme cases, heat stroke can cause confusion and unconsciousness, so the victim is unable to seek treatment without assistance.

There are several groups of people who are uniquely vulnerable to the effects of extreme heat, such as infants and children, older adults aged 65 and up, athletes and outdoor workers, low-income households, and individuals with certain chronic medical conditions.\(^{55}\)

**Location of the Hazard**

Extreme heat events are non-spatial hazards, and may occur anywhere at the CSU Dominguez Hills campus.

**Extent of the Hazard**

Extreme heat has a wide range of extent and severity markers and characteristics. Monthly average maximum temperatures in June through October range approximately from the mid-70s to upper-70s in Carson, California. Given no excessive heat events in the City of Carson since 1952, the planning committee ranks the extent of the hazard as **Low**.

\(^{53}\) Ibid.

The National Weather Service issues a Heat Advisory when the heat index value is expected to reach 100° – 104° F within the next 12 to 24 hours. Excessive Heat Warnings are issued when there is an anticipated heat index of 105° F or greater that will last for two (2) or more hours. Excessive Heat Warnings are issued by the county when any location in the county is expected to reach that criteria. In anticipation of an Excessive Heat Warning, an Excessive Heat Watch may be issued 1 to 2 days in advance, when the Heat Warning criteria is 50 – 79% likely to occur.

Figure 7-8 (following) depicts the National Weather Service’s methodology for determining the heat index, using the % humidity and the actual temperature.

Figure 7-9: Methodology for Determining Heat Index

As the heat index rises, so does the potential danger to people and animals. Table 7-24 (following) shows the health hazards associated with extreme heat.

Table 7-23: Health Risks Associated with Heat Index

<table>
<thead>

Sunstroke, heat cramps, and/or heat exhaustion is possible with prolonged exposure and/or physical activity.

Caution  
80° – 89° F  
Fatigue is possible with prolonged exposure and/or physical activity.

Based on no record of extreme heat events on campus, along with LA County’s established protocols of providing the public with advanced notice of heat events with directives for mitigating impacts, the planning committee ranks the extent of this hazard on campus as Low.

History of the Hazard

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, there have been no excessive heat events in the City of Carson since 1952. The larger Los Angeles County area has had five such events, all in 2007 and 2008.

Potential Impacts of the Hazard

Should an excessive heat event occur, CSU Dominguez Hills may experience impacts from extreme heat due to cancelled classes or postponed outdoor events in order to protect students, faculty, and staff from the weather.

In addition to the threat extreme heat poses to humans, high temperatures also pose a threat to utility production, which in turn threaten facilities and operations that rely on utilities. As temperatures rise, more people stay indoors, increasing the demand for air conditioning, fans, and other electronics. This puts a strain on the electrical grid, which can cause temporary outages. These outages can impact operations throughout campus, resulting in interruptions and delays in service. Outages may also negatively impact research efforts on campus, as the inability to maintain a steady, constant temperature may impact research specimens and experimental results.

Probability of Future Occurrence of the Hazard

There have been no extreme heat events in the City of Carson, California. Therefore, it is unlikely that the hazard will occur annually. Notably, the City of Carson does not include excessive heat events as a potential hazard in its local hazard mitigation plan. The County of Los Angeles considers extreme heat as a hazard, but only as one small part of a larger discussion regarding the effects of climate change.\textsuperscript{58} Based on these conditions, the planning committee ranks the probability of occurrence as \textbf{Low}.

Vulnerability to the Hazard

\textsuperscript{58} 2019 County of Los Angeles All-Hazards Mitigation Plan. \textit{4.1 Climate Change}. Print. Retrieved 01.27.21 from: https://lacounty.gov/emergency/county-of-los-angeles-all-hazards-mitigation-plan/
When dealing with an extreme heat event, the most common impacts are those generally felt by the people living in the targeted area. For people in particular, heat can kill when the body is pushed beyond its limits. Most heat disorders occur because the victim has been overexposed to heat. As discussed, the major human risks associated with extreme heat include dehydration, sunburn, fatigue, heat exhaustion, heat stroke, and in severe cases, death.

Some portions of the population are more at risk to the effects of extreme heat. The very young, the elderly, and certain groups with chronic medical conditions (such as asthma or other pulmonary illnesses, heart disease, poor blood circulation, neurological illnesses, and obesity) are generally more vulnerable to the effects of extreme heat, and are more likely to suffer illness or death as a result. 59 This is especially true if exposure is extended for a period of time and preventative measures are not taken immediately.

CSU Dominguez Hills is aware of the potential for extreme heat events as a campus located in the Southern area of the state, so while this is a hazard that the campus may experience, staff has enough familiarity with the hazard to handle the risks and vulnerabilities.

Estimate of Potential Losses

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

Vulnerability Assessment Conclusions

While the ability to predict future heat events at the CSU Dominguez Hills campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has warmed about three degrees on average over the last century, with less rainfall. This may lead to stronger heat events, drought, and an increased risk of wildfires. 60

Identified Data Limitations

Quantitative data on extreme heat impacts, such as public health impacts or impacts to campus power sources or air conditioning equipment is not available at this time.

Cold

Description of the Hazard

What is considered an excessively cold temperature varies according to the normal climate for that region. However, when temperatures are far below normal, with higher wind speeds, heat leaves the human body more rapidly, which increases the possibility of negative effects from these extreme temperatures.\textsuperscript{61}

The greatest danger from extreme cold is to people, as prolonged exposure can cause frostbite or hypothermia, and can become life threatening. When someone is suffering from hypothermia, body temperatures can become so low that they affect the brain, making it difficult for the victim to think clearly or move well. In the case of frostbite, the frozen tissue becomes numb and the victim may be unaware that anything is wrong until someone else notices.\textsuperscript{62} This makes hazards from extreme cold particularly dangerous, as people may not understand what is happening to them or what to do about it.

The primary hazards from extreme cold are frostbite and hypothermia. Frostbite is caused by freezing of the skin and underlying tissue. It causes a loss of feeling and color in the affected areas of the body, and most often affects the nose, chin, fingers, or toes.\textsuperscript{63} It can be permanently damaging if not treated promptly and can lead to infection, nerve damage, or amputation in severe cases.\textsuperscript{64} The risk of frostbite is increased in people with preexisting conditions, the elderly, people with reduced blood circulation, and people who are not dressed warmly enough for the conditions.

Hypothermia occurs when the body loses heat faster than it can produce heat, causing a dangerously low body temperature. A normal body temperature is around 98.6° F. Hypothermia occurs when your body temperature falls below 95° F.\textsuperscript{65} As this happens, the heart and other essential organs cannot work properly. If hypothermia is not treated, it can lead to heart failure, respiratory failure, and eventually to death.

Excessive or extreme cold can accompany severe winter weather, or it can occur without severe weather. For this reason, extreme cold is considered a separate hazard from severe winter storms.

Location of the Hazard

Extreme cold events are non-spatial hazards, and may occur throughout the CSU Dominguez Hills campus.

Extent of the Hazard

Extreme cold has a wide range of extent and severity markers and characteristics. Average nighttime winter temperatures in the City of Carson are typically

\textsuperscript{61} National Weather Service. \textit{Stay Safe in the Extreme Cold}. Retrieved 01.29.21 from: https://www.weather.gov/dlh/extremecold
\textsuperscript{63} Mayo Clinic. \textit{Frostbite: Overview}. Retrieved 01.29.21 from: https://www.mayoclinic.org/diseases-conditions/frostbite/symptoms-causes/syc-20372656
\textsuperscript{64} Ibid.
\textsuperscript{65} Mayo Clinic. \textit{Hypothermia: Overview}. Retrieved 01.29.21 from https://www.mayoclinic.org/diseases-conditions/hypothermia/symptoms-causes/syc-20352682

7-64
in the high 40s. Based on just 2 frost/freeze events in Los Angeles County since 1997, and no extreme cold events, the planning committee ranks the extent of this hazard as **Low**.

The National Weather Service issues Extreme Cold Warnings when the temperature feels like it is -30° F or colder across a wide area for a period of at least several hours. When possible, these advisories are issued a day or two in advance of the conditions.66

The most common extent/severity marker for extreme cold is the Wind Chill scale. Figure 7-9 (following) depicts the National Weather Service’s methodology for determining the wind chill, using wind speed and actual temperature. Although wind chill is not necessarily related to extreme cold as a single cause, the advisory system that the NWS currently uses relies on wind chill to relay warning and advisory information to the public. Extreme cold severity is a function of wind chill and other factors, such as precipitation amount (rain, sleet, ice, and/or snow).

Figure 7-10: Methodology for Determining Wind Chill

**History of the Hazard**

Based on data gathered from the National Centers for Environmental Information (NCEI) Storm Events Database, Los Angeles County has experienced two frost/freeze events, one

---

in December 1998 and one in January 2007, but no extreme cold hazards. *[Records for this hazard were first recorded in 1996]*.

**Potential Impacts of the Hazard**

Should an extreme cold event occur, CSU Dominguez Hills might experience impacts due to cancelled classes.

In addition to the threat posed to humans, extreme cold weather poses a significant threat to utility production, which in turn threatens facilities and operations that rely on utilities, specifically climate stabilization. As temperatures drop and stay low, increased demand for heating places a strain on the electrical grid, which can lead to temporary outages. These outages can impact operations throughout the campus, which can result in interruptions and delays in services. These outages may also negatively impact research efforts throughout the campus, as the inability to maintain a steady, constant temperature may result in unintended effects on research specimens.

**Probability of Future Occurrence of the Hazard**

The City of Carson has experienced freeze/frost events, but has never experienced an extreme cold event. Due to the City’s location and its fairly temperate climate, it is unlikely that this hazard will occur annually.

**Vulnerability to the Hazard**

When dealing with an extreme cold event, the most common impacts are those generally felt by the people living in the targeted area. As discussed, the major human risks associated with extreme cold include frostbite, hypothermia, and in severe cases, death. However, due to Carson’s moderate climate, the campus does not exhibit extreme cold vulnerabilities.

In summary, CSU Dominguez Hills is aware of the potential for extreme cold events, but due to its location, its climate is fairly moderate throughout the year and faces little risk of extreme cold events.

**Estimate of Potential Losses**

Based on the previous historical occurrences, annualized losses are considered to be negligible. In an extreme heat event, loss of human life or health impacts are a greater concern than is property damage.

**Vulnerability Assessment Conclusions**

While the ability to predict future extreme cold events at the CSU Dominguez Hills campus is limited, the effects of climate change may provide some information. According to the Environmental Protection Agency (EPA), Southern California has
warmed about three degrees on average over the last century, with less rainfall. This may lead to stronger heat events, drought, and an increased risk of wildfires.67

**Identified Data Limitations**

Numerous public and private actors conduct research, acquire data and disseminate meteorological information and forecasting to the general public, including the CSU university system. Currently, it is assumed that, apart from regular access to climate change models on changes to temperature extremes over time, the CSU community maintains sufficient access to the data needed to plan for, respond to, and mitigate the effects of extreme heat and cold.

---

Flood

Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Flooding represents one of the costliest and most frequent natural disasters that influence human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other features may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

- **Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.
Riverine Flooding – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the waterway exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

Localized Flooding – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

Infrastructure Failure – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

Coastal Flooding – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

Atmospheric River

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
The science behind atmospheric rivers

An atmospheric river (AR) is a flowing column of condensed water vapor in the atmosphere responsible for producing significant levels of rain and snow, especially in the Western United States. When ARs move inland and sweep over the mountains, the water vapor rises and cooks to create heavy precipitation. Though many ARs are weak systems that simply provide beneficial rain or snow, some of the larger, more powerful ARs can create extreme rainfall and floods capable of disrupting travel, inducing mudslides and causing catastrophic damage to life and property. Visit www.research.noaa.gov to learn more.

Location of the Hazard

CSU Dominguez Hills is found in the South Bay region in the City of Carson bordering the City of Long Beach. Carson is a community within the densely populated Los Angeles Basin. The entire CSU Dominguez Hills campus sits within a Special Flood Hazard Area (SFHA) Zone X: Area of Minimal Flood Risk designation on the Flood Insurance Rate Map. The neighborhoods south and east of the campus reside in a Zone X: Area with Reduced Flood Risk Due to Levee. See Figure 7-12 below. The access routes into and out of the campus servicing locations to the north and west are found in areas primarily designated as Zone X: Area of Minimal Flood Hazard, access routes to and from the south and east are primarily located in Zone X: Area with Reduced Flood Risk Due to Levee.

---

Figure 7-12: Special Flood Hazard Areas at CSU Dominguez Hills
Extent of the Hazard

The CSU Dominguez Hills campus resides in a minimally threatened flood zone. However, flood events are still possible and isolated heavy precipitation events can still pose flooding hazards. The CSU Dominguez Hills campus is located in general proximity to a number of flood control channels along the Los Angeles River and Rio Hondo systems. The Los Angeles River drains the San Gabriel Mountains and much of the Los Angeles Basin south towards Long Beach. A number of flood control systems feed into the Los Angeles River. The length of the Los Angeles River from downtown Los Angeles to the outlet into the ocean is a large concrete lined channel. The channel is located almost 3 miles east of the CSU Dominguez Hills campus, is separated from the campus by additional flood control channels and is lower in elevation than the campus.

The Dominguez Channel is a flood control and drainage channel ¾ mile southwest of the campus that drains much of the urban water collection of the South Bay communities. The CSU Dominguez Hills campus is situated slightly higher in elevation from the

---

69 FEMA Flood Map Service Center. Retrieved 05.05.2021 from: https://msc.fema.gov/portal/home
Dominguez Channel and is outside of the levee protected zone. In addition, the Compton Creek flood control channel is located approximately 2 miles east of the campus. The CSU Dominguez Hills campus is situated slightly higher in elevation from the Compton Creek and is outside of the levee protected zone. Based on the (above) factors, and no flood history on campus, the planning committee ranks the extent of the flood hazard on campus as **Low**.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

### Table 7-24: Flood Zone Designations and Descriptions

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no base flood elevations (BFEs) or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised maps in place of Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or BFEs are shown within these areas.</td>
</tr>
<tr>
<td>Zone AE</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. In most instances, BFEs derived from detailed analyses are shown at selected intervals within these zones.</td>
</tr>
</tbody>
</table>
Zone AH  
1%  
Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.

Zone AO  
1%  
Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.

Zone X (shaded)  
0.2%  
Represents areas between the limits of the 1% annual chance of flooding and 0.2% chance of flooding.

Zone X (unshaded)  
Undetermined  
Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain; areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot; areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFE or depths are shown within this zone.

History of the Hazard

Although flood events on campus have not been recorded, flooding in Carson and the broader Los Angeles County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and casualties. The following provides insight into information of past flooding events that are significant to the CSU Dominguez Hills campus.

### Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base

- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Inability for campus operations to resume
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

**Probability of Future Occurrence of the Hazard**

Flooding occurs on average every three years from heavy precipitation that could generate potential 50- or 100-year floods in the CSU Dominguez Hills area. That said, the location of the CSU Dominguez Hills campus residing within a Zone X (Area of Minimal Flood Hazard). As such, the planning committee rates the probability of future occurrence for flooding on campus as **Unlikely**.

**Vulnerability to the Hazard**

The CSU Dominguez Hills campus is subject to the effects of limited small-scale flooding or ponding resulting primarily from excessive precipitation and isolated strong storms. There is a more remote potential for flooding and damage on campus and surrounding residential and commercial areas of Carson due to overflow or damage to flood control systems. The flood control channels and drainage systems that surround the campus have limited storage or volume capacities.

Vulnerability to flooding on the CSU Dominguez Hills campus will vary depending on when the flood were to occur and the location of people and assets located within any low lying areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Members of the campus community may become trapped on campus depending on the level of flooding occurring on surface streets. However, in rare region-wide events this vulnerability may be extended to the homes and workplaces of members of the campus community and their families.

CSU Dominguez Hills is in proximity to a variety of industrial and petrol-chemical facilities. When these facilities are inundated with flood water, the potential for chemical release exists presenting possible exposures to individuals from the campus community.
These facilities additionally line many of the primary access routes in and out of the campus.

During low probability, severe flood events, some campus buildings and infrastructure in low lying areas might be vulnerable to large-scale flooding if it reaches the university. Campus utilities and communication capabilities could be impacted by flood waters rendering them disabled. A rare flood covering a large portion of the city might affect communication capabilities well beyond the boundaries of the campus. Remaining flood waters will leave behind molds and other health concerns in affected campus buildings and facilities likely requiring extensive restoration or demolishing. The residents of the on-campus residence halls, if located in low lying, flood prone areas, may have transportation limitations requiring evacuation and alternative housing procedures to be implemented if populated. In such areas, flood waters may result in damage to campus equipment, communication systems, protected documents, artwork, academic materials, computer systems, research, and other critical activities on lower levels of buildings.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $142,163,477. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over the campus and surrounding neighborhoods. The proximity to the Dominguez Channel, Compton Creek, and Los Angeles River presents additional flood risk factors for the campus.

As discussed above, those factors creating the potential for flooding in the Dominguez Hills area and on the campus generate the potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the campus community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water, while unlikely, has exponentially powerful impacts on particular segments of the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.
Hazardous Materials

Description of the Hazard

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

**Transportation Hazardous Materials Incident:** A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

**Pipeline Incident:** A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

- **Safety hazards** (fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)

---

73 California Department of Industrial Relations. *Worker Safety and Health During Fire Cleanup.* Retrieved 04.18.2021 from: [https://www.dir.ca.gov/dosh/wildfire/Worker-Health-and-Safety-During-Fire-Cleanup.html](https://www.dir.ca.gov/dosh/wildfire/Worker-Health-and-Safety-During-Fire-Cleanup.html)
• **Health hazards** (carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

**Natural-Technological Incidents (Natechs):** During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

**Location of the Hazard**

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system and/or within its surrounding communities. At larger scales (beyond the campus planning area) hazardous materials are located throughout the town of Carson, and the city and county of Los Angeles, and reflect different types, configurations and scales dispersed across these geographic areas.

**Extent of the Hazard**

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard. However, for the CSU – Dominguez Hills planning committee, although no hazmat events have taken place on campus, and hazardous materials are limited to chemicals in the science building, and fuel at the physical plant, based on the types and levels of hazardous materials in the larger community, it is prudent to rank the extent of the hazard for the CSU – Dominguez Hills campus as Moderate and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, 400 hazardous materials problems are tied to 32 past earthquakes, including more than 495 documented hazardous materials releases due to the Loma Prieta Earthquake alone (this number excludes innumerable leaks in Pacific Gas & Electric’s

---

natural gas distribution system).\textsuperscript{77} That said, it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 2021, a total of 2,096 spill events had occurred so far this year. Such events have occurred in all the cities and/or counties where CSU campuses are located.\textsuperscript{78}

No hazmat incidents have taken place on the CSU – Dominguez Hills campus.

Potential Impact of the Hazard

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – Dominguez Hills campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak\(^7\), which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health.\(^8\) Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with a science lab (including CSU – Dominguez Hills) is at risk of potential impact from a natural-technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials posing a threat to public and animal health, groundwater, and other parts of the environment. These hazardous materials may be released from damaged or flooded underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks, manure or human waste handling facilities, fertilizer and pesticide storage, agricultural sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed approximately 6,000 residences) entire neighborhoods can be burned to the ground. Hazardous material release creates public health concerns which can delay the initial steps of fire recovery, including reopening burned areas to residents and initiating debris removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with toxic substances due to the presence of synthetic and hazardous materials.

**Probability of Future Occurrence of the Hazard**

The probability of occurrence for a hazmat event on the CSU – Dominguez Hills campus can be viewed in two different ways: the history of occurrence serves as a sound predictor of future probability assuming current risk and vulnerability factors remain somewhat constant. For the purposes of the current estimate, no current data clearly indicates otherwise. As such, the probability of occurrence is Low because the CSU – Dominguez Hills campus has not experienced hazmat events. That said, hazmat occurrences are largely based on human error, and any changes in risk and vulnerability factors such as a decreased vigilance in materials oversight and handling practices or

changes in the amount of chemicals or exposure will likely increase the probability on campus.

**Vulnerability to the Hazard**

Hazardous materials pose a risk to the CSU – Dominguez Hills campus. As identified by the campus planning committee and on the hazmat map, the following vulnerabilities are present on campus: chemicals are present in the science lab and at the physical plant which, if spilled or released, could impact human health and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because (unlike natural hazards) the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control, given the complexity of how all natural and built environments and hazmat risks factors interrelate at the local or campus level, it is prudent to assume for planning purposes that the campus’ vulnerability is a sub-set of the larger community’s vulnerability. As such, the CSU – Dominguez Hills leadership maintains vigilance to mitigate the campus’ vulnerabilities identified above at a minimum.

**Estimate of Potential Losses**

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

**Vulnerability Assessment Conclusions**

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – Dominguez Hills) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Los Angeles County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – Dominguez Hills campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.
Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations

The CSU – Dominguez Hills planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
Landslide

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Niño storms or other high rainfall events may saturate soils and trigger slope failure.

Deep-Seated Landslides

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

Debris Flows Related to Shallow Landslides

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within the deposition zone and can result in downstream flooding. Post-fire debris flows often occur during the fall and winter following major summer fires.

Location of the Hazard

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high

---

earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 7-13. Based on Figure 7-13 (below), the east/southeast border of the CSU-Dominguez Hills campus is located adjacent to a class V landslide susceptibility area.

Figure 7-14: Deep-Seated Landslide Susceptibility Surrounding CSU-Dominguez Hills

Extent of the Hazard

In Los Angeles, landslides are more likely to occur in the steep slopes outside of Los Angeles and along the coastline. The San Gabriel mountains, both steep and erosive, contain steeply walled canyons above areas with high population density. When heavy rain occurs, there is significant potential for floods and landslides throughout the County, and the indirect impacts of landslides may cover a larger geographical extent. Given the campus’ location somewhat adjacent, but not connected to the moderate) landslide zone,

and no history of occurrence on or near the campus, the planning committee ranks the extent of the hazard as **Low**.

**History of the Hazard**

FEMA has declared thirteen major disasters involving landslides, mudslides, debris flows, or mud flows in Los Angeles County since 1978. NOAA has recorded five debris flow events in the County since 2004, most of which occurred in the areas directly surrounding metropolitan Los Angeles. The 2018 Southern California Mudflows damaged 40 to 45 homes in Sun Valley and caused a vehicle to strike a natural gas pipeline, which began to leak. No landslide events have occurred on the campus.

**Potential Impacts of the Hazard**

CSU Dominguez Hills may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly effect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

**Probability of Future Occurrence of the Hazard**

Slope failures are often triggered by other natural hazards such as heavy rainfall and earthquakes, so landslide frequency is somewhat related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in the San Gabriel Mountains and therefore are highly likely to occur in the future. Given the location of the campus adjacent but not connected to the landslide zone, and no occurrence of landslides on or near the campus, the planning committee ranks the annual probability of the landslide hazard for the campus as **Unlikely**.

**Vulnerability to the Hazard**

The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent.
and susceptibility to physical distress. Based on the mapping, the CSU-Dominguez Hills campus may exhibit building and/or infrastructure vulnerabilities to some degree at its east/southeast border. See the landslide location map in relation to the campus assets mapped adjacent to the identified landslide severity zones. Campus leadership may decide to more broadly assess asset vulnerability in the future.

Overall, any population proximal to a landslide when it occurs is vulnerable to its impacts.

**Estimate of Potential Losses**

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU Dominguez Hills.
Vulnerability Assessment Conclusions

Based on the campus’ proximity to a class V landslide zone, landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

Identified Data Limitations

The ability to predict future landslides at the CSU Dominguez Hills campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.
**Power Outage**

Description of the Hazard

Dominguez Hills is a large community in southern Los Angeles County that makes up the South Bay along with cities like, San Pedro, Redondo Beach, Carson, and others. The area is bounded by the Pacific Ocean on the south and west and generally by the City of Los Angeles on the north and east. The South Bay of Los Angeles is home to major refinery and industrial facilities, along with the peninsula where LA’s largest shipping yards lie, all of which rely on consistent electrical power.

Most aspects of modern life rely on the near continuous availability of utilities, such as electricity, water, and natural gas, and CSU Dominguez Hills is no exception as it is a highly populated community within one of the county’s most densely populated areas. An interruption in the supply or distribution of these services can leave highly populated areas, like Dominguez Hills, without electricity or sanitation. These interruptions can produce cascading effects from other hazards, such as major windstorms, leading to intentional disruptions of transmission lines due to safety concerns.

A power outage event can interrupt day-to-day operations of the campus, like in-person classes, impede, or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center and close restaurants around campus and outside the campus. Additionally, thousands of CSUDH student residents in on-campus housing would also be affected by a power outage on campus and in the surrounding area.

An electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of **intentional** disruptions:

- Planned: Some disruptions are intentional and can be scheduled based maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.
Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
- Tree contact other than from storms.
- Vandalism or intentional damage.
- Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
- Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

Extent of the Hazard

In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO) which is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities. CAISO is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are as follows:

- Stage 1 - reserve margin falls below 7 percent.
- Stage 2 - reserve margin falls below 5 percent.
- Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.
History of the Hazard

CSU Dominguez Hills has experienced power outages for various reasons. The university worked with the community’s local electric utility company to restore energy to the campus for its facilities, assets, resident halls, and classrooms. CSU Dominguez Hills has experienced power outages in the past and has experienced impacts because of the outages.

In 2015, a thirty-minute power outage affected the campus, which resulted in the majority of the campus losing power. The blackout was due to Southern California Edison repairing over-head wires located near the campus. The repair was due to a blown fuse that affected the campus. The majority of the campus reported losing power which affected lights, computers and Wi-Fi enabled devices. Classrooms were not evacuated as it was deemed safe for students, staff and faculty were deemed safe to remain in their classes and offices.

Potential Impacts of the Hazard

Instructors, campus residents, staff and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations. Electrical power is the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are
projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

**Probability of Future Occurrence of the Hazard**

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. Dominguez Hills, Carson and LA county experience such outages. As such, the probability ranking for the Carson area is Likely; although the campus may have recorded fewer events than the surrounding area, based on campus history of events, it is prudent to assign this same **Likely** ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

**Vulnerability to the Hazard**

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people, power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

**Estimate of Potential Losses**

The data provided by Cal State Dominguez Hills does not report any value for potential losses due to power outage.

**Vulnerability Assessment Conclusions**

The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Channel Islands. Safety and operations protocols center on the following “direct impact” set of concerns:

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and, to maintain a safe campus environment and visibility during nighttime hours. The vulnerable population (especially students with physical disabilities) may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors, and locks and lights may impede on a disabled student’s ability to travel and utilize the campus and its structures safely.
The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

**Identified Data Limitations**

Cal State Dominguez Hills did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
**Volcano (Associated Air Quality)**

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet.

The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU Dominguez Hills or Los Angeles County is located within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein two (2) inches or more of ashfall following an eruption is possible. While CSU Dominguez Hills does not fall within an estimated ashfall zone, lighter dustings of ash outside of those zones may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as **Low**.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic

---

eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU Dominguez Hills is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU Dominguez Hills.

The potential impacts of gases released during volcanic eruptions are as follows:

- Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.
- Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.
- Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.
- Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability of the Hazard

Populations living near volcanoes are the most vulnerable to eruptions and lava flows. However, volcanic ash can travel and affect populations miles away. The location and thickness of ash in any given area is a function of the severity of the eruption and wind speed and direction. For CSU Dominguez Hills, there is low vulnerability to the immediate impacts of volcanic eruptions due to the limited area affected and remote potential of an eruption. In the event of a widespread ashfall event, the elderly, infants, and populations with existing respiratory disease will be at higher risk.
Estimate of Potential Losses

Impacts to critical infrastructure, agriculture, and property from ashfall have the potential to cause widespread disruption, damage, and economic loss throughout the state. In the event of a widespread ashfall event, impacts will be immediate.

Current modeling is not precise enough to allow for an assessment of potential losses from ashfall to structures or infrastructure on or surrounding the campus.

Vulnerability Assessment Conclusions

CSU Dominguez Hills is unlikely to experience the direct impacts of a volcanic event. While the campus may be indirectly impacted by ashfall elsewhere in the state, direct ashfall impacts are generally unlikely but possible in a widespread event. However, the likelihood of any volcanic eruption in the state impacting the campus is very low.

Identified Data Limitations

Not all active volcanoes in California have been zoned for hazards by the US Geological Survey. This, together with the infrequent occurrence of volcanic explosions and number of factors determining type and extent of impacts, make the quantification of potential loss difficult.
Wildfire

Description of the Hazard

While wildfires are a natural part of California’s ecosystem, wildfires in California represent a hazard that presents one of the greatest probabilities of destruction along with a demonstrated history of catastrophic fire events in recent years. The destructive fire seasons of 2017 to 2020 illustrated the destructive forces fire presents to communities across the state. Wildfires may result in the structural loss, infrastructure loss, dangerous air quality, environmental damages, economic impacts, injuries, and loss of life. In many communities throughout California, wildfire presents greatest risk to human life and property.

Wildfires have been defined as any free burning vegetation fire that initiates from an unplanned ignition, whether natural or human caused demanding fire suppression actions to contain. These fires are prone to become uncontrolled, spreading through vegetative fuels rapidly exposing people and structures to harm. Wildfires present a significant risk to communities across the state, as evidenced by increasing trends of structural losses from wildland fires. This risk is elevated in areas where development and community growth has intersected, also known as the wildland-urban interface (WUI). In the interface setting, development itself can provide additional fuel for large fires. Recent fires have also demonstrated the ability of fire to consume populated areas in extreme conditions.

California’s Mediterranean climate in combination with its geography and vast population create a combination of factors that promotes an optimal environment for large fire growth and consequences. As there is great diversity of geographic characteristics across the state, the risks and potential consequences of wildfire must be assessed locally. The physical location, weather patterns, local fuel types and volume, extent of the WUI, topography, and additional factors will factor differently from part of the state to another.

The behavior of wildfires in California is significantly influenced by three distinct geographic factors. These factors will help shape the size, direction of spread, rate of combustion, fire intensity, and ability to pre-heat fuels. The physical factors contributing to wildfire behavior include:

- **Topography** – The rate in which wildfires spread increases with greater slopes in topography. The greater the slope will result in more pre-heating of fuel above the advancing fire. The direction that a slope faces will also influence fire behavior as south facing slopes receive greater solar radiation and thus drier vegetation that is more susceptible to combustion. Ridgetops often denote the end of fire spread as fire has greater difficulty spreading downhill.
- **Weather** – Weather factors substantially in influencing the behavior of wildfires. Wind, temperature, humidity, lightning, and lack of precipitation all contribute to a

---

fire’s ability or inability to spread and intensify. California routinely experiences conditions in which these factors are in alignment to contribute to extreme fire behavior during the summer and fall seasons. High winds, low humidity, and high temperatures provide an environment promoting extreme fire activity.

- **Fuels** – Certain types of vegetation are increasingly prone to igniting and promote more intense burning. Areas with greater “fuel loading” (amount of fuel present in terms of weight of fuel per unit of area) increases the amount of fuel to fuel a fire. Greater volumes of dead or dry vegetation compared to live plants is a critical factor. Vegetation during drought conditions will experience decrease in moisture content increasing the conditions for combustion. Fuels close proximity to one another allows for rapid spread through contact or radiant exposures.

A risk assessment for wildfires should be implemented within a geospatial context focusing on the specific location features and incorporates the three components of the wildfire risk triangle – likelihood, intensity, and susceptibility.

**Location of the Hazard**

Substantial portions of the State of California are exceptionally vulnerable to wildfire activity or reside in a wildland-urban interface (WUI) area due to the vast open spaces, rangelands, forests and other lands with high susceptibility to fire occurring throughout the state. CSU Dominguez Hills and the City of Carson are located in the southern end of the of the Los Angeles Basin. This region is dominated by urban and suburban communities with limited direct exposures to wildland fire. CSU Dominguez Hills has extensive residential neighborhoods to the north, south, and west of the campus. Large industrial land uses are located to the east of the campus and beyond the neighboring residential areas. The closest areas with a wildfire hazard is the Palos Verdes Hills 7 miles to the southwest. There are no open land uses that would provide an environment for large-scale wildfire development.

The CSU Dominguez Hills campus is located in the Los Angeles Basin surrounded by the Santa Monica, San Gabriel, San Bernardino, and Santa Ana Mountains. These mountain ranges host three national forests with extensive history of large fire development. The fires that burn in these areas have the potential to develop vast quantities of smoke that can fill the basin in the right wind conditions. The geography of the Los Angeles Basin and San Gabriel, San Fernando, and San Bernardino Valleys creates a topography that captures air pollutants including smoke with surrounding mountains and inversion layers. The CSU Dominguez Hills campus is located in a region in which wildfire smoke can saturate the air around the campus.
Extent of the Hazard

The area immediately surrounding the CSU Dominguez Hills campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones, and the campus does not have a history of wildfire activity occurring within proximity to the campus. Although the campus is not surrounded by High fire severity zones, given frequent events in the San Gabriel mountains surrounding the campus, and the extensive history of wildfire related smoke impacting the campus, the planning committee ranks the extent of the wildfire hazard for the campus as Moderate.

The National Fire Danger Rating System (NFDRS) is the current system in use for rating and classifying the potential danger of fire. The NFDRS tracks the effects of previous weather events on both dead and live fuel loads and adjusts accordingly based on future or predicted weather conditions. These complex relationships and equations are computed, and the outputs are expressed in terms that users can quickly and easily

understand. The current NFDRS is used by all federal and most state agencies to assess fire danger conditions.

The following table depicts the NFDRS, from the US Forest Service’s Wildland Fire Assessment System.

Table 7-27: National Fire Danger Rating System

<table>
<thead>
<tr>
<th>Rating</th>
<th>Basic Description</th>
<th>Detailed Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS 1: Low Danger (L)</td>
<td>Fires not easily started</td>
<td>Fuels do not ignite readily from small firebrands. Fires in open or cured grassland may burn freely a few hours after rain, but wood fires spread slowly by creeping or smoldering and burn in irregular fingers. There is little danger of spotting.</td>
</tr>
<tr>
<td>COLOR CODE: Green</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 2: Moderate Danger (M)</td>
<td>Fires start easily and spread at a moderate rate</td>
<td>Fires can start from most accidental causes. Fires in open cured grassland will burn briskly and spread rapidly on windy days. Woods fires spread slowly to moderately fast. The average fire is of moderate intensity, although heavy concentrations of fuel -- especially draped fuel -- may burn hot. Short-distance spotting may occur but is not persistent. Fires are not likely to become serious and control is relatively easy.</td>
</tr>
<tr>
<td>COLOR CODE: Blue</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 3: High Danger (H)</td>
<td>Fires start easily and spread at a rapid rate</td>
<td>All fine dead fuels ignite readily, and fires start easily from most causes. Unattended brush and campfires are likely to escape. Fires spread rapidly and short-distance spotting is common. High intensity burning may develop on slopes or in concentrations of fine fuel. Fires may become serious and their control difficult, unless they are hit hard and fast while small.</td>
</tr>
<tr>
<td>COLOR CODE: Yellow</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CLASS 4: Very High Danger (VH)</td>
<td>Fires start very easily and spread at a very fast rate</td>
<td>Fires start easily from all causes and immediately after ignition, spread rapidly and increase quickly in intensity. Spot fires are a constant danger. Fires burning in light fuels may quickly develop high-intensity characteristics - such as long-distance spotting - and fire whirlwinds when they burn into heavier fuels. Direct attack at the head of such fires is</td>
</tr>
<tr>
<td>COLOR CODE: Orange</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

rarely possible after they have been burning more than a few minutes.

Fires under extreme conditions start quickly, spread furiously, and burn intensely. All fires are potentially serious. Development into high intensity burning will usually be faster and occur from smaller fires than in the Very High Danger class (4). Direct attack is rarely possible and may be dangerous, except immediately after ignition. Fires that develop headway in heavy slash or in conifer stands may be unmanageable while the extreme burning condition lasts. Under these conditions, the only effective and safe control action is on the flanks, until the weather changes or the fuel supply lessens.

Due to the impacts of wildfires on public health, agencies across the nation have adopted the use of the Air Quality Index (AQI) to communicate and provide a consistent approach to air quality measurements and categorization. The AQI primarily focuses on the health effects caused by pollutants in the air such as smoke. The goal of the AQI is to provide advisories to assist the public in determining when to reduce exposures to inhalation of air pollution as pollution levels rise.

Table 7-28: Air Quality Index for Ozone and Particulate Pollution

</table>

### History of the Hazard

The State of California has a long history of chronic and destructive wildfires throughout the state. On average, 8,300 wildfires have caused burnt 928,245 acres across the state over the 20-year period between 2000 and 2020. Los Angeles County also has a long history of wildfire activity primarily in the foothills and mountains of the San Gabriel and Santa Monica Mountains. Wildfires occurring in Los Angeles County have resulted in hundreds of thousands of acres burned and hundreds of millions of dollars in damages.

The area immediately surrounding the CSU Dominguez Hills campus is not in proximity to fire hazard zones designated as a High Fire Hazard Severity Zones. The campus does not have a history of wildfire activity occurring within proximity to the campus. However, the County is surrounded by areas that are considered to be of high fire threat that would produce vast quantities of smoke and particulates into the air. The Dominguez Hills campus has experienced multiple days of poor air quality due to fires burning in Los Angeles, Orange, Riverside, and San Bernardino Counties. The 2017, 2018, and 2020 fire seasons in particular illustrated the increase in wildfire generated smoke saturating the air of communities throughout the state including Los Angeles County. CSU Dominguez Hills personnel reported the ongoing development of policies and procedures to address the response to poor air quality days.

### Potential Impacts of the Hazard

The location of the CSU Dominguez Hills campus surrounded by areas or urban development removed from areas with a fire hazard places a minimal direct threat from wildfire to the campus. The potential impacts to wildfire exist with members of the campus community who reside or work in these fire hazard zones.

Potential impacts to the campus community resulting from wildfires include:

---

90 California Department of Forestry and Fire Protection. *Stats and Events*. Retrieved 05.03.2021 from: [https://www.fire.ca.gov/stats-events/](https://www.fire.ca.gov/stats-events/)
• Injuries or loss of life
• Campus property destruction or damage
• Residential property destruction or damage
• Commercial property destruction or damage
• Loss of property contents
• Infrastructure damage
• Damaged or destroyed lifelines/supply routes
• Damaged or destroyed utilities
• Damaged or destroyed critical facilities supporting campus emergency support needs
• Loss of community economic base
• Employment losses
• Loss to ground supporting vegetation on hillsides resulting in erosion or landslides in future precipitation events
• Agricultural (crops and livestock) damages or destruction
• Environmental damage
• Societal and community impacts
• Damage to organizations and facilities providing support services to vulnerable populations
• Greater evacuation challenges for those most vulnerable
• Psychological impacts of impacted populations
• Disruptions to education delivery to community

Potential impacts resulting from wildfire generated smoke include:
• Dangerous levels of air pollution
• Human Health Effects
• Air conditioning systems overwhelmed
• Greater demands on air filtration systems
• Greater demands on healthcare systems
• Reduced outdoor work productivity
• Closures of academic sessions

Additionally, there remains a number of secondary impacts from wildfires that could affect the campus community. Utilities feeding areas of Los Angeles County including the campus may be damaged resulting in power outages. Fire related damage in the watersheds will likely cause future landslides, degradation to plants supporting hillsides, and impact the hydroelectric power capabilities. Fires may present threats to areas of recreation, scenic value, and wildlife that are a part of the culture of the campus community.

Probability of Future Occurrence of the Hazard

The CSU Dominguez Hills campus is located in an area not considered to have a high wildfire risk, as it is not in proximity to fire hazard zones designated as a High Fire Hazard
Severity Zones. Also, the campus does not have a history of wildfire activity occurring within proximity to the campus. Furthermore, the location of the CSU Dominguez Hills campus surrounded by densely developed residential, commercial, and industrial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities. Based on the wildfire threat potential in the area surrounding the CSU Dominguez Hills campus, including the distance to Fire Hazard Severity Zones and density of residential and commercial development, the probability of wildfire related damage is considered Unlikely.

Based on the wildfire threat potential in the area surrounding the Dominguez Hills campus, and the frequency of wildfire events in Southern California including the hills and mountains throughout Los Angeles County, the probability of wildfire smoke impacts is considered Likely.

Vulnerability to the Hazard

The CSU Dominguez Hills campus is not likely to be subject to direct impact from wildfire due to the campus location in an urban/suburban area of Carson. The vulnerabilities to the effects of wildfire would largely lie within the campus community who may reside or work in locations that are exposed to the Fire Hazard Severity Zones outside of Carson. Wildfires occurring in other areas of the region may result in the displacement of large numbers of people. These effects may spill onto the campus in the form of evacuees or facility support to emergency resources.

Fire directly threatening the campus would likely take the form of localized fires involving single structures or small areas. Smaller vegetation fires are possible surrounding the campus in the urban forest or fields surrounding the city. These incidents would likely have little impact to the campus.

The primary basis of vulnerability is based on the population affected and the built environment exposed. In general, newer construction will be more fire resistant than older buildings as building and fire codes and construction technology have improved. Density of buildings and proximity of fuels to buildings or equipment at risk of combustion would additionally influence the fire’s ability to spread to structures.

The greater concerns regarding vulnerabilities to wildfire on CSU Dominguez Hills are related to the smoke that fires in the area would produce. The recent summer seasons have clearly demonstrated the reality of large wildfires producing enough smoke to fill the Los Angeles Basin even from substantial distances away. These recent fires have displayed how the effects of this smoke impact the general population and especially vulnerable populations. CSU Dominguez Hills students, faculty, and staff both on campus and off campus face these same vulnerabilities related to smoke filled air.

Smoke generated from large wildfires pose a threat in terms of diminished air quality that would be exposed to the population within the area of smoke distribution. Individuals with existing health problems such as respiratory or cardiac illnesses are increasingly vulnerable to wildfire generated smoke. Staff who work in roles requiring outdoor activity will be increasingly exposed during days where the air quality index is considered
unhealthy or worse. Student athletes participating in outdoor sports and engaging in aerobic activities are increasingly vulnerable to the effects of wildfire.

The vulnerability to members of the campus community in which wildfire generated smoke on the CSU Dominguez Hills campus will vary depending on when the air quality was to reach unhealthy levels. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Vulnerable populations will likely face disproportionate health safety issues from smoke filled air, experience increased stresses, may require the need to remain away from the campus enclosed at home, and may find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. Costs would also be likely to include mitigation or repairs of HVAC systems, sealing of doors and windows, and other methods of keeping smoke from entering buildings. Secondary costs would include lost academic days during campus closures, lost staff on campus productivity, and health and medical interventions for affected members of the campus community.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to wildfire are $142,163,477. Due to the lack of a complete inventory of building and facility costs, the total replacement estimate is likely much higher. However, the location of the campus in an urban/suburban setting removed from hazard prone areas makes wildfire related damages unlikely.

Vulnerability Assessment Conclusions

The occurrence of wildfires has been a frequent event in Los Angeles County; however, wildfire incidents do not pose a direct risk to the CSU Dominguez Hills campus. The location of the CSU Dominguez Hills campus surrounded by densely developed residential, commercial, and industrial land uses mitigates any vulnerabilities of wildfire hazards to the campus community or facilities.

Communities located within or near the Wildland Urban Interface may be subject to damaging fires. These same communities may be home to members of the campus community. The students, faculty, and staff of CSU Dominguez Hills who live or work in these hazard areas may experience vulnerabilities to the direct exposure to wildfire not likely at the campus. These effects may create tremendous challenges that could impact their ability to maintain engagement with university academic or professional activities. The potential for large-scale wildfires in the region further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards.

Additionally, the topography of Southern California surrounded by mountains allows for smoke filled air to linger in the valleys of the Los Angeles Basin with the potential for unhealthy air quality depending on wind conditions. Fires in surrounding mountains generating tremendous quantities of smoke present tremendous health related vulnerabilities to members of the campus community. The campus community exposed to these unhealthy air conditions are vulnerable to a variety of potential health related effects.

Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

Severe Weather (Wind, Tornado, Hail, and Lightning)

Description of the Hazard

Severe weather can be described as a variety of weather or climate events that are beyond or near the ends of the range of observed weather patterns and behavior. These events can include high or extreme winds, storms, lightning, hail, tornadoes, heat waves,
unusually cold temperatures, extreme rainfall, and flooding. According to the Intergovernmental Panel on Climate Change (IPCC), to be classified as severe (or extreme), the occurrence of each value of a climate or weather variable (e.g., wind, hail, lightning, tornado, etc.) must be “above (or below) a threshold value near the upper (or lower) ends of the range of observed values of the variable.”

Severe weather in California can be generated by local, regional, and/or global weather and climate influences. From the individual thunderstorm to the Santa Ana wind event to the strong El Niño, damaging weather elements that are produced by and accompany severe weather and climate phenomena (e.g., damaging winds, hail, lightning, and tornadoes) occur throughout California and the California State University (CSU) system.

Global Scale Influences on Severe Weather in California: El Niño, La Niña, and ENSO

The El Niño-Southern Oscillation (ENSO) is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. On periods ranging from about three (3) to seven (7) years, the surface waters across a large swath of the tropical Pacific Ocean warm or cool by anywhere from 1°C to 3°C, compared to normal. This oscillating warming and cooling pattern, referred to as the ENSO cycle, directly affects rainfall distribution in the tropics and can have a strong influence on weather across the United States and other parts of the world.

El Niño and La Niña are extreme phases of the ENSO cycle, with a third phase occurring between them called the Neutral phase. The El Niño phase is characterized by unusually warm ocean temperatures and weaker-than-normal east winds in the Equatorial Pacific, while the La Niña phase is characterized by unusually cold ocean temperatures and stronger-than-normal east winds in the Equatorial Pacific. Both extreme ENSO phases lead to significant differences from the average ocean temperatures, winds, surface pressure, and rainfall across parts of the tropical Pacific. The Neutral phase indicates that conditions are near their long-term average.

---

93 Retrieved on 07.18.2021 from https://www.weather.gov/mhx/ensowhat
95 Retrieved on 07.17.2021 from https://www.climate.gov/news-features/understanding-climate/el-ni%C3%B1o-and-la-ni%C3%B1a-frequently-asked-questions
The extreme ENSO phases affect the frequency and intensity of weather events across the world, including in California. On average, areas across California experience exceptionally stormy winters with increased precipitation under El Niño conditions, but experience less stormy and drier winters under La Niña conditions. This variability in storminess and precipitation brought on by El Niño and La Niña events affects the both the frequency and intensity of severe weather conditions experienced by all CSU campuses, including CSU Dominguez Hills.

Regional Climate Influences on Severe Weather across California

Most of the weather in California is influenced by the wet-winter/ dry-summer Mediterranean climate pattern. In the summer months, Pacific storm tracks are deflected north due to the position of the Pacific High (i.e., a large-scale atmospheric circulation over the Northeast Pacific Ocean), preventing Pacific storms from reaching California. As a result, most summer storms are generated due to the incursion of moist air from the Gulf of Mexico or the Gulf of California, and occur as scattered, locally heavy showers in the desert and mountain regions of the state. In the winter months, the Pacific High decreases in intensity and moves south, permitting powerful Pacific storms to move into and across the state; these storms can produce extreme winds, heavy rains (including “atmospheric river” events), and widespread coastal and inland flooding. (Please see the Flood Hazard profile in this document for information on Floods.) As a result, storm events accompanied by precipitation in California are far more frequent in the winter months than they are in the summer months.

While the Mediterranean climate pattern influences the seasonal frequency, intensity, geographic spread, and type of some severe weather events CSU campuses experience (including CSU Dominguez Hills), other severe weather phenomena may occur in California at any time of the year. For example, near the coast and over the Central Valley, there appears to be no defined seasonality to thunderstorms, and these storms are usually light and infrequent. Thunderstorms are more intense and more frequent in the intermediate and higher elevations of the Sierra Nevada, and occur with greater frequency during the summer months.

Types of Storms in California

The 2018 California State Hazard Mitigation Plan (SHMP) defines a storm as a violent atmospheric disturbance occurring over land and/or water that is distinguished by its strength, characteristics, and the scale of the resulting damage. The SHMP also lists the
following types of storms that produce hazardous conditions and potential damage throughout the state of California.\textsuperscript{101} These storms affect (in varying degrees) all CSU campuses, including CSU Dominguez Hills.

- **Thunderstorm**: A rain-bearing cloud that also produces lightning. Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{102} Thunderstorms are caused by an atmospheric imbalance from warm unstable air rising rapidly into the atmosphere. Lightning, which occurs during all thunderstorms, can strike anywhere.\textsuperscript{103} Thunderstorms can produce some of nature’s most destructive and deadly weather including tornadoes, hail, strong winds, lightning and flooding.\textsuperscript{104} *Severe thunderstorms* are more intense, violent, and dangerous thunderstorms. The National Oceanic and Atmospheric Administration (NOAA) defines a severe thunderstorm as any storm that produces one or more of the following elements: Damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado.\textsuperscript{105, 106}

- **Hailstorm**: a type of storm that precipitates round chunks of ice. Hailstorms usually occur during regular thunderstorms.\textsuperscript{107}

- **Wind storm**: marked by high wind with little or no precipitation.\textsuperscript{108}

- **Winter storm**: A storm that can produce a combination of freezing rain, sleet, heavy snow, and/or strong winds.\textsuperscript{109}

- **Coastal storm**: large wind-driven waves and/or storm surge that strike the coastal zone.\textsuperscript{110}

- **Ice storm**: Ice storms are one of the most dangerous forms of winter storms. When surface temperatures are below freezing, but a thick layer of above-freezing air
remains aloft, rain can fall into the freezing layer and freeze upon impact into a glaze of ice. In general, 8 millimeters (0.31 inch) of accumulation is all that is required, especially in combination with breezy conditions, to start downing power lines as well as tree limbs. Ice storms also make unheated road surfaces too slick to drive on. Ice storms can vary in time range from hours to days and can cripple small towns and large urban centers alike.111

- **Snowstorm**: A heavy fall of snow accumulating at a rate of more than 5 centimeters (2 inches) per hour that lasts several hours. Snowstorms, especially ones with a high liquid equivalent and breezy conditions, can down tree limbs, cut off power, and paralyze travel over a large region.112

**Severe Weather Hazard Elements: Wind Hazards, Hail, and Lightning**

This hazard profile concentrates on the following types of severe weather hazards: **wind hazards (including tornadoes)**, **hail**, and **lightning**. These hazards are produced by a variety of weather phenomena, including thunderstorms, coastal storms, winter storms, and topographically-enhanced downslope winds. While storm and downslope wind hazards are responsible for severe weather events across the CSU system, only the wind, tornado, hail, and lightning elements generated by these hazards are covered in this profile. (Storm-related hazards such as flooding and extreme temperatures are covered in other sections of this document.)

**Wind Hazards**

**Wind** is the horizontal movement of air past any given point. Wind begins with differences in air pressures; pressure that is higher at one point than another sets up a force, pushing the high towards the low pressure.113 Wind gusts are defined as “rapid fluctuations in the wind speed with a variation of 10 knots or more between peaks and lulls.” 114

Wind hazards in California take several forms: High Wind, Strong Winds, Thunderstorm Winds, Mountain-Valley (Downslope) Winds, and Tornadoes. These hazards are encountered across California, and have the potential to cause harm to or loss of life and/or property throughout California and the CSU system (including CSU Dominguez Hills).

**High Winds, Strong Winds, and Thunderstorm Winds**

---

The National Weather Service reports three (3) types of wind events that occur areas over land: High Winds, Strong Winds, and Thunderstorm Winds. Collectively, these reports are used to determine the frequency with which wind hazard events have affected areas across the U.S., including California.

High Winds

High winds are defined as sustained non-convective winds of 35 knots (40 mph) or greater lasting for 1 hour or longer, or gusts of 50 knots (58 mph) or greater for any duration (or otherwise locally/regionally defined). In some mountainous areas, the above numerical values are 43 knots (50 mph) and 65 knots (75 mph), respectively.\textsuperscript{115}

Strong Winds

Strong winds are defined as non-convective winds gusting less than 50 knots (58 mph), or sustained winds less than 35 knots (40 mph), resulting in a fatality, injury, or damage.\textsuperscript{116}

Thunderstorm Winds

Thunderstorm winds are winds that arise from thunderstorm convection (occurring within 30 minutes of lightning being observed or detected), with speeds of at least 50 knots (58 mph). They can also be winds of any speed (non-severe thunderstorm winds below 50 knots (58 mph)) producing a fatality, injury, or damage.\textsuperscript{117}

Please note: \textbf{Straight-line wind} is a term used to define any thunderstorm wind that is not associated with rotation. It is used mainly to differentiate from the rotational winds found in tornado-producing storms.\textsuperscript{118} However, it is not a term used in the NCEI Storm Events Database, and therefore cannot be used to determine severe weather history of or potential impacts to CSU campuses.

Tornadoes

A tornado is an extreme severe weather wind hazard. A tornado is a rapidly rotating column of air extending from a thunderstorm to the surface of the Earth.\textsuperscript{119} This column extends between cloud and the Earth’s surface. The damage from tornadoes comes from the strong winds they contain and the flying debris they create. It is generally believed that rotational wind speeds can be as high as 300 mph in the most violent tornadoes.\textsuperscript{120} On a local scale, tornadoes are the most violent and most destructive of all atmospheric phenomena.\textsuperscript{121}

**Santa Ana Winds.** A type of wind hazard that is peculiar to Southern California is called a *Santa Ana Wind.* Santa Ana winds are strong, topographically-enhanced, extremely dry downslope winds that originate inland and affect coastal southern California and northern Baja California (Mexico). They occur when air from a region of high pressure over the dry, desert region of the southwestern U.S. flows westward towards low pressure located off the California coast. This creates dry winds that flow east to west through the mountain passages in Southern California. These winds have a strong seasonal component; they are most common during the cooler months of the year, occurring from September through May. Santa Ana winds typically feel warm (or even hot) because as the cool desert air moves down the side of the mountain, it is compressed, which causes the temperature of the air to rise. If strong enough, Santa Ana winds can cause major property damage, and may present difficulties for airborne and seagoing transportation. They also may increase wildfire risk because of the dryness of the winds and the speed at which they can spread a flame across the landscape. (Note: The Wildfire hazard is profiled elsewhere in this document.)

Figure below illustrates the mechanisms involved in the generation of Santa Ana winds across Southern California.

---

**Diablo Winds.** The Diablo wind is another type of topographically-enhanced downslope wind phenomenon that occurs in the North-Central areas of California. Diablo winds are offshore wind events that flow northeasterly over Northern California’s Coast Ranges, often creating high wind speeds downwind of major canyons and over ridges, and extreme fire danger for the San Francisco Bay Area. Diablo winds are driven by a surface pressure gradient that forms in response to an inverted pressure trough that develops over California.  

**Sundowner Winds.** Sundowner winds are significant and potentially damaging downslope wind and warming events that periodically occur along a short segment of the southern California coast in the vicinity of Santa Barbara, CA. The unique topography of this coastal region promotes the development of Sundowner wind events: over a length of about 100 km, the coastline is oriented approximately west–east, with the adjoining narrow coastal plain bounded by a steeply rising (to elevations greater than 1200 m) and
coast-parallel mountain range. Called Sundowner winds because they often begin in the late afternoon or early evening, their onset is typically associated with a rapid rise in temperature and decrease in relative humidity, and the winds tend to blow from the north from the Santa Ynez Mountains to the coast of Santa Barbara County, California. During the more intense Sundowner wind events, wind speeds can be of gale force 39-54 miles per hour) or higher, and can even reach hurricane force (≥ 74 miles per hour) in the most extreme cases. Temperatures over the coastal plain, and even at the coast itself, can rise significantly above 37.8°C (100°F). Seasonally, Sundowner winds peak in March, April, and May, with a minimum during summer and a secondary peak in winter that often corresponds with Santa Ana winds. In addition to causing a dramatic change from the more typical marine-influenced local weather conditions, Sundowner wind episodes have produced significant wind-related property and agricultural damage, as well as conditions of extreme fire danger.126 127 128

Hail

Hail is a form of precipitation consisting of solid ice that forms inside thunderstorm updrafts.129 It is roughly round in shape and at least 0.2’ in diameter. Hail develops in the upper atmosphere as ice crystals that are bounced about by high velocity updraft winds; the ice crystals accumulate frozen droplets and fall after developing enough weight. The size of hailstones varies and is a direct consequence of the severity and size of the storm that produces them – the higher the temperatures at the Earth’s surface, the greater the strength of the updrafts and the amount of time hailstones are suspended, and therefore the greater the size of the hailstone.130

Lightning

Lightning is an electrical discharge produced by a thunderstorm. Lightning rapidly heats the air in its immediate vicinity to about 50,000°F - about five times the temperature of the surface of the sun. This compresses the surrounding air and creates a supersonic shock wave, which decays to an acoustic wave that is heard as thunder.131

The discharge may occur within or between clouds, between the cloud and air, between a cloud and the ground, or between the ground and a cloud.\textsuperscript{132} Lightning that is produced from thunderstorms in which precipitation evaporates before reaching the ground is called “dry lightning.”

**Location of the Hazard**

Severe weather is a non-spatial hazard, and can occur anywhere in the CSU system, including on the CSU Dominguez Hills campus. No one area of the campus – or of the surrounding community – is subject to experiencing severe weather more than any other area.

There is geographic variability among the different types of mountain and valley wind events (as a sub-category of the severe weather hazard). Santa Ana winds occur in Southern California, Diablo winds occur in North-Central California, and Sundowner winds occur almost exclusively in Santa Barbara County, California.

**Extent of the Hazard**

Severe weather hazards are non-spatial hazards that potentially affect all CSU Dominguez Hills campus areas equally. However, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used do not exist at the campus level, it is assumed that the same (or similar) severe weather risks to CSU Dominguez Hills reflect those of the surrounding community and County. As a result, all assets and people at CSU Dominguez Hills are at risk from the effects of severe weather and can expect to experience at least some (or the complete range of) endemic severe weather hazards. In consideration of the campus’ design, layout, and operations, the severe weather history and degree of severity in the Carson area, and the history and degree of severity of each severe weather sub-type identified by the extent scales (below), the campus planning committee ranks the overall extent of the Severe Weather hazard as **MODERATE**. See each sub-hazard below for the planning committee’s sub-type extent ranking.

**Wind Hazard: Non-Rotational**

The Beaufort Scale below is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale.\textsuperscript{133} First developed in 1805, it is still used today to estimate wind strengths.\textsuperscript{134}

Based on those extent ranking factors identified (above), the planning committee ranks the extent of non-rotational wind hazards as **MODERATE**.
**Extent: Tornado**

Tornadoes have their own severity/extent scale. Until 2007, tornadoes were measured and described according to the Fujita Scale.\(^{136}\)

In February 2007, use of the Fujita Scale was discontinued. In its place, the Enhanced Fujita (EF) Scale is used. The Enhanced Fujita scale considers how most structures are designed and is thought to be a much more accurate representation of the surface wind speeds in the most violent tornadoes. Like the original Fujita scale, the Enhanced Fujita scale is a set of wind estimates (not measurements) based on damage.

It is important to note the date that a tornado occurred. Tornadoes that occurred prior to February, 2007 are classified using the original Fujita scale and will not be converted to the Enhanced Fujita Scale.

Table below illustrates the Fujita Scale in use prior to February 2007.

Table 7-31: Fujita Tornado Scale (Pre-February 2007) \(^{137}\)

<table>
<thead>

**F4 Devastating tornado**  
207-260 mph  
Well-constructed houses leveled; structures with weak foundations blown off some distance; cars thrown and large missiles generated.

**F5 Incredible tornado**  
261-318 mph  
Strong frame houses lifted off foundations and carried considerable distances to disintegrate; automobile sized missiles fly through the air in excess of 100 meters; trees debarked; steel reinforced concrete structures badly damaged.

**F6 Inconceivable tornado**  
319-379 mph  
These winds are very unlikely. The small area of damage they might produce would probably not be recognizable along with the mess produced by F4 and F5 wind that would surround the F6 winds. Missiles, such as cars and refrigerators would do serious secondary damage that could not be directly identified as F6 damage. If this level is ever achieved, evidence for it might only be found in some manner of ground swirl pattern, for it may never be identifiable through engineering studies.

Table below illustrates the Enhanced Fujita (EF) Scale, currently in use. Tornadoes that have occurred since February, 2007 are classified using the Enhanced Fujita Scale.

Based on those extent ranking factors identified (above), the planning committee ranks the extent of the lightning hazard as **LOW**.

**Extent: Thunderstorms that Generate Wind, Tornado, Hail, and Lightning Hazard Events**

Thunderstorms are not explicitly identified as a severe weather category for this hazard profile. However, they are responsible for most tornado, lightning, and hail hazard events – as well as a significant number of wind hazard events – across California and the CSU system. While individual thunderstorms affect relatively small areas, there are many instances in which thunderstorms can cluster together and/or travel in a line over long distances, producing significant damage over large geographic areas.

A thunderstorm is classified as “severe” when certain meteorological parameters within the thunderstorm are reached (i.e., damaging winds or speeds of 58 mph (50 knots) or greater, hail 1 inch in diameter or larger, and/or a tornado). However, there is currently no
established, objective severity scale for thunderstorms.\textsuperscript{141, 142} That said, according to the \textit{Glossary of Meteorology} published by the American Meteorological Society (AMS), a thunderstorm is reported as \textit{light}, \textit{medium}, or \textit{heavy} according to following five (5) characteristics:

- the nature of the lightning and thunder;
- the type and intensity of the precipitation, if any;
- the speed and gustiness of the wind;
- the appearance of the clouds; and
- the effect upon surface temperature.\textsuperscript{143}

A thunderstorm may also be classified by the nature of the overall weather situation in which the thunderstorm is produced, including:

- \textbf{Airmass Thunderstorm:} A thunderstorm produced by local convection within an unstable air mass;\textsuperscript{144}
- \textbf{Frontal Thunderstorm:} An individual thunderstorm the initiation of which results from rising motion associated with a front, or a thunderstorm within a convective system generated and organized by frontal rising motion;\textsuperscript{145} or
- \textbf{Squall-line Thunderstorm:} An individual thunderstorm included within a squall line (i.e., a continuous or broken line of active deep moist convection frequently associated with thunder).\textsuperscript{146, 147}

Based on the extent ranking factors identified (above) in relation to campus layout and operations, and past event low degree of severity, the planning committee ranks the extent of the thunderstorm hazard as \textbf{LOW}.

History of the Hazard

Severe weather hazards have been an annual occurrence in Los Angeles County and on the CSU Dominguez Hills campus. Historical data for these hazards are presented below.

Historical Storm Data Collection: NCEI Storm Events Database

Historical information regarding severe weather hazards can be found using The National Centers for Environmental Information (NCEI) Storm Events Database. The Storm Events Database contains searchable, archived National Weather Service (NWS) storm data from January 1950 to April 2021, as entered by NOAA’s National Weather Service (NWS). Due to changes in the data collection and processing procedures over time, there are unique periods of record available depending on the event type. For example, from 1950 through 1954, only tornado events were recorded; from 1955 through 1995, only tornado, thunderstorm wind, and hail events were introduced into the database; from 1996 to present, 45 additional event types are recorded, including high wind, strong wind, and lightning events. To obtain the most accurate portrayal of severe weather event frequency, searches of the Storm Events Database are conducted using data collected since 01/01/1996. As a reminder, all official severe weather event data is at the county level. Severe weather data do not exist at the campus level. That said, it may be the case that the campus to some degree experiences the severe weather events reported for the surrounding community and County.

Wind Hazards (excluding Tornadoes)

Information obtained from the NCEI Storm Event Database website shows the number of events (or occurrences) of wind hazard events in Los Angeles County since 1996. Here, wind hazard events include all “High Wind,” “Strong Wind,” and “Thunderstorm Wind” storm reports.

- High Wind: at least 387 events, or approximately 15.28 events per year
- **Strong Wind**: at least 3 events, or 0.12 events per year

- **Thunderstorm Wind**: at least 43 events, or approximately 1.70 events per year

- **All Wind Hazard events** (excluding Tornadoes): at least 427 events, or approximately 16.86 events per year. (Note: This was determined by conducting a simultaneous search of the component wind hazards of high wind, strong wind and thunderstorm wind.)

Overall, in Los Angeles County, there have been at least 427 wind hazard events since 1996, excluding tornadoes. That translates to an approximate average historical frequency of occurrence of 16.86 wind hazard events per year.

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 433 events) and simultaneous Database searches of all severe weather hazard events (i.e., 427 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Los Angeles County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County. When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 427 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical Wind Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the wind hazard events that Los Angeles County has experienced since 1996 have been costly. There have been 2 deaths and 4 injuries reported from wind hazard events (excluding tornadoes) in Los Angeles County; no property or crop damage has been reported.158

**Tornado Wind Hazards**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 12 reported events of tornadoes in Los Angeles County, which translates to approximately 0.47 tornado events per year.159

The vast majority of tornado reports in Los Angeles County since 1996 have been of tornadoes with a severity rating of F0/EF0. Only one (1) or 12 of the tornadoes reported in has been rated F1/EF1 or higher (it was an F1 tornado that occurred in 1998); that translates to approximately 0.04 events of F1/EF1 tornadoes have occurred per year in Los Angeles County.160

**Historical Tornado Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the tornado hazard events that Los Angeles County has experienced since 1996 have been minimal. There have been no deaths, or property or crop damage reported; however, 1 injury has been reported.161 (Note: The F1/EF1 tornado that occurred in Los Angeles County in 1998 caused the one (1) reported injury.)

**Hail**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 18 reported events of hail in Los Angeles County, which translates to approximately 0.71 hail events per year.162 (Note: The NCEI Storm Event Database search results for hail

162 National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from
indicate that there has been a total of 19 reports of hail since 1996. However, one (1) entry is for a hail event in San Diego County, over 100 miles away from Los Angeles County. The origin of this discrepancy is unknown at this time.

**Historical Hail Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the hail hazard events that Los Angeles County has experienced since 1996 have been costly. While there have been no deaths, injuries, or crop damages reported, property damage estimates have totaled approximately $3,500,000; the property damage estimate is from one (1) hail hazard event that occurred in 2003.¹⁶³ (Note: The San Diego County hail event that was included erroneously in the search results for hail events in Los Angeles County accounted for all reported injuries (i.e., 5) and crop damage estimates (i.e., $300,000) presented in the search results.)

**Lightning**

Information from the NCEI Storm Events Database indicates that since 1996, there have been 9 reported events of lightning in Los Angeles County, which translates to approximately **0.36** lightning events per year.¹⁶⁴

**Historical Lightning Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the lightning hazard events that Los Angeles County has experienced since 1996 have been costly. While no property or crop damages have been reported, there have been 2 deaths and 13 injuries attributed to lightning hazard events.¹⁶⁵

**All Severe Weather Hazard Events Recorded by the NCEI Storm Events Database**

Information obtained from the NCEI Storm Events Database indicates that there have been 466 occurrences of the severe weather hazard in Los Angeles County. This translates to 18.39 severe weather hazard occurrences per year.¹⁶⁶

Please note: Differences between the sums of individual component severe weather hazard event Database searches (i.e., 472 events) and simultaneous Database searches of all severe weather hazard events (i.e., 466 events) may be due to the following factors: (1) multiple event types are in the same record (e.g., "Thunderstorm Wind/Hail" or "Hail/Tornado;" and/or (2) severe weather hazard events such as “Thunderstorm Wind” or “Hail” that are reported for Los Angeles County have actually taken place hundreds of miles away, but are erroneously recorded as events that have occurred in the County.¹⁶⁷ When such a discrepancy arises, the more conservative aggregate hazard wind event value (i.e., 466 events) is used to determine the historical frequency of occurrence for the severe weather hazard. The origin of this discrepancy is unknown at this time.

**Historical, Aggregated Severe Hazard Losses for Los Angeles County since 1996**

According to the NCEI Storm Events Database, the severe weather events that Los Angeles County has experienced since 1996 have been costly. There have been 4 deaths and 18 injuries, and property damage estimates have totaled approximately $3,500,000; no crop damage has been reported. *It is important to note that for all Los Angeles County severe weather hazard events recorded on the Storm Events Database, lightning has accounted for half of the deaths, and 13 out of 14 (92.9%) injuries reported. However, hail has accounted for all reported estimates of property damage.*

**Wind Hazards Not Included in the NCEI Storm Events Database**

*Santa Ana Winds*

Santa Ana wind events occur at least twice per month from October through April.¹⁶⁸ From 1948 to 2012, total of 2056 events on the 65-year record were recorded in the Southern California region, yielding an average of 32 occurrences per year. Typical Santa Ana wind events last 1–2 days and represent 27% of the occurrences, with events lasting

---

¹⁶⁶ National Climatic Data Center. Storm Events Database. Retrieved 07.29.2021 from https://www.ncdc.noaa.gov/stormevents/listevents.jsp?eventType=%28C%29+Hail&eventType=%28Z%29+High+Wind&eventType=%28C%29+Lightning&eventType=%28Z%29+Strong+Wind&eventType=%28C%29+Thunderstorm+Wind&eventType=%28C%29+Tornado&beginDate_mm=01&beginDate_dd=01&beginDate_yyyy=1996&endDate_mm=04&endDate_dd=30&endDate_yyyy=2021&county=LOS%2BANGELES%3A37&hailfilter=0.0&tornfilter=0&windfilter=000&sort=DT&submitbutton=Search&statefips=6%2CCALIFORNIA

up to 6 days accounting for 90% of all occurrences. The remaining 10% are made up almost entirely of events lasting between 7 and 12 days.169 170

Figure below shows the mean monthly frequency per season of Santa Ana Wind events detected from 1948 to 2012. Extreme Santa Ana wind events are shown in dark red, and are defined as those events that are above the 90th percentile of all events on record.

Figure 7-17: Mean Annual Frequency of Santa Ana Wind events (1948-2012)171 172

**Diablo Winds**

Diablo wind events occur approximately **2.5 events per year**. These events are most frequent during the fall and early winter seasons, with the highest frequency of events occurring in October. As a result, the highest risk of Diablo-wind-related damage is in the fall and early winter.\(^{173}\)

Figure below shows the monthly frequency of Diablo winds (along with average live fuel moisture content). The Diablo Wind data are derived from a 17-year climatology of San Francisco Bay Area regional surface weather stations.\(^{174}\)

Figure 7-18: Monthly Frequency of Diablo Winds and Average Live Fuel Moisture Content (Dashed Line)\(^{175}\)

**Sundowner Winds**

Strong sundowner wind events occur approximately **2-3 times per year**. These events can create sharp temperature rises, local gale force winds, and significant weather-related problems. Rare, “explosive” types of sundowner wind events occur about 6 times per century that present dangerous weather situations, generating extremely strong and hot winds that can reach gale force or higher speeds.\(^{176}\)

* Note: The Diablo and Sundowner wind hazards are not present in Los Angeles County. They are included here for information purposes only.

Potential Impacts of the Hazard

The significance (or priority) of a hazard’s potential impacts is based primarily on the frequency and resulting damage caused by the hazard, including deaths/injuries and property, crop, and economic damage. All assets and people within CSU Dominguez Hills campus areas are at risk from the effects of severe weather.

Wind Hazards (Including Tornadoes)

Wind hazard events have the potential to impact people, property, and operations on campuses across the CSU system. People caught in the open during an extreme wind event are exposed to high winds and debris, and could be injured or killed.

The habitability of buildings can be compromised (by damaging roofs, windows, or other weak points in the building envelope), leading to long-term operational issues for the campus. As with most university campuses, space is always at a premium at the CSU
Dominguez Hills campus, and the loss of any currently utilized space due to building or structural damage would likely disrupt operations and the University’s mission.

Extreme wind events can result in power failure, which would impact the operation of the campus. Fallen tree limbs and other potential transportation hazards may also cause disruption to the surrounding community and limit ingress/egress to the campus.

According to the 2013 City of Carson Natural Hazards Mitigation Plan (NHMP), wind storms (including wind hazards and tornadoes) are considered to be significant, and therefore to have a significant potential impact on both the City of Carson and (by extension) the CSU Dominguez Hills campus.177 However, the 2019 County of Los Angeles All-Hazards Mitigation Plan is climate-change-focused, and does not include explicitly any severe weather hazards in its hazard identification profiles and risk assessments.178 To accommodate both hazard mitigation plans’ wind hazard assessments, as well as NCEI Storm Events Database historical frequencies, wind hazards (excluding tornadoes) are identified here as having medium significance for and moderate impact on both the City of Carson and (by extension) the CSU Dominguez Hills campus. However, tornado hazards are considered to have low significance for and minimal potential impact on the city and on the campus area.

**Hail**

Hail typically impacts property by damaging structures, cars, and utilities as it falls. Dents in cars, broken glass, and holes in roofs are common impacts of hail. Injuries to people from hail are less common, though they can happen, as hail is a hard object falling in an unpredictable manner at a fairly high rate of speed.

According to both the 2013 City of Carson Natural Hazards Mitigation Plan (NHMP) and the 2019 County of Los Angeles All-Hazards Mitigation Plan, hail hazards are not explicitly identified to be significant hazards. Therefore, the hail hazard is considered to be of low significance and therefore to have minimal potential impact on the City of Carson and (by extension) the CSU Dominguez Hills campus.179 180

**Lightning**

---

Lightning strikes the United States about 20-25 million times a year.\textsuperscript{181} Although most lightning occurs in the summer months, people can be struck at any time of year. Since 1990, lightning has killed an average of 39 people each year in the United States, and hundreds more have been injured.\textsuperscript{182} Property losses due to lightning have been very costly across the U.S. For example, from 2005 through 2020, U.S. homeowner’s insurance claim payouts for lightning losses totaled approximately $15,334,600,000, or $958,412,500 worth of payouts per year.\textsuperscript{183} (Commercial claim payouts for lightning losses for the U.S. were not available.)

According to both the 2013 City of Carson Natural Hazards Mitigation Plan (NHMP) and the 2019 County of Los Angeles All-Hazards Mitigation Plan, lightning hazards are not considered to be significant enough to include as a profiled hazard. Therefore, the hail hazard is considered to be of low significance and therefore to have minimal potential impact on the City of Carson and (by extension) the CSU Dominguez Hills campus.\textsuperscript{184} 185

**Probability of Future Occurrence of the Hazard**

Areas throughout California, including all California State University (CSU) campuses, experience severe weather events every year, and future occurrences of such events are projected to increase in both their frequency and intensity. Unfortunately, neither the 2013 City of Carson Natural Hazards Mitigation Plan (NHMP) nor the 2019 County of Los Angeles All-Hazards Mitigation Plan has much (if any) explicit quantitative assessment on probability of future occurrence of severe weather hazards.\textsuperscript{186} 187 However, according to the NCEI Storm Events Database, some of the severe weather hazards have occurred in Los Angeles County at least once per year. Furthermore, while the severe weather hazard is a non-spatial hazard that affects all areas of the CSU Dominguez Hills campus equally, the smallest geographic unit of measurement for almost all official severe weather event data is at the county level. Because the severe weather data used in this assessment do not exist at the campus level, it is assumed that the severe weather probabilities for the

\textsuperscript{183} Retrieved on 07.21.2021 from https://www.iii.org/table-archive/20504
CSU Dominguez Hills campus reflect those of the surrounding community and County identified in the Table below.

Based on the data available the NCEI Storm Events Database, the severe weather hazard is expected to occur on (or otherwise impact) the CSU Dominguez Hills campus at least once on an annual basis. Therefore, the probability of future occurrence of the severe weather hazard for CSU Dominguez Hills is HIGHLY LIKELY. See Table below for probabilities of future occurrence for component severe weather hazards for the City/County and the campus.

Table 7-36: Severe Weather Hazard Probabilities of Future Occurrence for Los Angeles County and CSU Dominguez Hills

** Note: The Diablo and Sundowner wind hazards are not present in Los Angeles County, and therefore are not rated for probability of future occurrence. They are included here for information purposes only.

Vulnerability to the Hazard

People, structures, and assets on the CSU Dominguez Hills campus are all vulnerable to the impacts associated with severe weather. Infrastructure can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning, which can result in service interruptions and outages. Structures can be damaged or destroyed by hail, wind, tornadoes, thunderstorms, and lightning. People can be injured or killed by lightning, flying debris, hail, or extreme wind events. The CSU Dominguez Hills campus also has vehicles, as well as off-campus conference and recreational facilities, that are all vulnerable to a severe weather event.
Estimate of Potential Losses

Severe weather is a non-spatial hazard that affects the entire CSU Dominguez Hills campus. Each of the hazards associated with severe weather can result in losses throughout the planning area.

All structures within the CSU Dominguez Hills campus are at risk from severe weather. There are approximately 54 buildings on the main campus that could be damaged by wind, hail, and/or lightning. If even a fraction of these assets were to be damaged, the resulting estimated losses would still be in the millions of dollars. The total replacement costs due to severe weather hazard are $142,163,477 for 37 buildings, and are unknown for the remaining 17 buildings. An analysis of projected dollar losses to campus buildings from severe weather as a percentage of building replacement costs is not currently available, though CSU leadership may pursue such data in the future.

The population at the CSU Dominguez Hills campus varies throughout the day. As of Fall, 2019, CSU Dominguez Hills had 17,027 students and 1,761 faculty and staff; all are at risk from severe weather events, with 18,788 being directly vulnerable in this scenario.188 189

Vulnerability Assessment Conclusions

Severe weather presents a variety of hazards to the CSU Dominguez Hills campus. People, assets, infrastructure, and vehicles can all be damaged by this hazard, and losses can quickly begin to rise. In the aggregate, severe weather is a frequently occurring hazard (mostly in the form of wind hazard events) that presents a variety of risks to CSU Dominguez Hills.

It is evident that the CSU Dominguez Hills campus has vulnerabilities to and risks from severe weather hazard incidents, and that pre-event planning, communication, and mitigation efforts should be implemented. Public education and outreach regarding areas of shelter that could be used by campus populations during severe weather events is considered by campus leadership to be one viable mitigation option. The campus planning committee will continue to look for feasible and cost-effective options for the mitigation of severe weather risks going forward.

Identified Data Limitations

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies.

188 Retrieved on 07.19.2021 from https://www2.calstate.edu/csusystem/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx
Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) collects and maintains data about natural hazards in summary format, as well as occurrences, dates, injuries, deaths, and estimated costs for individual storm events. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a scale as small as a single campus.

The best available data and records have been used throughout this section. Where no data or records exist or could be located, that deficiency is noted.
7.4 Social Resilience Assessment

Overview

While every person is vulnerable to risk, individuals from diverse populations such as those with access and functional needs are disproportionately more vulnerable and may be at a higher risk to harm in a disaster event. In addition to physical vulnerabilities, the intersectionality between physical hazard risks and population social vulnerabilities must be considered to holistically address overall campus risk.

As inclusivity is a high priority for CSU, addressing campus risk and resilience must be done through the lens of inclusion and equity. Addressing social vulnerability is an increasingly critical requirement of state and national doctrines and described in Section 4.4 of the HVRA Base Plan. Every individual of the campus’s richly diverse population group needs to have the capacity, skills, and knowledge in order to understand, access, and participate in risk reduction and disaster response in ways that are meaningful to their own unique situation. In a campus community, having strong social support networks and active involvement in community disaster responses may negatively or positively impact these opportunities and reduce the resilience-building process. This section offers a glimpse into the CSU Dominguez Hills campus’s unique social construct, population demographics, strengths and concerns and presents a high-level assessment of the resilience, coping capacities and potential social vulnerabilities of students, staff and faculty. The research variables that were asked are often considered sensitive subjects, and few are traditionally included in emergency management/hazard mitigation planning.

This social resilience assessment of college campuses is the first of its kind in the nation. The research methodology unfolded as the interviews with campuses progressed. The assessment data presented are not definitive or authoritative. The answers, analysis, and suggested trends are strictly indicators for potential social risk. They do not represent an accurate data capture as limitations on the data gathering process influenced an ability to provide accuracy. This assessment provides indications of increased risk, not accuracy of response or a true reflection of the situation of the campus. The information presented is to be considered in the context of the more detailed system-wide CSU social vulnerability assessment that is included in the baseline HVRA.

Campus-Identified Populations of Concern

During the campus interview, the following responses were provided when asked, “In considering the diverse population group(s) amongst student body, faculty and staff, which are of the most concern in your emergency management planning?”
Table 7-37: High level summary of campus populations of concern.

<table>
<thead>
<tr>
<th>Question</th>
<th>Campus Response</th>
</tr>
</thead>
</table>
| Which population groups amongst the student body, faculty, and staff, are of the most concern for physical and social vulnerabilities in emergency management planning? | • First generation students  
• Populations with disabilities                                    |
| Which population groups are most difficult to reach in an event?        | Non-English-speaking students and employees           |
| Which population groups have little/limited support networks if impacted by an event? | Students who rely on university housing               |

Resilience Variables Related to Campus Emergency Management

The interviewees were asked to reflect on a set of 12 variables for the campus populations of student, faculty and staff: homelessness (*housing insecurity*), food security, health and wellness, disability/access and functional needs (*AFN*), racial equity, digital equity, communications, international students, immigrants/immigration status issues (*undocumented, DACA, etc.*), LGBTQI (Lesbian Gay Bisexual Transgender Questioning (or queer) Intersex), and transportation dependency. They were also offered an opportunity to add any other factor they wanted to include. The following two questions were asked:

- Is this factor a particular issue of concern for emergency management on your campus? Responses were summarized as **Very High, High, Medium, Low**
- Is this factor reflected in the emergency plans and processes for your campus? Responses were summarized as **Yes, No, In Progress, NA**

In order to provide a high-level qualitative response for the answers, the approach of averaging response was taken. If conflicting answers were expressed by the interviewees,
the answer (code) was averaged out. A detailed explanation of the response averaging approach is included in the base HVRA.

Qualitative Narrative: Campus Overview of Potential Resilience Vulnerabilities

The following are interview notes of interest:

- Nora Garcia is an experienced emergency management lead and understands the issues related to social vulnerability.
- Community approach and inclusion in the emergency management planning process and review has not happened there for the campus plans. Now working with the unions because they represent the areas of individuals in the front end. The whole community approach is biggest – with a newsletter tailored to specific groups.
- May need to start looking for translation services for emergency notification for the non-English speaking populations because have such a diverse pop with students and staff—it is a currently disconnect.
The housed population have basic needs folks who don’t have access to nutrition or technology, and nowhere else to go. Need a Plan B for housing. Many students are facing some type of homelessness.

Campus is located in a poor neighborhood, many low income; many African American and Hispanic make up the student base. Hispanics are number one student population and black is second.

Very high concerns regarding food security. Student affairs has a food drive; used to have a food pantry.

Health and wellness are definitely issues of concern. Developed six “Toro team” for employee success and wellness; has a chair to set up online platforms and opened up to expand to students; never been done (unclear meaning). Operates like a branch. Have “Nora’s Plan” – this sits in the campus COVID safety and response plan, and at some point, the plan will need to transition to the EOP. The group reports up to the EOC.

“EOC structure has been a lifesaver.”

Not sure they are doing enough for AFN.

Not sure if “they” are resourced enough, as the emergency manager is concerned.

Communications in COVID is only in English. Very concerned they are not doing enough to address non-English speaking populations. While not in the current plans, she has plans, including a marketing campaign.

The international students are aware of emergency management practices and resources.

Very concerned about immigrants/immigration status issues, different expectations, how a potential civil unrest related to the President’s order before revoked would have impacted the emergency management program. Concerned about fallout from issues related to the police chief sending messages to the community about ICE. Need to look at the fallout of the problems.

Campus High Hazards and Potentially Vulnerable Populations

This section provides a brief introduction to the link between socially vulnerable populations and a particular hazard type. While extensive research has been conducted on the impacts of hazards, not all linkages have been documented or published, and detail for finding them are beyond the scope of this assessment. It’s important to note, the intersectional nature of what makes an individual’s personal experience and resilience to an event is played out by unique factors for that individual or population. The nuanced social vulnerabilities often come from the social and physical environment in which a person is embedded.

In order to aid in further assessing campus resilience, below is a general description of the known impacts. From some hazards, the descriptions are robust, while others are only brief introductions.
Table 7-39: CSU Channel Islands *Highly Likely, Likely and Possible* Hazards

</tr>
</tbody>
</table>

**Communicable Diseases**

*TBD*

**Drought**

The 2012-2016 drought had severe effects on two vulnerable sectors of our population: those in low-income brackets, and those, especially Native Americans, who rely on subsistence fishing for their livelihoods. Water bills increased throughout the state. Due to rising water prices, for the working poor, many have paid four to five percent of their income for water. Since many CSU students are commuters, and many living with families, future drought impacts may potentially affect a percentage of non-resident students. NASA’s modeling shows that future droughts are likely to last longer and be more intense, even leading to “megadroughts” in the western states. Fresh water supplies are predicted to be full of extremes, with both droughts and extreme precipitation events being more severe. The interrelationship between drought and other hazard conditions may lead to a set of secondary impacts. Drought conditions lead to water quality issues due to loss of drinking water, increased fire danger that leads to drought-induced fires and elevated AQI levels, as well as extreme heat or prolonged heat events.

---

**Earthquake**

Impacts on populations from earthquakes are complex, with long-term implications on social stability for all populations. In addition to the physical impact exposure during a no-notice earthquake event and the social and logistical challenges of a recovering community, an earthquake can have lasting impacts long afterwards due to post traumatic stress disorder (PTSD).

Socioeconomic vulnerabilities of populations at risk were analyzed in the hypothetical yet scientifically realistic earthquake sequence that is being used to better understand hazards for the San Francisco Bay region during and after a magnitude-7 earthquake (mainshock) on the Hayward Fault and its aftershocks. In this study, the at-risk populations located in areas of concentrated damage are anticipated to experience longer recovery trajectories, increased long term housing displacement, and transportation impacts due to dependencies on transit dependencies. When neighborhood schools close, families with school age children may move to other areas to keep their children in schools. Persons with access and functions needs are likely to be more dependent on access to functioning medical, social and personal health care services that would be overwhelmed by the event and therefore increasing their vulnerabilities. For the homeless populations, the loss of social community services and damages to shelters could add to protracted relocations. For the young and mobile populations who rent, the major disruption to housing, jobs and transit will also drive relocation. Widespread housing damage and preexisting housing market constraints will make it “extremely challenging” for the socially and economically vulnerable populations to find alternative housing near their home communities. Those who utilize interim and irregular housing for months and years after a disaster are more vulnerable to physical, social, and mental disorders, including suicide, substance abuse, and physical and verbal abuse. Aftershocks and post disaster conditions delay population return and increase outmigration.¹⁹²

**Erosion**

Risk from erosion relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Landslides**

Although infrastructural losses are of secondary importance to the risk to humans themselves, research investigating the vulnerability of people to landslides is rare. The many reasons for this lack of data are related to the fact that the collapse of occupied buildings which makes it a function of structural vulnerability and therefore, indirect. The degree of vulnerability to landslides by an individual considered at high risk, or even the general populations, also depends on human behavior, including many of the traditional social factors that are difficult to measure such as situational awareness, prior knowledge of hazards, and decision-making capabilities.\(^{193}\)

Landslides can result in primary lifeline failures through the loss of roads or power and communication lines. Transportation routes are often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods. Risk from landslide relates to earthen and infrastructural losses. The degree of vulnerability to these events and their impacts depends on human behavior and the traditional social factors such as situational awareness, prior knowledge of hazards, social capital and decision-making capabilities, as well as increased vulnerability due to social factors, such as racial and economic disparities.

**Power Outage/Public Safety Power Shutdowns (PSPS)**

Loss of power creates economic hardship to a region experiencing regular PSPS events, such as those experienced throughout the state over the recent years. Many businesses close, including gas stations, grocery stores, and local retail establishments. These impacts may deeply impact students dependent on support jobs, as well impacting family members of campus staff and faculty. PSPS increases risks to the public due to inability to use medical devices, spoilage of food and medicines, and disruption to infrastructure, such as supply of clean water and electricity used to run home medical equipment, such as lift chairs and ventilators.

**Wildfire**

Increased wildfire threat occurs especially in the end of fall, when conditions are driest, but before the winter rains have come; an east-to-west wind gusts exacerbate fire risk. Wildfire threats have the concomitant threat of Public Safety Power Shutoffs (PSPS). And, in the case of an actual wildfire, danger exists both from fire and from the smoke. Recent wildfires have demonstrated that some demographics are disproportionately affected. Native Americans are six times more likely to be affected than white people. Blacks and Hispanic people are 50 percent more vulnerable. These values take into account the likelihood of a community being affected and the greater difficulty of that community to recover. These statistics reflect the lack of access to resources to pay for insurance, to

rebuild and recover, to implement fire safety measures, and to access other resources. Price gouging after a fire (such as documented in Sonoma County after the 2017 Tubbs Fire) further exacerbates the disparity. Furthermore, the disabled and the elderly are at particular risk from extreme wildfire conditions, as they are often not as able to effectively evacuate. Of the 85 people who died in the Camp Fire in Butte in 2018, 62 of them were at least 65 years old.

Smoke from wildfires creates a significant public health threat. Especially vulnerable are individuals who have heart or lung issues, such heart disease, lung disease or asthma. Those most vulnerable include the medically fragile, elderly and children. Air Quality Indexes track the level of the following: particulate matter, surface levels of ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide. All of these can cause respiratory distress and harm lungs.

The California Department of Public Health reports the increased public health risks, and risk indicators that include: heat-related ED visits, populations living in wildfire areas, adults with multiple chronic conditions, populations living in poverty, race/ethnicity, outdoor workers, public transit access, air conditioner ownership and tree canopy.

Hazard Mitigation and Emergency Management Planning

exploring campus social risks and vulnerabilities, as well as to inform and to enhance holistic emergency management and hazard mitigation decision making, planning processes and future adaptive risk management strategies. By including the social resilience factors, mitigation investments may move beyond standardized planning and regulations, structure and infrastructure projects, and natural systems protections to embrace a more expanded, customized emergency operations plan and an education and outreach program unique to the campus.

A more robust social resilience inquiry is strongly encouraged to develop an accurate picture, based on methodical and scientific research-based data. Such an effort would be envisioned through both nuanced discussions with a variety of campus stakeholders and the invitation of nontraditional stakeholders to join in a collaborative resilience

partnership. Such a forward-leaning effort would be directly in keeping with CSU’s commitment to inclusion and equity in risk reduction.

8.1 University Profile

University History

California State University, East Bay (CSU East Bay) was founded in 1959 as Alameda State College. The school underwent several name changes until, in 1972, it earned university status and became CSU, Hayward. Its final name change came in 2005 after the school implemented a broader mission to serve the eastern San Francisco Bay Area. Today, the school includes four colleges and is classed as a Master's College and University by the Carnegie Institute. It is a federally recognized Hispanic-Serving Institution and from 2015-2017 was recognized by the Chronicle of Higher Education’s Almanac as the most diverse university in the mainland United States. CSU East Bay is designated as both a Hispanic-Serving Institution (HSI and an Asian American and Native American Pacific Islander-Serving Institution (AANAPISI).

University Governance

The campus president is the chief executive officer who oversees the administration of the entire university. The president manages campus operations and fundraising, sets campus priorities, and oversees the hiring and support of staff and faculty. The president also maintains a close working relationship with the CSU’s systemwide office, reporting to the chancellor and participating in the systemwide Executive Council.

The provost is the chief academic officer of the university, overseeing all academic affairs and programs of the university. The provost reports directly to the president.

The Academic Senate is made up of elected faculty members, administrators, staff members, and students who work together to determine policies and the Academic Calendar. The President and Provost are ex officio members. Six committees are included in the Senate, including three focused on academics, instruction, and research; one diversity and equity committee; one faculty affairs committee, and one budget and allocation committee.

University Mission

“Cal State East Bay welcomes and supports a diverse student body with academically rich, culturally relevant learning experiences which prepare students to apply their education to meaningful lifework, and to be socially responsible contributors to society. Through its educational programs and activities, the university strives to meet the educational needs and to contribute to the vitality of the East Bay, the state, the nation, and global communities.”

In addition to an academic plan, adopted in 2008 to highlight educational needs, priorities, and goals, the university has also implemented a diversity plan. The actions outlined in both plans are consistent with the university’s strategic goals around academic quality, inclusivity, community engagement, transparency, sustainability, social responsibility, and innovation.
University Location

CSU East Bay consists of three campuses: Hayward Hills, Concord, and Oakland Professional Development and Conference Center. The main campus is situated in the city of Hayward, a city of 159,000, just east of the Hayward fault. Located fewer than 20 miles south of Oakland, the area is characterized by a large number of manufacturing companies, including corporate headquarters, plants, and high-tech companies.

The city of Concord, 22 miles east of Oakland, is home to 122,000 people. It is largely a bedroom community for San Francisco and Oakland.

University Population

CSU East Bay typically enrolls approximately 15,000 students per semester. In fall 2019, the 14,705-student population was overwhelmingly made up of undergraduate degree seekers and female students. Latinx students made up 37.1% of all students, with Asian students making up the second most populous group at 22.6%.

In addition to the student population, the University is home to 1,763 faculty and staff.

8.2 Interim Final Rule for Hazard Vulnerability and Risk Assessment

Requirement §201.6(c)(2): The plan shall include a risk assessment that provides the factual basis for activities proposed in the strategy to reduce losses from identified hazards. Local risk assessments must provide sufficient information to enable the jurisdiction to identify and prioritize appropriate mitigation actions to reduce losses from identified hazards.

Requirement §201.6(c)(2)(i): [The risk assessment shall include a] description of the type...location and extent of all natural hazards that can affect the jurisdiction. The plan shall include information on previous occurrences of hazard events and on the probability of future hazard events.

Requirement §201.6(c)(2)(ii): [The risk assessment shall include a] description of the jurisdiction’s vulnerability to the hazards described in paragraph (c)(2)(i) of this section. This description shall include an overall summary of each hazard and its impact on the community.

Requirement §201.6(c)(2)(ii): [The risk assessment] must also address National Flood Insurance Program (NFIP) insured structures that have been repetitively damaged floods.

Requirement §201.6(c)(2)(ii)(A): The plan should describe vulnerability in terms of the types and numbers of existing and future buildings, infrastructure, and critical facilities located in the identified hazard area.

Requirement §201.6(c)(2)(ii)(B): [The plan should describe vulnerability in terms of an] estimate of the potential dollar losses to vulnerable structures identified in paragraph (c)(2)(ii)(A) of this section and a description of the methodology used to prepare the
estimating ..

**Requirement §201.6(c)(2)(ii)(C):** [The plan should describe vulnerability in terms of] providing a general description of land uses and development trends within the community so that mitigation options can be considered in future land use decisions.

**Requirement §201.6(c)(2)(iii):** For multi-jurisdictional plans, the risk assessment must assess each jurisdiction's risks where they vary from the risks facing the entire planning area.

### 8.3 Hazard Identification and Risk Assessment

#### Overview of California State University, East Bay History of Hazards

Numerous federal agencies maintain a variety of records regarding losses associated with hazards. Unfortunately, no single source is considered to offer a definitive accounting of all losses. The Federal Emergency Management Agency (FEMA) maintains records on federal expenditures associated with declared major disasters. The US Army Corps of Engineers (USACE) and the Natural Resources Conservation Service (NRCS) collect data on losses during the course of some of their ongoing projects and studies. Additionally, the National Oceanic and Atmospheric Administration’s (NOAA) National Centers for Environmental Information (NCEI) database collects and maintains data about natural hazards in summary format. The data includes occurrences, dates, injuries, deaths, and estimated costs. Many of these databases and other data collection services, including the NCEI, have inherent data limitations when searching for information at a university scale.

The best available data and records were used throughout this assessment.

#### Hazard Identification

As part of the initial hazard identification process, the Campus Assessment Team considered potential hazards with the most chance to significantly affect the planning area. The hazards include those that have occurred in the past and may occur in the future. A variety of sources were used to develop the list of hazards considered including national, regional, and local sources such as emergency operations plans, FEMA’s *How-To Series*, websites, published documents, databases, and maps, as well as discussion among the Campus Assessment Team members.

In the initial phase of the planning process, the Campus Assessment Team considered XX hazards and the risks they create for the University and its material assets, population, and operations. The hazards initially considered, and the determinations as to the treatment of those hazards, are shown in Table 8-1 (following).

**Future Occurrence Probability**

In order to determine the probability of future occurrences of each hazard profiled, the following scale was developed:

Highly Likely- 76%-100% that the hazard would occur annually.
Likely- 50%-75% that the hazard would occur annually.
Possible- 11%-49% that the hazard would occur each annually.
Unlikely- 0%-10% that the hazard would occur each annually.
Communicable Disease

Description of the Hazard

Communicable diseases are illnesses that occur due to infectious agents or their toxic products and are infectious due to their potential of transmission from one person or species to another by a replicating agent.¹ They may be transmitted from a reservoir to a susceptible host either directly as from an infected person or animal or indirectly through the agency of an intermediate plant or animal host, vector, or the inanimate environment. Communicable diseases are clinically evident illness resulting from the presence of pathogenic microbial agents, including pathogenic viruses, pathogenic bacteria, fungi, protozoa, multi-cellular parasites, and aberrant proteins known as prions.² The degree of spread of a communicable disease depends on both the ability of an organism to enter, survive and multiply in the host and the comparative ease with which the disease is transmitted to other hosts.³

Some ways in which communicable diseases spread are by:

- travel through the air, such as tuberculosis, measles, or COVID-19;
- physical contact with an infected person, such as through touch (staphylococcus), sexual intercourse (gonorrhea, HIV), fecal/oral transmission (hepatitis A), or droplets (influenza, TB, COVID-19);
- contact with a contaminated surface or object (Norwalk virus), food (salmonella, E. coli), blood (HIV, hepatitis B), or water (cholera); and,
- bites from insects or animals capable of transmitting the disease (mosquito: malaria and yellow fever; flea: plague).⁴

Collectively, the twenty-three (23) campuses and Chancellor’s Office of the California State University (CSU) system have identified nine (9) communicable disease hazards that have had significant impacts on their respective student, faculty, and staff populations. Of these communicable diseases, COVID-19 is considered to be the most prominent and widespread agent across all CSU campuses. (See Table 8-2 below.)

With the exception of COVID-19, there is variability among CSU campuses regarding which communicable diseases have had the greatest impact on individual campus communities. Table 8-3 shows the communicable disease hazards that have had the greatest impact on each CSU campus.

Descriptions of Identified Communicable Disease Hazards at CSU East Bay

CSU East Bay has identified two (2) communicable disease hazards that have had the greatest impact on campus – COVID-19 and Meningitis. The following are brief descriptions of the communicable disease hazards at CSU East Bay.

COVID-19 (SARS-CoV-2)

Coronaviruses are a family of viruses that can cause illnesses such as the common cold, severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS). In 2019, a new coronavirus was identified as the cause of a disease outbreak that originated in China. This virus is now known as the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease it causes is called Coronavirus Disease 2019 (COVID-19). In March 2020, the World Health Organization (WHO) declared the COVID-19 outbreak a pandemic.
Signs and symptoms of coronavirus disease 2019 (i.e., COVID-19) may appear two to 14 days after exposure. Common signs and symptoms can include fever, cough, and tiredness. Early symptoms of COVID-19 may also include a loss of taste or smell.

The virus that causes COVID-19 spreads easily among people, and more continues to be discovered over time about how it spreads. Data has shown that the COVID-19 virus spreads mainly from person to person among those in close contact (within about 6 feet, or 2 meters). The virus is transmitted by respiratory droplets being released when someone with the virus coughs, sneezes, breathes, sings or talks. These droplets can be inhaled or land in the mouth, nose or eyes of a person nearby. In some situations, the COVID-19 virus can spread by a person being exposed to small droplets or aerosols that stay in the air for several minutes or hours (i.e., airborne transmission). It's not yet known how common it is for the virus to spread this way. The COVID-19 virus can also spread if a person touches a surface or object with the virus on it and then touches his or her mouth, nose or eyes; however, this is not considered to be a main way it spreads.

The severity of COVID-19 symptoms can range from very mild to severe. Some people may have only a few symptoms, and some people may have no symptoms at all. However, some people may experience worsened symptoms, such as worsened shortness of breath and pneumonia. People who are older have a higher risk of serious illness from COVID-19, and the risk increases with age. People who have existing medical conditions also may have a higher risk of serious illness from COVID-19. In some cases, the disease can cause severe medical complications and may even lead to death.⁵

**Meningitis**

Meningitis is an inflammation of the fluid and membranes (meninges) surrounding the brain and spinal cord. The swelling from meningitis typically triggers signs and symptoms such as headache, fever and a stiff neck. Early meningitis symptoms may mimic the flu (influenza). Symptoms may develop over several hours or over a few days.

Most cases of meningitis in the United States are caused by a viral infection, but bacterial, parasitic and fungal infections are other causes. Some cases of meningitis improve without treatment in a few weeks. Others can be life-threatening and require emergency antibiotic treatment. Bacterial meningitis is particularly serious and can be fatal within days without prompt antibiotic treatment. Delayed treatment also increases the risk of permanent brain damage or death.⁶

**Location of the Hazard**

Communicable diseases have the potential to affect the entire CSU East Bay planning area equally. As a result, the communicable disease hazard can be found at the CSU East Bay (CSUEB) main campus located in Hayward, CA (Alameda County), at the CSUEB

---

satellite campus in Concord, CA (Contra Costa County) and at the CSUEB Oakland Professional Development and Conference Center. Because of the ubiquitous nature of many communicable diseases, students, faculty, staff at (and visitors to) all three (3) CSUEB locations are at risk of exposure to the communicable disease hazard.\(^7\)

**CSU Student Housing Locations and Populations**

Although CSU-campus-owned student housing opportunities have been severely limited due to the COVID-19 pandemic, this situation is temporary. Eventually, students will be allowed back on campus at full capacity, and many of these students will be living in campus-owned housing. When this occurs, over 53,000 students (i.e., just over 11\% of the CSU total enrollment) will be at increased risk of exposure to communicable disease hazards, owing to the “close-quarters” living arrangements in student housing. For CSU – East Bay, approximately 15\% of its 14,705 enrolled students or 2,206 students reside in student housing. Table 8-4 shows the number of students that were living in CSU-campus-owned housing in Fall 2019, prior to the COVID-19 pandemic.\(^8\),\(^9\)

### Extent of the Hazard

Various communicable diseases are categorized by the Center for Disease Control and Prevention (CDC) by levels of containment called Biosafety Levels (or BSLs). The higher the BSL, the greater the level of containment and level of effort necessary to prevent transmission of the disease, and therefore the greater the hazard.

Biosafety Levels prescribe procedures and levels of containment for a particular microorganism or material (including research involving recombinant or synthetic nucleic acid molecules) and procedures associated with that containment. BSLs also consider primary barriers (e.g., biosafety cabinets), secondary barriers, facility design, air handling, laboratory security, etc. BSLs are graded from 1 to 4; as the BSL increases so does the relative risk of the agent/procedures as well the stringency of procedures and facility design.

---

Figure 8-1 describes the different BSLs and provides examples of communicable diseases that would typically fall into these classifications, as well as the typical protections that would be necessary to prevent transmission of each of the diseases.

Figure 8-1: Biosafety Levels (BSLs)\textsuperscript{13}

The Extent of CSU East Bay Communicable Disease Hazards Except COVID-19:
Before the COVID-19 pandemic, there were cases of Meningitis at CSU East Bay. Meningitis would be classified at the BSL-2 containment level.\textsuperscript{14}

The Extent of CSU East Bay COVID-19 Communicable Disease Hazard:
As a microorganism, the SARS-CoV-2 (COVID-19) virus requires a high level of containment. It is therefore classified at BSL-3.\textsuperscript{15}

History of the Hazard
Over an approximately one-year period, from mid-March 2020 to March 23, 2021, there were a reported 29 cases of COVID-19 at CSU East Bay. CSU-campus-specific COVID-19 case data for CSU East Bay can be found in the “History of the Hazard” section below.

Each CSU campus is an integral part of the surrounding community. Any event that occurs on a CSU campus has an effect on both the adjacent areas of campus and on the community-at-large – and vice-versa. Communicable disease hazard events are no exception. Most communicable disease data are maintained by at the state and at the county levels and are not generally available at the municipal or campus levels, unless (a) the CSU campus falls under the jurisdiction of a city-level health department, or (b) a geographically specific outbreak occurs on campus or in the local community. The exception to this is the current COVID-19 pandemic, where both campus and County-level case data have been collected. As a result, it is important to provide COVID-19 case statistics for both CSU campuses and the counties where CSU campus assets are located.

Tables 8-5 and 8-6 show county-level COVID-19 Case data for CSU East Bay. These case data are updated on at least a weekly basis. (Please note that the COVID-19 case numbers here may not reflect the most recent updates.)

Potential Impacts of the Hazard

Communicable disease outbreaks and pandemics potentially have (and will continue to have) direct impact on life, health, and safety across the CSU system (including the CSU – East Bay campus). The extent of this impact is contingent on the type of infection or contagion, the severity of the outbreak, and the speed at which it is transmitted. Property and infrastructure integrity may be affected if large portions of the campus population contract communicable diseases at the same time and are therefore unable to perform maintenance, operations, and educational tasks. This would be particularly disruptive if those impacted are first responders or other essential personnel. Long-term outbreaks affecting large numbers of CSU – East Bay students could result in cancelled classes, delayed matriculation, or other disruptions to the CSU System’s mission. This has already occurred with the current COVID-19 pandemic, and could occur again with more virulent strains of communicable diseases, including COVID-19.

Communicable disease hazards found across the CSU system (including CSU – East Bay) vary both by level of containment (BSL) (described previously) and by level of individual/public health risk, or Risk Group (RG) level. While BSLs describe the procedures and required levels of containment in a laboratory setting, Risk Groups (RGs) reflect the potential effects of disease exposure on humans or animals. Like BSLs, RGs range from Level 1 (RG1) to Level 4 (RG4), with Level 1 (RG1) posing minimal risk to healthy individuals and public health and Level 4 (RG4) posing a very serious or extreme risks to individuals and public. BSLs generally correlate with Risk Group (RG) Levels (e.g., a RG2 agent is worked with at BSL-2), but there are exceptions (e.g., production volumes, high-risk procedures, etc.).

The World Health Organization’s (WHO) Laboratory Biosafety Manual, 3rd ed., NIH Guidelines, categorizes Risk Groups (RGs) in the following way:

Table 8-7: WHO Risk Group Categorization

<table>
<thead>
<tr>
<th>Risk Group (RG)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG1</td>
<td>Rarely associated with disease in healthy adult humans or animals and pose no-to-little public health risk (e.g.,</td>
</tr>
</tbody>
</table>

---

Saccharomyces cerevisiae, E. coli K-12 strain derivatives often used for recombinant/molecular biology, many environmental organisms

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>RG2</td>
<td>Associated with mild to moderate disease for which preventative measures or post exposure treatments are often available; public health impact is limited (e.g., Streptococcus pyogenes, Salmonella, hepatitis B virus)</td>
<td></td>
</tr>
<tr>
<td>RG3</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post-exposure therapies may be scarce. Public health impact is limited-to-moderate (e.g., Mycobacterium tuberculosis, hantaviruses, West Nile virus, SARS)</td>
<td></td>
</tr>
<tr>
<td>RG4</td>
<td>Associated with serious to lethal human disease for which preventative vaccines or post exposure therapies are not usually available. Public health impact is high (e.g., Ebola virus, Marburg virus, smallpox virus, etc.)</td>
<td></td>
</tr>
</tbody>
</table>

Table 6-7 describes the four (4) Risk Group Levels (RGs), and provides examples of communicable diseases that would typically fall in to these classifications, and the typical protections that would be necessary to prevent transmission of the disease. It is important to note that all but two (2) communicable disease hazards identified by CSU campuses fall under either the lower-risk RG1 or RG2 categories. COVID-19 and tuberculosis are the two (2) communicable diseases fall under the higher-risk RG3 category. However, with the advent of the recently-developed COVID-19 vaccine, and with the expectation of an increasingly robust vaccine supply, it is possible that the RG level for COVID-19 could be lowered in the future, thereby reducing both the extent and the potential impact of COVID-19.

Table 8-8: Risk Group Levels (RGs) with Example Diseases and Recommended Precautions

<table>
<thead>
<tr>
<th>Level</th>
<th>Examples</th>
<th>Typical Protection to Prevent Transmission</th>
</tr>
</thead>
<tbody>
<tr>
<td>Risk Group Level I</td>
<td>E. Coli</td>
<td>Precautions are minimal, most likely involving gloves and some sort of facial protection. Usually, contaminated materials are left in open (but separately indicated) waste receptacles. Decontamination procedures for this level are similar in most respects to modern precautions against everyday viruses (i.e.: washing one’s hands</td>
</tr>
</tbody>
</table>

Risk Group Level II

<table>
<thead>
<tr>
<th>Chicken Pox</th>
<th>Hepatitis A, B, C</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lyme disease</td>
<td>Salmonella</td>
</tr>
<tr>
<td>Mumps</td>
<td>Measles</td>
</tr>
<tr>
<td>Malaria</td>
<td>Scrapie</td>
</tr>
<tr>
<td>Dengue Fever</td>
<td>HIV</td>
</tr>
</tbody>
</table>

These bacteria and viruses cause mild disease in humans or are difficult to contract via aerosol. Routine diagnostic work with clinical specimens can be done safely at BSL-2, using BSL-2 practices and procedures.

Risk Group Level III

<table>
<thead>
<tr>
<th>Anthrax</th>
<th>West Nile Virus</th>
</tr>
</thead>
<tbody>
<tr>
<td>SARS Virus (Including COVID-19)</td>
<td>Tuberculosis</td>
</tr>
<tr>
<td>Typhus</td>
<td>Yellow Fever</td>
</tr>
<tr>
<td>Hantaviruses</td>
<td>Avian Flu</td>
</tr>
</tbody>
</table>

These bacteria and viruses cause severe to fatal disease in human, but vaccines or other treatments do exist to combat them. Laboratory personnel have specific training in handling pathogenic and potentially lethal agents and are supervised by competent scientists who are experienced in working with these agents. This is considered a neutral or warm zone.

Risk Group Level IV

<table>
<thead>
<tr>
<th>H5N1 (Bird Flu)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dengue Hemorrhagic Fever</td>
</tr>
<tr>
<td>Marburg Virus</td>
</tr>
<tr>
<td>Ebola Virus</td>
</tr>
<tr>
<td>Smallpox</td>
</tr>
</tbody>
</table>

These viruses and bacteria cause severe to fatal disease in humans, for which vaccines or other treatments are not available. When dealing with biological hazards at this level the use of a Hazmat suit and a self-contained oxygen supply is mandatory. The entrance and exit of a BSL-4 lab will contain multiple showers, a vacuum room, an ultraviolet light room, autonomous detection system, and...
other safety precautions designed to destroy all traces of the biohazard. Multiple airlocks are employed and are electronically secured to prevent both doors opening at the same time. All air and water service going to and coming from a BSL- 4 lab will undergo similar decontamination procedures to eliminate the possibility of an accidental release.

Probability of Future Occurrence of the Hazard

There are significant data limitations regarding non-COVID-19 communicable disease cases, as the information thereof is outdated, anecdotal, and/or inadequate. As a result, it is not feasible to provide quantitative probabilities of future occurrence for non-COVID-19 communicable disease hazards. However, based on the limited data, it is feasible to present qualitative probabilities of future occurrence based on ranges of communicable disease frequency.

Table 8-9 shows a probability scale of future occurrence for the nine (9) communicable disease hazards profiled in this assessment. This scale is divided into four (4) levels of probability:

Table 8-9: Likelihood of Future Hazard Occurrence

<table>
<thead>
<tr>
<th>Likelihood</th>
<th>Parameters for Determining Likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highly Likely</td>
<td>76 – 100% probability that hazard will occur annually (high to very high frequency)</td>
</tr>
<tr>
<td>Likely</td>
<td>50 – 75% probability that hazard will occur annually (moderate to high frequency)</td>
</tr>
<tr>
<td>Possible</td>
<td>11 – 49% probability that hazard will occur annually (low to moderate frequency)</td>
</tr>
<tr>
<td>Unlikely</td>
<td>0 – 10% probability that hazard will occur annually (very low to low frequency)</td>
</tr>
</tbody>
</table>

Due to significant data limitations surrounding non-COVID communicable diseases, the probability of future occurrence of CSU-system-wide communicable disease is measured by the proportion of campuses that have identified a particular communicable disease as having an impact on the campus community. In this measure, the more frequent a communicable disease is seen as impactful CSU-wide, the greater the probability of future occurrence.

Note: Each communicable disease’s system-wide probability ranking (below) reflects the ranking at the individual CSU campus level unless noted otherwise.

(Source: Interviews with staff at CSU campuses and at the CSU Chancellor’s Office.)

Vulnerability to the Hazard

Vulnerability to a communicable diseases hazard resides in the population of a given area – both human and animal – not in the infrastructure or physical assets. While CSU assets and infrastructure could be impacted indirectly by the communicable disease hazard, these impacts would be secondary to the impact that the communicable disease hazard would have on students, faculty, staff, and visitors at the CSU – East Bay campus.

CSU campus settings are geographically diverse, with locations ranging from small towns to medium-sized cities to densely populated urban areas. Hundreds of thousands of people work, study, and/or pass through CSU campuses on any given day. (As of Fall
2019, the CSU System had 480,541 students and 53,763 faculty and staff. Each of these persons is vulnerable to communicable disease, particularly if it is a pathogen that individual has not been immunized against, or for which no immunization exists. Prolonged outbreaks could result in a loss of services, failure of infrastructure (from lack of operators or maintenance), and closure of facilities. This exact scenario has played out to some degree in the current COVID-19 pandemic on the CSU – East Bay campus.

Estimate of Potential Losses

COVID-19 Pandemic Health Impact on CSU Campuses and Surrounding Communities

The most prescient metric for estimating losses from COVID-19 is loss of life. The nationwide campus-related COVID-19 death rate of 0.02% remains well below the average COVID-19 death rate in the U.S. However, due to data limitations, there is no information on CSU-campus-specific deaths by COVID-19 or by any other communicable diseases. In fact, COVID-19 is the only communicable disease for which case reports have been readily available for CSU campuses.

At some point in the future, CSU campuses will return to full capacity. Without adequate surveillance regarding campus access and student and employee interaction, CSU campuses (including CSU – East Bay) are at risk of developing an extreme incidence of COVID-19, and may become “super-spreaders” for adjacent communities. The emergence of more virulent COVID-19 variants would only add to the potential for high negative impacts on life safety, operations, and service delivery across the CSU system. (Other communicable diseases would also re-emerge, but with low to moderate negative impacts on life safety, operations, and service delivery.)

Economic Impact of COVID-19 Pandemic on CSU Financial Health

During the first few months of the COVID-19 pandemic in 2020, the CSU system suffered tremendous negative fiscal impacts. From March through July of 2020 alone, over $146 million worth of revenue losses were sustained across the CSU system due to refunds to students for parking, housing and dining service fees during Spring Semester, 2020. See Table 8-11 below for the economic impact to CSU – East Bay.

---

22 The California State University. Enrollment. Retrieved 05.03.2021 from: https://www2.calstate.edu/csu-system/about-the-csu/facts-about-the-csu/enrollment/Pages/default.aspx

Mitigative Relief from Federal Assistance

The $1.5 billion in total federal assistance sent to the CSU system will help relieve the losses of revenues from services like dorms, parking and dining services during a year of mainly empty campuses. (See Table 8-12) However, because of staggering COVID-related revenue losses, the CSU system is planning for three (3) years of fiscal duress.

8-22
Vulnerability Assessment Conclusions

Before the COVID-19 pandemic, populations at all CSU campuses and CSU-affiliated facilities were substantial. Collectively, as of Fall 2019, CSU campuses had 480,541 students and 53,763 faculty and staff. All were at risk from the communicable disease events, with 534,304 people being directly vulnerable. The COVID-19 pandemic has caused campus population numbers to plummet to a small fraction of full capacity.

At some point in the future, campus population numbers will return to their pre-pandemic levels, and students, faculty, and staff will again be vulnerable to the communicable disease hazard. If just 10% of the total CSU population were to become ill with a highly infective communicable disease like influenza or another strain of SARS, this would mean that approximately 53,430 people would be sick at the same time. This scenario would likely overwhelm available on-campus medical services could even overwhelm portions of the larger community’s medical resources – especially if there were large numbers of infected people with immune system compromises or other underlying health problems. See Table 8-13 below for the “10% outbreak scenario” projections for the CSU – East Bay campus and for the entire CSU system.

Note: Enrollment figures do not include non-specific CSU campus International Programs (455 students) or CALStateTEACH Program (933 students).

While the case numbers of COVID-19 have been significantly lower (about 1% of the total CSU population) than those in the 10% scenario, the degree of virulence and resultant morbidity and mortality caused by COVID-19 have led to widespread campus shutdowns, educational disruption, and economic harm to the CSU system. In short, the real-time COVID-19 communicable disease outbreak scenario has proven far more devastating than the 10% simulated scenario.
Identified Data Limitations

There is a wealth of technical information available for communicable disease. However, there is also limited non-COVID-19 communicable disease data available regarding risk or vulnerability of specific populations throughout the CSU. Much of the data that does exist is protected by privacy policies, and therefore cannot be obtained for more specific populations. As a result, performing a detailed quantitative assessment for this hazard is difficult.

Data that could be collected prior to the next update in order to improve this methodology includes:

Data regarding infection rates at the campus level and for specific populations;
Data regarding communicable disease case numbers and outcomes, by CSU campus;
Data regarding projected population changes;
Data regarding absenteeism; and
Data regarding increased operating costs as a result of absenteeism (i.e., temporary shifting of duties resulting in business interruption).
**Dam and Levee Failure**

**Description of the Hazard**

A dam failure represents the structural collapse of a dam that stores water in a reservoir behind the dam. These failures are typically the result of structural age, damage to the structure caused by earthquake or flooding, inadequate discharge or spillway capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the reservoir. Prolonged precipitation may result in overtopping of the dam resulting in structural compromise. The tremendous energy generated by a sudden breach of the dam will have significant downstream effects. Flood damage resulting from dam failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties. This type of incident is extremely dangerous as it can occur rapidly, with no warning resulting in an inability to effectively evacuate threatened communities.

A levee failure is similar to dam failures as the result will be a breach causing flooding on the dry side of the levee. Levees are embankments whose primary purpose is to furnish flood protection from seasonal high water or divert the flow of water. Most levees in California are intended to withstand peak water levels generated by heavy precipitation or rapid snowmelt in a watershed. Other levees are designed to withstand fluctuating water levels on a continuous basis such as those in the California Delta exposed to tidal influences. Levees routinely extend for lengthy distances immediately protecting communities. Levees can be found throughout the state but are most prominent in the Sacramento and San Joaquin Valleys.

Levee failures can vary from overtopping to small uncontrolled discharge to catastrophic failure. Areas downstream of the failure will be subject to inundation dependent on the volume of water released. These levee failures are also typically the result of structural age, damage to the structure caused by earthquake or flooding, slumping, seepage underneath the levee, high velocity flows eroding the levee, inadequate capacity, inadequate maintenance, improper construction materials, or extreme inflow of water into the system. Flood damage resulting from levee failures potentially will result in economic losses, environmental damage, destruction of agriculture, and human casualties.

A Dam or levee failure flooding will vary depending on a number of factors including the extent of the collapse or breach, the volume of water behind the structure, and the nature of the exposed downstream features. This unpredictable flooding presents a threat to life and property in addition to critical infrastructure. Lifelines and supply routes will likely be damaged or made impassible by flood erosion or standing water. Water quality and health concerns would likely be cascading effects of dam or levee failures.

---

Location of the Hazard

Alameda County is home to a variety of flood control facilities and levee systems mostly throughout the Oakland and Hayward Hills and along the San Francisco Bay. Dams are located in various valleys throughout the hills and along the base of the hills where drainage meets populated areas. Levees have been constructed along various flood control channels and in protection against tidal influences providing community protection.

The closest dam facility in proximity to CSU East Bay is the Ward Creek dam. This facility is an earthen dam that has a capacity of holding 117af of water. The dam sits in a valley ¾ mile north of the campus. The height of the dam is lower in elevation than the campus and discharges its water to the west away from the campus. There are no other dam facilities that are in proximity to the campus.

There are other Alameda County dams that may have indirect effects to the CSU East Bay campus. The James H Turner Dam holding the San Antonio Reservoir is 13 miles to the southeast of the campus. The Calaveras Dam and Reservoir is 17 miles southeast of the campus. A failure of these dams would likely cause significant disruptions across multiple transportation routes in Hayward, Fremont, and Union City. Interstates 680 and 880 in addition to surface streets in these cities reside within the inundation zone.

The Alameda Creek drains the hills of the East Bay and the San Antonio Reservoir. The length of the Alameda Creek from the base of the hills in Fremont to the outlet into the San Francisco Bay is a levee protected flood control channel. The channel is located almost 4.5 miles south of the CSU East Bay campus and is lower in elevation than the campus. However, the creek crosses into populated communities that would support transportation access to the campus from the south and support resources within these communities.

Additional levees are found along the San Francisco Bay providing protection against tidal influences. These levees serve a direct protection role to parts of Hayward, Fremont, and Union City but are not providing a direct role in protecting the campus. The campus is situated in the hills elevated from tidal influences. However, the campus transportation access, access to affected support services, and impacts to the campus community residing or working in these areas may be threatened.
Extent of the Hazard

Dams are classified according to the hazard that they pose to life and property in the event of failure, rather than the likelihood of that failure.

**High hazard potential dams** may result in loss of human life, and will likely result in economic, environmental, or lifeline losses.

**Significant hazard potential dams** are not expected to result in loss of life, but are expected to cause economic, environmental, and lifeline losses.

**Low hazard potential dams** are not expected to result in loss of life, and there is a low expectation of economic, environmental, or lifeline losses. What losses do occur are generally limited to the dam owner.

Dams classified as high hazard are required to have Emergency Action Plans (EAP). EAPS are formal documents that identify potential emergency conditions at the dam and
specify preplanned actions to be followed in case of failure. An EAP is required for all high hazard dams and is recommended for all significant hazard dams.

<td>High Hazard</td>
</tr>
</tbody>
</table>

The CSU East Bay campus lies outside of the inundation zone of the dams listed above. In the event of a catastrophic failure of the identified dams, the CSU East Bay campus is expected to remain out of the inundation area. The inundation area is expected to spread water in areas below the elevation of the campus. However, there are multiple transportation corridors that lie within the dam inundation zones that could compromise transportation routes and areas the campus community reside or work. Based on these conditions, the planning committee ranks the extent of the dam failure hazard as **Low**.

---

Figure 8-3: New Calaveras Dam Breach Inundation Map

Extent – Levee Failure

Levees are used along numerous flood control channels and other waterways including the Los Angeles River, Dominguez Channel, and Compton Creek. The CSU East Bay campus lies outside of the levee flood protected areas for these levees. As such, it is not at risk to direct levee failure impacts. In the event that any of these channels were flowing at elevated levels and a failure of a levee were to occur, the communities lying within the protection zone of the failed levee would likely experience flood related damages. Based on these factors, the planning committee ranks the extent of the hazard as Low.

History of the Hazard

34 California Department of Water Resources. *Dam Breach Inundation Map Publisher*. Retrieved 04.08.2021 from: https://fmds.water.ca.gov/webgis/?appid=dam_prototype_v2
There are no records of dam or levee failures in areas that present a threat to the CSU East Bay campus. Alameda County has experienced the following dam failures:

Potential Impacts of the Hazard

**Dam Failure Impacts**

Water that is released due to a dam that has failed generates tremendous energy and force causing a flood that will be catastrophic to life and property. Water levels from the failed dam could be significantly higher than those experienced in worst case scenario flood events. Areas closer to the failed dam will be more likely to experience complete devastation while other areas within the inundation zone will see varying levels of flood waters. The extent of the impacts of a failed dam would vary based on a number of factors such as the volume of water released, the base flow of the river, the time of the failure, the amount of warning provided, and the distance from the dam. Impacts resulting from a dam failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Floods generating threats to public health
- Flood generated debris
- Damage or destruction of academic materials, fine arts, and research

Levee Failure Impacts

A levee failure may result in substantial amounts of water to enter into developed areas protected by the levee. The force and volume of water that is generated by a levee failure may cause extensive structural damage in close proximity to the breach and effects of flooding spreading well beyond the point of the failure. The extent of the impacts would vary based on a number of factors such as the volume of water released, the time of the failure, the amount of warning provided, the location of the breach, elevation, and distance from the breach. Potential impacts resulting from a levee failure include:

- Loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Disruptions to education delivery to community
- Damage or destruction of academic materials, fine arts, and research
- Damage or destruction of university computer systems and networks
- Damaged university infrastructure
- Reduced or eliminated student engagement with academic programs
- Reductions in campus revenues

Probability of Future Occurrence of the Hazard
Alameda County is determined to be at risk from dam and levee failure. However, the location of the CSU East Bay campus elevated in the hills east of Hayward minimizes exposure to Alameda County dams or levees. The campus is located outside of identified dam or levee inundation zones. There are no official recurrence intervals that have been calculated for dam or levee failures. However, based on no historical occurrences, the likelihood of this hazard is low.

The probability of future occurrence for both dam and levee failures is Unlikely.

Vulnerability to the Hazard

The CSU East Bay campus is subject indirectly to the effects of flooding resulting from compromised dams and levees. The effects would likely be mostly affecting members of the campus community and regional transportation networks and services. The flood control channels are lined by levees intended to protect the surrounding areas from rises in water level. In the case of dam failure, the amount of time to respond to the needs of the campus community will be limited.

Any breach along a levee is impossible to predict where a failure may occur. It is likely that response action will not be fully implemented until the incident situational intelligence provides adequate information as to compromised locations. These variables place all those working and living within the dam inundation and flood protection zones in vulnerable locations.

The distributed placement of levees, most near development may expose significant vulnerabilities to other areas of the region even if the campus is unaffected. There is potential the campus community will be affected as a breach may cause flooding and damages to the homes of students, faculty, and staff or to access/supply routes, utilities, or other critical services. The potential for flood damaged structures being left uninhabitable including campus residence halls will result in the vulnerability of numerous displaced individuals and households. The lack of flood insurance will cause additional extreme financial burdens on those affected.

Vulnerability to the secondary or indirect effects of a dam or levee failure on the CSU East Bay campus will vary depending on the extent of the breach or structural failure and when the failure were to occur, and will be lessened during periods when classes are not in session or during periods of breaks. Conversely, during the days and hours that classes are in session and staff are at their workplaces, the vulnerability increases. However, in region-wide events this vulnerability may be shared with the homes and workplaces of members of the campus community and their families.

Certain campus populations will experience greater challenges to a post-flood / failure environment. Vulnerable populations will likely need to navigate through flood generated debris, face extreme health safety issues from flood waters, experience extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

Estimate of Potential Losses
Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The proximity to the failure and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the failure was to occur will influence the number of people on campus and potential casualties. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the total replacement costs due to earthquake are $164,768,550. However, it is unlikely for a dam or levee failure event to cause catastrophic destruction at CSU East Bay.

Vulnerability Assessment Conclusions

While the occurrence of dam and levee failures have not been historically relevant near the CSU East Bay campus, the potential for hazards related to the region’s levees and dams still exist. This hazard is associated with support systems and transportation corridors servicing the campus and effects to the campus community rather than a direct exposure to the campus locations. Additionally, the presence of earthquake faults in proximity to the existing dam and levee structures presents a valid danger to downstream locations in the event of an earthquake. In the unlikely event of a catastrophic dam failure, the consequences to downstream communities would be severe. The potential for dam or levee failure further generates the added potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

Identified Data Limitations

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation. Missing facility information of satellite campuses and locations.
**Drought**

**Description of the Hazard**

Drought is defined as a condition where moisture levels fall significantly below normal for an extended period of time over a large area that adversely affects plants, animal life, and humans. Drought is a gradual phenomenon. Although droughts are sometimes characterized as emergencies, they differ from typical emergency events. Most natural disasters, such as floods or forest fires, occur relatively rapidly and afford little time for preparing for disaster response. Droughts occur slowly, over a multi-year period, and it is often not obvious or easy to quantify when a drought begins and ends.

Throughout California, one dry year does not normally constitute a drought. California’s extensive system of water supply infrastructure (reservoirs, groundwater basins, and conveyance assets) mitigates the effect of short-term dry periods for most water users. Defining when a drought begins is a function of drought impacts to water users. Drought in one location may not constitute a drought for all water users, as some users in relative proximity may have a different water supply. For example, individual water suppliers may use a combination of sources such as rainfall/runoff, water in storage, or expected supply from a water wholesaler to define their water supply conditions.

Drought can be characterized as one or more of the four following types:

**Meteorological drought** is defined on the basis of the degree of dryness (in comparison to some “normal” or average amount) and the duration of the dry period. A meteorological drought must be considered as region-specific since the atmospheric conditions that result in deficiencies of precipitation are highly variable from region to region.

**Hydrological drought** is associated with the effects of periods of precipitation (including snowfall) shortfalls on surface or subsurface water supply (e.g., streamflow, reservoir and lake levels, ground water). The frequency and severity of hydrological drought is often defined on a watershed or river basin scale. Although all droughts originate with a deficiency of precipitation, hydrologists are more concerned with how this deficiency plays out through the hydrologic system. Hydrological droughts are usually out of phase with or lag the occurrence of meteorological and agricultural droughts. It takes longer for precipitation deficiencies to show up in components of the hydrological system such as soil moisture, streamflow, and ground water and reservoir levels. As a result, these impacts are out of phase with impacts in other economic sectors.

**Agricultural drought** focus is on soil moisture deficiencies, differences between actual and potential evaporation, reduced ground water or reservoir levels, and so forth. Plant water demand depends on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil.

**Socioeconomic drought** refers to when physical water shortage begins to affect health, well-being, and quality of life of people, or when the drought starts to affect the supply and demand of an economic product that relies on water.
The drought issue in California is further compounded by water rights. The central challenge is how to prioritize water usage among a broad variety of contexts. It is for this reason that water is a commodity possessed and utilized under a variety of legal doctrines. As such, many competing sets of interests create a dynamic prioritization process between, for example, farming and federally protected fish habitats and water supply for municipal/public use (including usage for CSU - East Bay) versus water usage for wildfire abatement or natural resource protection.

Location of the Hazard

Drought conditions have been identified in Alameda County and Contra Costa County where CSU - East Bay is located. Drought is not a location-specific hazard and affects the entire planning area equally. Drought location is not isolated to each campus footprint but occurs as a geographic sub-set of drought conditions occurring at larger scales. From 2000-2020, drought conditions existed continuously somewhere in the state, with 80-100% of the state impacted for 12 of the last 20 years.36

Extent of the Hazard

Given the historical occurrence of severe drought impacts throughout the CSU system-wide planning area and across the state and the potential future impact exacerbated by climate change, the CSU Planning Committee recognizes that drought will continue to pose a high degree of risk, potentially impacting crops, livestock, water resources, the natural environment at large, buildings and infrastructure (from land subsidence), and local economies. That said, although drought affects the entire planning area, the potential impacts may be variable and specific to each campus/jurisdiction, depending on contextual factors such as the degree of assets and activities historically impacted by drought within each jurisdiction. In addition, land subsidence has occurred state-wide and will continue in areas where the groundwater basin has been subject to overdraft and long-term recharge is inadequate to maintain the water table elevation, leaving underground voids. Subsidence levels have been measured up to 30-feet in California with subsidence bowls covering hundreds of square miles. As such, drought-related subsidence may result in serious structural damage to buildings, roads, irrigation ditches, underground utilities, and pipelines. Such effects, while not reported for the campus up to this point, are applicable concerns for the East Bay campus over the long term.37

The U.S. Drought Monitor developed tables of impacts reported during past droughts in California in order to depict the extent of drought risk for each level of drought on the U.S. These possible extent conditions for California complement the general impacts column of the U.S. Drought Monitor Classification Scheme.

**History of the Hazard**

Historically, drought has been so prevalent in California that its presence is almost continuous, including Alameda County which surrounds the CSU - East Bay footprint. According to the US Drought Monitor Time Series data, Alameda County has experienced eight (8) periods of drought covering 12 years from 2000-2021.
Although no data is available on campus-level drought occurrences, according to the National Drought Mitigation Center, over 3,500 reports and publications covering 370 drought-related events took place across the state (many of which were statewide events) between 2000-2020. In addition, the National Center for Environmental Information (NCEI) reports more than 500 events statewide during this same time period. These events produced a comprehensive range of impacts to water supply, regulations and allocations to businesses and municipalities, budgets and resources for firefighting, water law and policy, and physical impacts to built and natural environments. As such, data records of previous occurrences can be viewed as separate time and event demarcations for a hazard almost continuously in effect across the state with cascading impact potential.

According to the Department of Water Resources, droughts exceeding three years are relatively common in Southern California, but relatively rare in Northern California - the region is the geographic source of much of the state’s developed water supply. The 1929-34 drought established the criteria commonly used in designing storage capacity and yield of large Northern California reservoirs.

According to the US Drought Monitor’s time series data, from 2000-2021 (with the exception of a 2–3-month period in 2000 and 2011), some degree of drought conditions have been continuously in effect somewhere in California. In fact, 80% - 100% of the state has been subjected to drought conditions for 12 of the last 20 years, with the most severe drought being the 100% state-wide event from 2012-2017.

Given the extent of the drought risk in California, the following drought event was selected as an exemplar due to its broad and significant impacts on the state and on the region surrounding the CSU - East Bay campus planning area:

2012 – 2017 – Drought produced severe impacts to water wells throughout the state of California, with a high number of wells running dry. Land subsidence due to increased groundwater pumping also occurred in numerous areas of the state such as the San Joaquin and Central Valleys. Crop damage was widespread as well. Water allotments were drastically reduced in many towns and water agencies, with extremely high costs for procuring water. In addition, job loss occurred with many families requiring food supply assistance, and water supply assistance provided to home-owners with dry wells. According to a report released by UC Davis Center for Watershed Sciences, the 2014-2017 period of the California drought cost the state’s agriculture industry about $1 billion in lost revenue, with a total statewide economic cost of the drought calculated to be $2.2 billion.44 The report says, “it is responsible for the greatest water loss ever seen in California agriculture - about one third less than normal.” The report calls the groundwater situation in California "a slow-moving train wreck." Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since contributed to near-record low levels in the Shasta Reservoir. The ongoing drought has contributed to declines in crop values across the state. For example, crops including cotton, corn silage and barley (the field crop category) fell by 42 percent.45

Potential Impacts of the Hazard

Drought impacts are wide-reaching and may be economic, environmental, and/or societal. This assessment of its impact recognizes that historic occurrences of drought throughout the planning area are a sub-set of larger and inter-connected local and

---

regional droughts, and that the (related) historic impacts provide a sound basis for understanding potential (future) impacts.

Though no historic impacts are recorded for drought on campus, the most significant potential impact associated with drought across the CSU - East Bay campus planning area is the historic and potential reduction in water availability for the municipal area tied to each campus. Other impacts include crop loss and damage to trees and other natural resources (See Tree Mortality below). The footprint of CSU - East Bay to some extent includes these vulnerable resources based on the campus landscape (trees) and the presence (and footprint size) of agricultural research crops and field stations.

As a secondary impact of drought, wildfire is directly attributable to dry atmospheric conditions. Wildfires almost always coincide with drought in California, though not limited to such. However, the wildfire hazard is analyzed separately in this plan. See wildfire section towards the end of this section.

In reviewing the occurrences of drought for CSU - East Bay (in municipality and county), the US Drought Monitor and the National Drought Mitigation Center report that tens of millions of trees died during the (2014-2017) state-wide drought disaster. Though data sources do not provide data for tree mortality specific to CSU - East Bay, the broad geographic extent of the impact makes it likely that tree mortality occurred to some degree on the CSU campus system. Due to the lasting and ongoing effects of drought on the landscape, trees will continue to be impacted within the municipalities, counties and regions wherein lies the CSU campus system as long as drought conditions continue to occur in the future.

Given the absence of data, in order for the CSU Committee to assess the impact of tree mortality, it is useful to view it as a risk sub-set to the probability, location, extent, severity and duration of the drought hazard within each campus-located municipality, county and region. Regarding potential impacts, standing dead trees could fall, posing a risk to people, buildings, power lines, roads and other infrastructure. In addition, drought-impacted trees become susceptible to diseases and insect infestations (bark beetle) further adding to the risk of tree mortality and related potential impacts. No data is currently available for tree mortality on campus, however, the CSU Planning Team will pursue data on this issue in the future.

As a potential tertiary impact, prolonged and repeated drought conditions over time can produce land subsidence and the risk of damage to building foundations and infrastructure on campus resulting from ground instability and collapse. Land subsidence is defined as the vertical sinking of the land over manmade or natural underground voids. Subsidence is often the direct result of groundwater over-extraction in response to drought conditions, as well as oil and gas extraction. Weight can accelerate the process of subsidence resulting from surface development and infrastructure such as roads and buildings, vibrations from construction blasting and heavy truck or train traffic. For

example, the State Water Project’s 444-mile-long California Aqueduct has required repairs such as the raising of canal linings, bridges, and water control structures on the Aqueduct – in the Central Valley a five-mile reach of the Eastside Bypass was impacted by subsidence, and the Department of Water Resources estimated that it may cost in the range of $250 million to acquire flowage easements and levee improvements to restore the design capacity of the subsided area.47

At present, drought related damage to campus buildings and infrastructure at CSU - East Bay has not been reported, but the potential for such impacts is possible. With regard to overall potential impact, water supply/availability for CSU - East Bay is ultimately tied to broader inter-dependent, and more intensive modes of water use at local and regional scales such as agriculture and ranching, wildfire protection, larger metropolitan/municipal usage, manufacturing and commerce, tourism, recreation, and wildlife preservation. During drought periods, the State of California’s regulated water allocations are modified and often reduced, which can result in reduced water availability for all usage contexts, including CSU - East Bay. A reduction of electric power generation and water quality deterioration are also potential impact factors.

**Probability of Future Occurrence of the Hazard**

**Highly Likely** — The US Drought Monitor’s time series data (2000-2020) indicates that some degree of drought has nearly a 100% probability of occurrence in the state in any given year. Given that CSU - East Bay lies within a drought impacted region, it is prudent to extend this likelihood of occurrence to the planning area.

**Vulnerability to the Hazard**

In California, rising temperatures are projected to increase the average lowest elevation at which snow falls, reducing water storage in the snowpack, particularly at those lower mountain elevations which are now on the margins of reliable snowpack accumulation. Higher spring temperatures will also result in earlier melting of the snowpack. The shift in snow melt to earlier in the season is critical for California’s water supply because flood control rules require that water be allowed to flow downstream and that water cannot be stored in reservoirs for use in the dry season. As such, state-level drought risk factors that have led to drought’s state-wide severity and extent, and potential impacts also create drought vulnerabilities at the level of the CSU - East Bay campus.

Moreover, climate change will likely adversely impact the vulnerability of watersheds and ecosystems in their ability to deliver important ecosystem services. These changes may limit the natural capacity of healthy forests to capture water and regulate stream flows. Sierra Nevada mountain winters and springs are warming, and on average, precipitation as snowfall relative to rain is decreasing. A warming climate with reduced snowpack will result in earlier snowmelt and will subsequently reduce downstream water availability during summer and early fall.

As such, the state and the CSU - East Bay planning area stakeholders potentially have less capacity to address future drought risks due to projected temperature increases and shortages in water; ground-water withdrawals have been occurring at a deficit rate of 1 – 2 million acre feet per year, where the impacts of drought include decreased availability of water for agriculture and environmental uses.\(^49\) In forested and other vegetated areas, prolonged drought decreases the moisture content of forest fuels and increases the risk of high severity wildfires.

It should be pointed out that California is the single most productive agricultural state and its agricultural industry relies heavily on reservoir water supplied by snowmelt and rainfall runoff. Yearly variations in snowpack depths have implications for water availability as snowmelt from the winter snowpack feeds a network of reservoirs. Spring snowpack at Donner Summit reached record low levels in 2014, exceeded in 2015 by a remarkable April 1 snow-water-equivalent value of only 5% of average. Decreased precipitation since 2011 has contributed to near-record low levels in the Shasta Reservoir.50

Vulnerability of Populations

The historical and potential impacts of drought on California’s population include agricultural sector job loss, secondary economic losses to local businesses and public recreational resources, increased cost to local and state government for large-scale water acquisition and delivery, and water rationing and water wells running dry for individuals and families. As drought is often accompanied by prolonged periods of extreme heat, negative health impacts such as dehydration can also occur, where children and elderly are most susceptible. Air quality often declines in times of drought which can affect those with respiratory ailments. These same vulnerabilities apply to the students, faculty and staff of the CSU – East Bay campus.

Property Vulnerability

The historical and potential impacts of drought on property include crop loss, injury and death of livestock and pets, and damage to infrastructure, homes and other buildings resulting from the secondary drought impact of land subsidence. The related drought impacts of tree mortality and land subsidence pose risks to vulnerable critical infrastructure and property. These same vulnerabilities apply to the properties of the CSU - East Bay campus.

Natural Environment Vulnerability

The historical and potential vulnerabilities of drought in the natural environment are widespread throughout public and private lands within the state, including tree mortality, impacts to all flora and fauna, and destabilization (subsidence) of land along streams and rivers, and within watersheds.

The core issue shaping drought vulnerabilities throughout California (including the East Bay campus) s water supply and demand. Several factors play into the issue including groundwater basins, surface water run-off, public and agricultural demand, and surface water storage water sheds. A USGS led analysis was first conducted in 2010 through the Forest and Rangeland Assessment and ongoing through the USGS Forest and Rangeland Ecosystem Science Center to identify threats and assets where water supply would

benefit from environmental management designed to protect or enhance water resources, the key effort which, in part, both defines and mitigates the severity of drought risk and vulnerabilities.

With regard to overall threat and asset findings shaping the potential severity of drought, the watersheds in the Sierra region contribute most greatly to the state’s water supply, but are under threat from climate change, wildfire and development. In addition, groundwater basins in the San Joaquin Valley and Sacramento Valley bioregions are an abundant resource that is heavily threatened by over pumping.

**Critical Facilities Vulnerabilities**

Drought vulnerabilities for CSU - East Bay’s critical facilities include water shortfalls for facility operations and critical functions, and potential structural destabilization and damage resulting from land subsidence.

**Estimate of Potential Losses**

An estimate of potential losses from drought has not been calculated for the campus or the CSU system as a whole. However, drought related losses to the City of Hayward and Alameda County, and the surrounding region such as crop loss and cost increases for water resources have re-occurred over time. Please consult city and county level government, and/or state agricultural agencies for data on the financial impacts from drought.

**Vulnerability Assessment Conclusions**

The CSU Planning Committee understands that the high degree of vulnerability posed by drought will be exacerbated by greater climate variation in the future and therefore greater variation and uncertainty regarding the availability of water supplies which are already under tremendous stress. In response to such vulnerability, state legislation passed in 2014 requires local governments to regulate pumping and recharge to better manage groundwater supplies, and groundwater-dependent regions are required to halt overdraft and bring basins into sustainable levels of pumping and recharge by the early 2040s. That said, the Committee will continue to work with local, regional and state partners and stakeholders to explore solutions for mitigating the drought hazard on its campuses by accessing the best available data and resources on climate change and its relationship to drought.

**Identified Data Limitations**

Data is limited concerning campus-related agricultural assets as well as data on campus tree mortality.

**Earthquake**

**Description of the Hazard**

An earthquake is a sudden motion or shaking caused by the release of pressure accumulated along the edge of tectonic plates covering the earth. These huge plates are
constantly moving and move ever so slowly under, over, or by passing one another. This movement is gradual however the plates may lock together accumulating enormous amounts of energy. When this energy builds, stress develops, and the adjoining plates will eventually break free and result in ground shaking – an earthquake.

Large earthquakes may result in fissuring, ground settlement, and/or vertical or horizontal displacement. Earthquakes occur without warning and can result in extensive damages and human casualties. Damages associated to earthquake generated ground shaking is normally confined to a narrow area along fault trend from the earthquake epicenter. However, seismic waves may generate ground shaking resulting in damages in areas outside of the fault trend.

**Fault Rupture** – The rupture of faults is the differential movement of the two sides of the earth’s plates at the point of the fault. Horizontal or vertical displacement may be significant and occur over great distances. The movement and energy that occurs along a fault is released in waves resulting in ground shaking. The intensity of ground shaking varies based on the magnitude of the earthquake, the proximity to the earthquake epicenter, the composition of the ground sediment or rock the waves travel through, and the depth of the earthquake.

**Liquefaction** – In addition to the primary fault rupture that occurs right along a fault during an earthquake, the ground many miles away can also fail during intense shaking. As seismic waves travel through saturated granular soil; the soil begins to liquefy and act as a fluid. Soil strength and stability is lost causing the effects of ground shaking to intensify and for ground deformation to occur. These water saturated soils when shaken quickly lose the ability to support buildings, bridges, utilities, and other structures. Areas susceptible to liquefaction include places where sandy sediments have been deposited by rivers along their course or by wave action along beaches. The greater the magnitude of an earthquake and longer duration of strong ground shaking will result in an enhanced potential for liquefaction to occur. Settlement can cause damage when the amount settlement varies significantly across the length of a structure. Lateral spreading occurs when liquefaction occurs on gently sloping ground and the liquefied material at depth allows the area to slide, often toward a vertical discontinuity or “free face” such as a creek or stream channel. Liquefaction can occur in susceptible soils below bodies of water, and settlement and lateral spreading can damage structures built on or adjacent to these areas. Transportation bridges across water bodies, wharves, piers and other structures at ports and harbors, and underwater utility lines can be severely damaged by this hidden hazard.

**Subsidence** - Changes in the local environment that cause subsidence or sinkholes are called triggering mechanisms. Water is the primary factor that affects the local environment and causes subsidence. Water level decline, changes in groundwater flow, increased loading, and deterioration (such as abandoned mines) are all triggering mechanisms. Water level decline may occur naturally, or it may be the result of human action. Factors that lead to water decline are pumping (from wells), localized drainage (for construction activities), dewatering, or drought. Changes in groundwater flow can result
from an increase in the velocity of groundwater movement, and increase in the frequency of water table fluctuations, and changes in discharge (either increase or decrease). Increased loading can cause pressure in the soil, leading to the failure of underground cavities and space, such as caves. Vibrations from earthquakes, heavy machinery, and blasting may result in structural collapse, followed by surface resettlement.

**Location of the Hazard**

The State of California is particularly vulnerable to earthquake activity due to California’s location residing between two large tectonic plates. CSU East Bay is located in the East Bay area of the San Francisco Bay region at the base of the Hayward Hills. In general, fault systems surround and traverse throughout the Bay Area and Alameda County including the area of CSU East Bay. Throughout the populated areas of Hayward and surrounding cities, the ground is saturated with sediment eroded from the hills by means of multiple stream channels. Liquefaction zones rated at moderate susceptibility exist in the majority of Hayward west of Huntwood Ave.

The Pacific Plate and the North American Plate come together at the San Andreas Fault 19 miles west of the CSU East Bay campus. In addition to the San Andreas Fault, Alameda County is home to or near additional fault systems with the potential to generate strong ground shaking. The campus is additionally in close proximity to two powerful fault systems. The Hayward Fault traverses south to north along the western base of the Hayward and Oakland Hills less than ½ mile west of the CSU East Bay campus. The Calaveras Fault extends south to north 120 miles in length from San Benito County to Contra Costa County 7 miles east of the CSU East Bay campus. The 17-mile-long Mission Fault connects the Calaveras Fault with the Hayward Fault 2 miles south of the campus. The entire San Francisco Bay Area is saturated with numerous additional faults mostly paralleling the San Andreas Fault to the northwest. These fault systems are located on each side of the campus.
Figure 8-6A: Fault Lines Through CSU East Bay

Figure 8-7B: Liquification Zone CSU East Bay
Extent of the Hazard

The extent or severity of earthquake damage is expressed in terms of magnitude, intensity and duration. The amount of energy released during an earthquake is normally conveyed as a magnitude measured from a seismogram. Magnitude is expressed in numbers and decimals representing the physical size of the earthquake. The strength and effect of the shaking on the surface of the earth is classified as the intensity. Intensity is further defined from the effects the earthquake has on people, structures, and the natural environment. The intensity of an earthquake in terms of measuring magnitude and evaluating its effects is generally expressed using the Modified Mercalli (MM) Intensity Scale. Duration is the length of time the earthquake’s energy is released.

The Richter magnitude scale (Table 8-19 below) was developed in 1935 by Charles F. Richter of the California Institute of Technology as a mathematical device to compare the size of earthquakes. The Richter Scale is the best-known scale for measuring the magnitude of earthquakes. The magnitude value is proportional to the logarithm of the amplitude of the strongest wave during an earthquake. A recording of 7, for example, indicates a disturbance with ground motion 10 times as large as a recording of 6. The energy released by an earthquake increases by a factor of 31 for every unit increase in the Richter scale.

The Modified Mercalli Intensity Scale provides descriptive values of earthquake intensity that may provide greater meaning to the broader population as the description of intensity refers to the effects actually experienced. This scale uses an arbitrary ranking based on observed earthquake effects. The scale is composed of increasing levels of intensity ranging from shaking that is not recognizable to intense shaking resulting in catastrophic damages and casualties. The Modified Mercalli Intensity Scale is demonstrated below:

The graph below illustrates the increasing intensity of energy that is released and as the measured magnitude increases. While each whole number increases in magnitude represents a tenfold increase in the measured amplitude, it represents an increasing rate of 32 times more energy released in the same increase in magnitude. As the magnitude of an earthquake is measured higher, the intensity of the earthquake worsens progressively from one category to the next.
Based on the earthquake shaking potential in the Alameda County area, the campus residing along numerous fault-lines, and the fairly extensive history of earthquakes in the county and surrounding area, (including the catastrophic Loma Prieta event in 1989) the extent of the earthquake risk is considered **Moderate**.

**History of the Hazard**

The State of California has a long history of chronic and destructive earthquakes throughout the state. On average, earthquakes strong enough to result in structural damages occur three to four times a year in California, while earthquakes Magnitude 6.0 to 6.9 occur once every two to three years. Likewise, Alameda County also has a long history of earthquake activity. The entire area of Alameda County is at risk to seismic activity and has a history of significant earthquakes resulting in damages.

The April 18, 1906 San Francisco Earthquake became one of the most well-known earthquakes in California history. The earthquake caused extensive damage to buildings, bridges, water systems, and critical facilities. Damage was experienced well beyond San Francisco including areas such as Monterey and Santa Cruz. 3,000 people were killed and thousands more injured. The San Francisco Earthquake was found to shift the course of northern California rivers. The shaking was felt from Oregon to Los Angeles.

The October 17, 1989 Loma Prieta Earthquake shook a large part of northern California, especially the San Francisco Bay Area. The earthquake caused $5.9 billion in damages, most extensively in San Francisco, the East Bay, and South Bay areas. The earthquake resulted in extensive infrastructure damages, 12,000 displaced, 3,757 injuries, and 63 fatalities. The earthquake was provided a federal disaster declaration (DR-845).

**Potential Impacts of the Hazard**

The shaking of the ground from earthquakes can result in building collapse, bridge failure, utility disruptions and other structural collapse. Large earthquakes can additionally cause natural gas lines to break resulting in structure fires. The proximity to the unstable soils surrounding the campus presents a potential for liquefaction creating greater ground instability during seismic events. A major earthquake in the San Francisco Bay Area would likely result in region-wide social disruptions in addition to structural damages. The region-wide structural damages may disrupt lifelines and supply chain routes limiting the campus from effective evacuation routes and receiving necessary supplies or equipment.

Most injuries resulting from earthquakes are from collapsing walls, flying glass, or other objects moved by ground shaking. The lack of warning allows individuals minimal time to react and find areas of safety. A moderate earthquake occurring near Hayward could cause injuries or fatalities to members of the campus community or support networks the campus relies on. These earthquake effects might be aggravated by collateral incidents such as fire, flooding, hazardous material spills, dam/levee compromises, and other cascading events. A catastrophic earthquake near Hayward could result in extensive casualties, expansive structural damages, panic, widespread utility outages,
communication failures, and secondary emergencies such as fire. A catastrophic earthquake would certainly affect the broader Alameda County and East Bay region limiting immediate assistance that the campus may normally expect.

Local impacts to CSU East Bay campus caused by an earthquake could include:
- Damage and secondary fires to industrial facilities on west side of Hayward
- Potential hazardous material releases on and off campus
- Infrastructure damage to freeway system
- Structural damage to bridges over waterways and flood control channels
- Potential isolation of campus from community
- Potential isolation among on-campus residents
- Structural damage to Alameda Creek levees and levees along San Francisco Bay
- Potential landslide and roadway damage to Carlos Bee Blvd and Harder Rd limiting access to campus
- Potential liquefaction-based effects to isolated sections of the campus and large areas of the surrounding cities
- Structural damage to campus academic and support buildings
- Structural damage to residence halls resulting in displaced student populations
- Structural damage to nearby residences
- Community members arriving on campus for refuge from damaged homes
- Damaged university communications, computer systems, and networks
- Considerable stress and fear among community
- Closure or reduction of service to campus operations
- Reduction of campus revenue

Probability of Future Occurrence of the Hazard

The Working Group on California Earthquake Probabilities (WGCEP), a collaboration between the United States Geological Survey (USGS), the Southern California Earthquake Center (SCEC), and the California Geological Survey (CGS) develops Uniform California Earthquake Forecasts (UCERFs) using the best currently available science and technology. The UCERF version 3 provides a three-dimensional view of the likelihood a region in California will experience a Magnitude 6.7 or greater earthquake in the next 30 years. The likelihood for the Alameda County fault systems surrounding the East Bay region is included in the following table.
Table 8-22: Major Potentially Active Faults in Proximity to CSU East Bay

<table>
<thead>

<td>7.8</td>
<td>7%</td>
</tr>
</tbody>
</table>

There is a 76% probability of one or more magnitude 7.0 earthquakes striking Northern California within 30 years beginning in 2014. Based on the earthquake shaking potential in the Hayward area, the proximity to the Calaveras, Hayward, and San Andreas Fault Systems, the probability of seismic ground shaking that would generate damage is considered Possible.

Vulnerability to the Hazard

A considerable challenge regarding earthquakes is they generally occur without warning. The fault systems surrounding the region all cross major transportation routes potentially reducing the availability of access and the supply chain. The geographic location of CSU East Bay places the campus in an urban/suburban community near residential, commercial, and industrial areas that is moderately populated. Earthquake effects experienced in the neighboring local community will likely spill over onto the campus.

The known fault systems generating the threat to the San Francisco Bay region generally surround the area and some cross near the CSU East Bay campus. The campus resides in a region that is exposed to fault systems on all sides. The proximity and potential for large earthquake development from these surrounding systems expose significant vulnerabilities. The potential for earthquake damaged structures being left uninhabitable including campus residence halls will result in numerous displaced individuals and households. The lack of earthquake insurance will cause extreme financial burdens on those affected.

Elements of the vulnerability to a major earthquake on the CSU East Bay campus will vary depending on when the earthquake were to strike. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks.

Conversely, during the days and hours that classes are in session and staff are at their workplaces, the human vulnerability increases. Generally, people are safer when at home in wood frame structures as earthquakes tend to generate less structural damage to wood construction than in commercial or industrial facilities. The greater number of people on campus at the time of an earthquake will result in more people being exposed to effects from damaged campus facilities or equipment and require greater evacuation assistance. However, in region-wide events this vulnerability may simply shift to the homes and workplaces of members of the campus community and their families.

The aftermath of a major earthquake will likely result in widespread search and rescue operations for trapped and injured individuals. The demand on emergency services will be great, potentially requiring the campus community to be prepared for these scenarios and initiate response actions as needed. There will be needs for emergency medical care, shelter, water, and food for individuals who have been displaced by the earthquake. In earthquakes causing significant damages, there may be a necessity to provide assistance with identification and support to local agencies in mass fatality management.

There may be a need to evacuate members of the campus community from the campus and to other locations that are deemed to be safer locations. This may be heightened in the southwestern portions of the campus as this area has been identified as being within a liquefaction zone. As access routes to and from the CSU East Bay campus is exposed by dam facilities, the decision to evacuate will need to take into account whether flood control facilities are filled with water and the actual threat to the dam or levees.

The San Francisco Bay Area and both Hayward and Concord in particular are moderately populated and attract commuter employees to the commercial cores. The road and freeway network becomes easily congested in normal situations. A major earthquake has the potential for rendering these critical lifelines and supply routes inoperable and forcing the campus community to be self-reliant for a period of time.

Certain campus populations will experience greater challenges to a post-earthquake environment. Vulnerable populations including those that rely on specific services, require electrical power, homeless students, experience disabilities, non-English speakers, those whose age make evacuating difficult, and others will be most affected. These individuals will likely need to navigate through earthquake generated debris, extreme stresses of a disaster, an inability to communicate to or gain access to support networks, and find difficulty in accessing equipment or supplies to aid in a specific need.

**Estimate of Potential Losses**

Estimates of potential losses will be influenced by a variety of factors. The intensity of the earthquake will determine what scale of damages affecting campus infrastructure, equipment, and other impacted features. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to earthquake are $164,768,550.

Vulnerability Assessment Conclusions

It is difficult to predict the severity of casualties, property, and cascading impacts generated by future seismic events affecting the greater San Francisco Bay region, the East Bay, and the CSU East Bay campus. Each of the earthquake generated effects will vary widely based on the intensity of the earthquake, location of the epicenter, proximity to people and development, time of day and year, the soil composition under the impacted structures, building construction, among others. In any case, the potential for a major earthquake exists affecting the campus and causing extensive challenges to the CSU East Bay campus and community.

In the event that a major earthquake was to strike along the many fault systems surrounding Hayward, the effects could be significant to the campus community and campus operations. The widespread impacts generated by a major earthquake would extend the effects of casualties, damages, and other impacts to the broader San Francisco Bay region creating large-scale regionwide needs for critical assistance and a heavy demand on limited emergency resources. The threat and impacts presented to the campus will be shared with the campus community from their homes and places of work. The campus will likely be required to address critical needs independently during early phases of the disaster.

The campus population are additionally vulnerable to the effects of major ground shaking that are far reaching. The psychological and social impacts a major earthquake will give
rise to will potentially harm individuals and cause tremendous fear. The willingness to return indoors may be hampered especially as after-shock continue. These effects are magnified for populations having specific vulnerabilities or access limitations.

Identified Data Limitations

Missing campus structural replacement costs and an inventory of building construction types to include status of earthquake retrofitting. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.
Erosion

Description of the Hazard

The US Geological Survey (USGS) defines erosion as “the process whereby materials of the earth’s crust are loosened, dissolved, or worn away and simultaneously moved from one place to another.”\textsuperscript{57} Erosion may occur in areas of streams and rivers, along bluffs, around immovable objects (such as buildings or bridge abutments), or as a cascading result of other natural hazards, such as earthquakes or wildfires. When erosion occurs along bodies of water, the removal of material causes the shore to move further landward.

Forces such as sea level rise and changes in sediment supply impact erosion gradually and can be difficult to recognize. In contrast, the impacts of short-term events, such as storms and flooding, can be severe and are immediately recognizable. Along the Pacific coast, rain, wind, and waves can induce significant short-term erosion.

Location of the Hazard

Erosion is a severe hazard in coastal communities, where sea level rise and storms contribute to de-sedimentation and the retreat of coastal cliffs, bluffs, and beaches. While coastal erosion can happen in any storm, it is more likely during El Niño events, which occur every 5-7 years. As such, for the purpose of this campus-level analysis, the erosion hazard poses a consistent risk across the terrain of the CSU-East Bay campus with erosion-prone characteristics. While it is understood that such conditions exist generally, no specific locations under threat of erosion or erosion-in-process have been identified. Such an assessment may be conducted by campus leadership at some point in the future.

Other incidents of erosion, such as occurs around buildings, are relatively non-spatial and can occur in any locations with conducive soil structure and a source of movement, such as water or wind. An area’s potential for erosion is determined by several factors, including rainfall, topography, soil characteristics, and vegetative cover.

Extent of the Hazard

There is no published scale of severity or extent for this geologic hazard. If conditions are favorable, erosion is likely to occur. Given no historical occurrence of erosion on campus, the planning committee ranks the extent of this hazard as Low.

History of the Hazard

While there have been incidents of riverine erosion in other parts of Hayward County, no incidents have been recorded on the CSU East Bay campus.

Potential Impacts of the Hazard

Coastal erosion can result in severe impacts to infrastructure, including the undermining of foundations, exposure of underground infrastructure, and breaches of natural or constructed protections. The latter can expose communities to the destructive forces of floodwaters, surge, and debris impacts. On campus, areas of erosion can create pedestrian and transportation hazards, and structures may become unsafe if erosion is not controlled. Public health and safety, structures, and infrastructure can all be negatively impacted, damaged, or destroyed by the erosion hazard.

**Probability of Future Occurrence of the Hazard**

Erosion is an on-going and dynamic process that occurs regularly. As climate change induces more frequent and intense weather events, coastal and other erosion may generally become more widespread or severe. These events can cause erosion or exacerbate areas already experiencing erosion. As a result, and in consideration of the potential extent of erosion, the probability of future occurrence is high over the long term.

**Vulnerability to the Hazard**

Topography, soil structure, land use, and precipitation are all factors of erosion. CSU East Bay infrastructure and buildings located on steep slopes, in areas with little vegetation, or in areas with conducive soil types are more vulnerable to erosion.

In the wider Hayward community, erosion vulnerabilities include agricultural sector job loss, degradation of riverine ecosystems and coastlines, and loss of water quality.

**Estimate of Potential Losses**

The historic and potential impacts of erosion on property statewide include reduced agricultural productivity, lower surface water quality, and damaged drainage networks. Current modeling is not precise enough to allow for an assessment of potential losses to buildings and infrastructure on campus.

**Vulnerability Assessment Conclusions**

While the ability to predict future erosion on the CSU East Bay campus is limited, the core issues shaping erosion vulnerability on campus are flora and landscaping. If left unchecked, erosion can cause significant damage to campus infrastructure and the surrounding environment.

**Identified Data Limitations**

The complex interactions between soil erosion factors make predictive modeling, determination of hazard areas, and quantification of loss difficult. Localized data on this hazard is also limited, resulting in more generalized findings.
Description of the Hazard

The incredible geographic diversity in California presents tremendous challenges for flood planning and response. The state is home to extensive mountain ranges such as the Sierra Nevada, Cascades, Klamath, Coastal Ranges, and the Southern California Transverse Range all creating tremendous watersheds. Large river systems drain the mountains traveling through populated communities including the Sacramento and San Joaquin Rivers draining into the California Delta. The state has a complex system of reservoirs, dams, and levees providing water storage and flood protection. Finally, California’s 840-mile coastline exposes the coastal regions to tidal influences.

Floods are characterized by the rising and overflowing of excess water from a water source such as a stream, river, lake, canal, or coastal body onto an area of normally dry floodplain. A floodplain is a lowland area downstream and adjacent to water bodies that are subject to flood events. Flooding is a naturally occurring event that become hazardous when populations and property are affected.

Flooding can result from excessive precipitation from weather systems generating prolonged rainfall, excessive snowmelt from watersheds upstream from the floodplain, infrastructure failure, exceeding the capacity of dams or levees, tidal influences, or a combination from any of the previous factors.

Floods represent one of the costliest and most frequent natural disasters that influence human suffering and economic impact in the United States. Flooding will likely result in significant damage to structures, infrastructure, utilities, landscapes, and the environment. Erosion of stream banks, roadways, other features may result from the movement of flood waters. The saturated ground resulting from standing flood waters may cause ground instability, collapse, erosion, or other damages. Further, floods will often generate substantial debris that will accumulate and be deposited throughout the flooded areas.

Flooding can be either slow-rise or rapid onset floods. With slow rise floods, there is often warning preceding water rise by hours or days before dangerous conditions present themselves. Slow rise floods that are expected to enter into populated areas generally allow for some time to initiate evacuation and sand bagging efforts. Flooding that occurs rapidly conversely are water events that present with extremely limited warning times and a limited ability to take response actions until flooding has already begun to occur.

Flooding may take on different forms:

**Flash Flooding** – Flash flooding is typically characterized by a rapid rise, short duration, and large volume of water in a localized area. Heavy rainfall in areas that have limited drainage capacities often contribute to flash flooding conditions. These flooding events frequently occur with limited notice requiring immediate evacuation or rapid response efforts such as sand bagging. Flash flooding may arrive with fast moving water creating added hazardous conditions.
Riverine Flooding – Riverine flooding is usually caused by prolonged rainfall or rainfall combined with heavy snowmelt. When soils are already saturated, the ability for the ground to absorb water is minimized. In a riverine flood, the water way exceeds channel capacity and extends into areas outside of the channel, often in developed communities. In California, riverine flooding is most likely to occur from November through April. The duration of riverine floods may vary from a period of hours to weeks.

Localized Flooding – Localized flooding is commonly the result of stormwater drainage systems being overwhelmed by unusually heavy rainfall. These flooding events frequently occur in areas that are urbanized or developed with greater amounts of impervious surfaces not allowing ground absorption. This generates added runoff into the drainage systems and onto roadways creating backups.

Infrastructure Failure – Failures of dams or levees presents a serious flooding concern for areas downstream from the compromised structure. This situation may result in a catastrophic flood with limited warning time and widespread areas affected.

Coastal Flooding – Coastal flooding can occur in multiple areas along the California coastline. Flooding may result from intense storms coming from the Pacific Ocean that generate elevated water levels or storm surge. The size, duration, winds generated, and intensity of the storm will influence the effect the waves will have on the shoreline. Periods of high tide can aggravate the conditions allowing greater wave impingement into coastal areas.

Atmospheric River

California, including the location of this campus, is subject to the effects of a phenomenon referred to as atmospheric rivers. These weather events consist of long, narrow regions in the atmosphere transporting tremendous amounts of water vapor from the tropics. These weather regions behave like rivers in the sky. They can carry heavy volumes of water vapor compared to the amount of water flow at the mouth of the Mississippi River. As these atmospheric rivers arrive into California they tend to generate significant rain and snow.

Atmospheric rivers can arrive in many different shapes and sizes. The larger events are able to generate extreme rainfall amounts resulting in flooding. They can stall over watersheds vulnerable to flooding, often saturated with heavy snow amounts. The atmospheric rivers known as a “Pineapple Express” coming from the tropics and arriving with warmer air may produce heavy rains that will melt ground snow adding to the water volume that will be added in the flood runoff.

These events can produce heavy amounts of precipitation creating extensive damages. However, these events may present as weaker systems that produce precipitation that is enough to be beneficial for the local water supply. At the higher elevations in the California mountains, these events have the potential to generate a tremendous snowpack providing a source of water during the dry summer months.
Location of the Hazard

Hayward is located in Alameda County on the east side of the southern San Francisco Bay. Alameda County can experience flooding from overflowing streams and heavy precipitation events in low lying areas such as Castro Valley, San Leandro, and Hayward. These areas often experience shallow flooding impacting roadways and other areas where drainage is inadequate. The western side of Alameda County is a coastal plain adjacent to the San Francisco Bay that gradually rises to the east at the Hayward Hills. The communities in western Alameda County are densely populated with extensive residential neighborhoods. Within 2 miles of the campus are large industrial zones containing a variety of land uses including chemical facilities and distribution centers shipping different materials.

The CSU East Bay campus is located elevated on the hills limiting the flooding potential that exists in the low-lying areas. The campus is situated on a topography of rolling hills 300-400 feet higher than the coastal basin located 0.5 miles away. Creek beds that have been carved into valleys among the hills surround the campus with Ward Creek ¼ mile to the north and Ziele Creek 0.25 miles to the south. The entire CSU East Bay campus sits within a Special Flood Hazard Area (SFHA) Zone X: Area of Minimal Flood Risk designation on the Flood Insurance Rate Map. The CSU East Bay, Concord Campus, located 20 miles to the north in Contra Costa County also resides in a Zone X: Area of Minimal Flood Risk.

**Extent of the Hazard**

The CSU East Bay campus is located entirely in a designated Zone X: Area of Minimal Flood Hazard. The access routes into and out of the campus servicing locations to the north and west are found in areas primarily designated as Zone X: Area of Minimal Flood Hazard, access routes to and from the south and east are primarily located in Zone X:
Area with Reduced Flood Risk Due to Levee. The CSU East Bay, Concord campus is also located entirely in a designated Zone X: Area of Minimal Flood Hazard as are the access routes into and out of the facility. Based on these factors, the planning committee ranks the extent of the hazard as **Low**.

In support of the NFIP, FEMA identifies those areas that are more vulnerable to flooding by producing Flood Hazard Boundary Maps (FHBM), Flood Insurance Rate Maps (FIRM), and Flood Boundary and Floodway Maps (FBFM). Several areas of flood hazards are commonly identified on these maps, including the 1% annual chance flood zone. Flood zones are further delineated by risk and are assigned a letter signifier. The flood zone designations are defined and described in the following table.

**Table 8-24: Flood Zone Designations and Descriptions**

<table>
<thead>
<tr>
<th>Zone Designation</th>
<th>Percent Annual Chance of Flood</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. Because hydraulic analyses have not been performed, no base flood elevations (BFEs) or flood depths are shown.</td>
</tr>
<tr>
<td>Zones VE and V1-30</td>
<td>1%</td>
<td>Areas along coasts subject to inundation by the 1% annual chance of flooding with additional hazards associated with storm-induced waves. BFEs derived from detailed hydraulic analyses are shown within these zones. (Zone VE is used on new and revised maps in place of Zones V1-30.)</td>
</tr>
<tr>
<td>Zone A</td>
<td>1%</td>

<tr>
<td>Zone AH</td>
<td>1%</td>
<td>Areas with a 1% annual chance of flooding where shallow flooding (usually areas of ponding) can occur with average depths between 1 – 3 feet.</td>
</tr>
</tbody>
</table>
Zone AO  1%
Areas with a 1% annual chance of flooding, where shallow flooding average depths are between 1 – 3 feet.

Zone X (shaded)  0.2%
Represents areas between the limits of the 1% annual chance of flooding and 0.2% chance of flooding.

Zone X (unshaded)  Undetermined
Areas outside of the 1% annual chance floodplain and 0.2% annual chance floodplain; areas of 1% annual chance sheet flow flooding where average depths are less than one (1) foot; areas of 1% annual chance stream flooding where the contributing drainage area is less than one (1) square mile, or areas protected from the 1% annual chance flood by levees. No BFE or depths are shown within this zone.

History of the Hazard

Flooding in Hayward and the broader Alameda and Contra Costa County region have typically occurred during the winter months when Pacific storms are more common. The occurrences of significant flooding typically have been the result of successive intense storms with heavy precipitation. The region has experienced flood events that have caused tens of millions of dollars in damages and numerous fatalities. The following provides insight into information of past flooding events that are significant to the CSU East Bay campus. No history of flooding is reported for the campus.

### Potential Impacts of the Hazard

A flood will potentially result in extensive amounts of water entering onto developed areas. The force and volume of water that is generated by a flood may cause extensive structural damage in areas subject to standing or moving water. The effects of flooding may spread over significant distances covering large areas of land. The extent of the impacts would vary based on a number of factors such as the volume of water flooding, the time of the flood event, the amount of warning provided, the location and extent of the flood boundary, facility elevation, and distance from the flood source. Potential impacts resulting from flooding include:

- Injuries or loss of life
- Property destruction or damage
- Loss of property contents
- Infrastructure damage including roadways, bridges, other transportation means
- Public health hazards resulting from mold, mildew, and disease due to flood water
- Flooded or destroyed lifelines/supply routes
- Damaged or destroyed utilities
- Loss of community economic base
- Employment losses
- Agricultural (crops and livestock) damages or destruction
- Environmental damage
- Prolonged periods of necessary dewatering
- Flooding erosion may alter natural drainage channels
- Societal and community impacts
- Psychological impacts of impacted populations
Disruptions to education delivery to community
Damage or destruction of academic materials, fine arts, and research
Damage or destruction of university computer systems and networks
Damaged university infrastructure
Inability for campus operations to resume
Reduced or eliminated student engagement with academic programs
Reductions in campus revenues

Additionally, individuals who were unable to evacuate in time or refused to leave will likely need assistance or rescue from the flooded area. Remaining in or being trapped by flood waters places individuals in significant risk of injury or death. The impacts extend beyond the danger placed upon the affected individual and places greater resource demands on agencies and organizations making efforts to rescue trapped individuals.

Probability of Future Occurrence of the Hazard

Alameda County and Contra Costa County have numerous areas that are determined to be at risk from flooding. The location of the CSU East Bay campus resides outside of any Special Flood Hazard Area and is elevated in the hills east of Hayward. The CSU East Bay, Concord campus also is outside of Special Flood Hazard Area but is bordered by the Galindo Creek, considered a Regulatory Floodway, on the east side of the campus. Areas designated as a Special Flood Hazard Area remain at a distance from either campus. Slight potential exists for urban flooding due to heavy precipitation that overwhelms drainage systems on campus.

Based on the (above) factors, the planning committee ranks the probability of future occurrence for flooding as Unlikely.

Vulnerability to the Hazard

The CSU East Bay campus is subject to the effects of limited, small-scale flooding or ponding primarily resulting from excessive precipitation during isolated heavy storms, river/levee and/or drainage system overflow, or a combination of these. The Ward Creek and Ziele Creek are located close to the campus, however, present minimal potential for flooding and damage on campus and surrounding residential areas. The creek channels that surround the campus have limited storage or volume capacities and create limited vulnerabilities in the transportation network servicing the campus.

Vulnerability to flooding on the CSU East Bay campus will vary depending on when the flood was to occur and the location of people and assets located within any low lying areas. The risk to the campus population will be lessened during periods when classes are not in session or during periods of breaks.

It is unlikely, but should an urban flood occur, impacts may pertain to campus equipment, communication systems, protected documents, artwork, academic materials, computer
systems, research, and other critical activities on lower levels of buildings located in low lying areas on campus.

Estimate of Potential Losses

Estimates of potential losses will be influenced by a variety of factors. The volume and force of the water will determine the scale of damages affecting campus infrastructure, equipment, and other impacted features. The location and elevation above flood waters will affect the level of damage and individuals exposed. The time of the academic year, the day of week, and hour in which the flooding was to occur will influence the number of people on campus and potential casualties. The severity of the storms producing precipitation, the speed of the storms moving across the area, the level of snowpack in the higher elevations, and amount of resulting snowmelt will produce varying effects on damages produced and costs incurred. Losses will be generated by the physical damages, the loss of revenue, loss of academic research, loss of building contents, and community wide economic reductions.

Based on estimate replacement costs of facilities and structures on campus, the maximum total replacement costs due to flood are $164,768,550. However, it is unlikely for flood to cause destructive losses to the entire campus.

Vulnerability Assessment Conclusions

While the campus is located in an area of minimal flood potential (Zone X), the primary vulnerabilities to flood on campus are people and assets in low lying areas exposed to mostly localized flooding and ponding from overflow of campus creeks or low probability, large-scale storms that produce heavy amounts of precipitation directly over
the campus and surrounding neighborhoods. The proximity to the Ward Creek and Ziele Creek further presents an additional flood hazard risk factor for the campus.

The potential for flooding on campus, although limited, generates potential for a number of cascading effects such as disruptions to the local economy, utility failures, disruptions to providing for the needs of the community, and development of public health hazards. These effects would be exacerbated by effects of seasonal flooding, ongoing heavy precipitation, or excessive run-off from the watershed contributing to the river system. The potential for widespread flooding and damage of structures due to the force of water has exponentially powerful impacts on particular populations among the campus community including those with access or functional needs, international students, the homeless, and students residing in the residence halls.

**Identified Data Limitations**

Missing campus structural replacement costs and complete inventory of building construction features or mitigation efforts to lessen the impact due to flood inundation. HAZUS generated analysis is focused on the broader community level versus finetuning the analysis to the micro-level for facilities such as a university campus.

**Hazardous Materials**

**Description of the Hazard**

A hazardous material is defined in California’s State Hazardous Materials Incident Contingency Plan (1991) as “a substance or combination of substances which, because of quantity, concentration, physical, chemical, or infectious characteristics may: cause, or significantly contribute to an increase in deaths or serious illnesses; and/or pose a substantial present or potential hazard to humans or the environment.” Hazardous materials are one or more of the following: flammable, corrosive or an irritant, oxidizing, explosive, toxic (poisonous or infectious), thermally unstable or reactive, or radioactive. Hazardous materials are ubiquitous in modern society and may be found at all stages of production, consumption, and disposal.

Federal and state laws permit the intentional release of some hazardous materials into the environment such that the risk to human health and the environment is thought to be acceptable. However, sometimes releases are unintentional, resulting from leaks, accidents, or natural hazards. This section focuses on such accidental releases and fall into the following key categories:

**Fixed Hazardous Materials Incident:** A fixed hazardous materials incident is the accidental release of chemical substances or mixtures during production or handling at a fixed facility.

---

Transportation Hazardous Materials Incident: A transportation hazardous materials incident is the accidental release of chemical substances or mixtures during highway, waterway or air transport. Populations, built and natural environments are potentially impacted.

Pipeline Incident: A pipeline transportation incident occurs when a break in a pipeline creates the potential for an explosion or leak of a dangerous substance (oil, gas, etc.) possibly requiring evacuation. An underground pipeline incident can be caused by environmental disruption, accidental damage, or sabotage. Incidents can range from a small, slow leak to a large rupture where an explosion is possible. Inspection and maintenance of the pipeline system along with marked gas line locations and an early warning and response procedure can lessen the risk to those near the pipelines.

Hazardous materials can also be classified according to worker safety and health. Information provided by California Division of Safety and Health includes guidelines related to:

Safety hazards (fire and fire byproducts, electricity, flammable gases, unstable structures, demolition, sharp or flying objects, excavations)

Health hazards (carbon monoxide ash, soot and dust; asbestos; hazardous liquids; other hazardous substances; heat illness)

Natural-Technological Incidents (Natechs): During the past two decades, increasing attention has been given to hazardous materials releases resulting from Natechs or a natural disaster event that triggers a technological hazard event. Natechs are of particular concern for the following reasons:

- They can produce a simultaneous effect on many industrial facilities
- Can overwhelm response capacity
- Containment systems may fail
- May produce cascading disasters
- Response may be hindered by a disaster’s impact on the physical environment

Location of the Hazard

Hazardous materials and infrastructure such as fuel tanks, rail lines, chemicals, hazardous waste sites and gas pipelines to varying degrees are located within the CSU system

and/or within its surrounding communities. The planning committee indicates that chemicals are located in the science lab, but otherwise no known hazardous materials are present on campus. At larger scales (beyond the campus planning area) hazardous materials and infrastructure are located throughout the city of Hayward and Alameda County, and reflect different types, configurations and scales dispersed across these geographic areas.

Extent of the Hazard

There is no comprehensive statewide vulnerability assessment available at this time. As such, the true extent of the hazardous materials risk in California and its communities is not known, meaning no overarching conclusions have been reached which have been able to integrate all qualitative and quantitative risk factors to produce a comprehensive measure of the extent of the hazard.

However, for the CSU – East Bay planning committee, although no hazmat events have taken place on campus, and hazardous materials are limited to chemicals in the science building, railroad and gas pipelines, chemical and hazardous waste sites are located close to the campus. Based on these factors along with the types and levels of hazardous materials in the larger community, it is prudent to rank the extent of the hazard for the CSU – East Bay campus as Moderate, and to consider worst case scenarios as the main driver of policy in order to fully mitigate all possible hazardous materials event outcomes.

For example, 400 hazardous materials problems are tied to 32 past earthquakes, including more than 495 documented hazardous materials releases due to the Loma Prieta Earthquake alone (this number excludes innumerable leaks in Pacific Gas & Electric’s natural gas distribution system). That said, it is likely that many such hazardous materials releases have received little attention in the past because public authorities, the media, and the public have overlooked them in the rush to address and recover from immediate disaster threats, and that responsible parties may have an incentive to understate the extent of releases or not to report them at all.

History of the Hazard

According to the CA Governor’s Office of Emergency Services’ Hazardous Materials Spill Report, the state experiences from 10 to 30 spill events daily. As of April 2021, a total of 2,096 spill events had occurred so far this year. Such events have occurred in all the cities and/or counties where CSU campuses are located.

No hazmat incidents have taken place on the CSU – East Bay campus.

Potential Impacts of the Hazard

---

A large hazardous materials release could affect an entire community or city under certain conditions related to direction of air flow (air-based chemical release) and population density or the contamination of a community’s main water supply. Either type of release could necessitate large scale evacuation. By contrast, in the rural unincorporated areas where population densities are low, even in the event of a large release, the number of homes that may need to be evacuated would be significantly lower than in an urban environment. The occurrence of a hazmat incident can also result in the shut-down of transportation corridors which can last for hours at a time while the impacted area is stabilized.

The release of some toxic gases may cause immediate death, disablement, or sickness if absorbed through the skin, injected, ingested, or inhaled. Contaminated water resources become unsafe and unusable, depending on the amount of contaminant. Some chemicals cause painful and damaging burns if they come in direct contact with skin. Prolonged and concentrated exposure to such chemicals can produce severe long-term impacts to respiratory, endocrine and nervous systems, heart and brain health.

The potential impacts of chemicals and toxic gases discussed here also apply to the students, staff and environment on the CSU – East Bay campus.

With regard to the natural environment overall, contamination of air, ground, or water may result in harm to fish, wildlife, livestock, and crops. The release of hazardous materials into the environment may cause debilitation, disease, or birth defects over a long period of time. Loss of livestock and crops may lead to economic hardships within the community.

Recent California examples include the 2016 Aliso Canyon methane gas leak\(^{68}\), which caused evacuation of nearby residents, many of whom experienced temporary health problems such as difficulty breathing and eye irritation; and the 2016 Fruitland metal recycle plant fire in Maywood, which released heavy metals such as lead, magnesium, copper, aluminum, antimony, calcium, iron, sulfur, tin, potassium, and zinc which pose severe risks to public health.\(^{69}\) Health effects from exposure to these metals included short-term symptoms such as irritation to the eyes, nose, throat, and lungs.

**Potential Impact of the Hazard (Natechs)**

Natural disasters, including earthquake, flood, and fire also pose risks to public health and the environment. For example, following the Northridge Earthquake, California State University (CSU) Northridge laboratories and chemical storage rooms experienced multiple chemical spills. Such incidents, triggered by a natural disaster, pose a significant risk to students, faculty, staff, and first responders. At a minimum, all CSU campuses with

---

a science lab (including CSU – East Bay) is at risk of potential impact from a natural-
technological (combined impact) event.

In a severe flood event, floodwaters are often contaminated with hazardous materials
posing a threat to public and animal health, groundwater, and other parts of the
environment. These hazardous materials may be released from damaged or flooded
underground tank sites (e.g., gas stations or chemical storage facilities), propane tanks,
manure or human waste handling facilities, fertilizer and pesticide storage, agricultural
sites, and household hazardous waste.

In a fire event, (such as the October 2017 Northern California firestorms which destroyed
approximately 6,000 residences) entire neighborhoods can be burned to the ground.
Hazardous material release creates public health concerns which can delay the initial
steps of fire recovery, including reopening burned areas to residents and initiating debris
removal activities. The post-fire “toxic sweep” poses a risk of coming into contact with
toxic substances due to the presence of synthetic and hazardous materials.

Probability of Future Occurrence of the Hazard

The probability of occurrence for a hazmat event on the CSU – East Bay campus can be
viewed in two different ways: the history of occurrence serves as a sound predictor of
future probability assuming current risk and vulnerability factors remain somewhat
constant. For the purposes of the current estimate, no current data clearly indicates
otherwise. As such, the probability of occurrence is Low because the CSU – East Bay
campus has no known hazardous materials other than chemicals in the science lab, and it
has not experienced a hazmat event. That said, hazmat occurrences are largely based on
human error, and any changes in risk and vulnerability factors such as a decreased
vigilance in materials oversight and handling practices or changes in the amount of
chemicals or exposure will likely increase the probability on campus.

Vulnerability to the Hazard

Hazardous materials pose a risk to the CSU – East Bay campus. As identified by the
campus planning committee and on the hazmat map, the following vulnerabilities are
present on campus: chemicals are present in the science lab, and a rail line, gas pipelines,
chemical and hazardous waste sites are very close to the campus footprint. Gases and
chemicals or hazardous waste, if spilled or released, could severely impact human health
and campus operations.

Although it is quite difficult to produce a quantitative measure of vulnerability because
( unlike natural hazards) the probability of occurrence is dependent on human error, which
itself is variable based upon a fluctuating set of interrelated factors, some of which lack
prediction or control, given the complexity of how all natural and built environments and
hazmat risks factors interrelate at the local or campus level, it is prudent to assume for
planning purposes that the campus’ vulnerability is a sub-set of the larger community’s
vulnerability. As such, the CSU – East Bay leadership maintains vigilance to mitigate the
campus’ vulnerabilities identified above at a minimum.
Estimate of Potential Losses

As discussed previously, it is difficult if not impossible to produce an accurate quantitative measure of vulnerability because of the variable nature of a hazardous materials spill. For example, the release of a toxic airborne chemical in a populated area has severe impact potential, whereas the impact potential of a small chemical spill in a remote or rural area is most likely limited to remediation of soil. And, in both cases, the probability of occurrence is dependent on human error, which itself is variable based upon a fluctuating set of interrelated factors, some of which lack prediction or control. In all cases, different types and amounts of hazardous materials interact with fluctuating combinations of human error to produce different event outcomes with variable impact costs.

Vulnerability Assessment Conclusions

It is well understood that with regards to hazmat vulnerability, each campus and its surrounding community (including CSU – East Bay) operates through a complex and dynamic interaction between industrial and commercial inputs and outputs and the natural and built environment. Such activity produces hazardous materials that move through the environment along both convergent and divergent routes and across all levels of land-use from site to campus to city and county and beyond. It is also clear from a review of the Alameda County hazard mitigation plan and Cal OES’ records of hazardous material spills, that such events occur with great frequency and varying degrees of severity across jurisdictions statewide. As such, in assessing the vulnerability of the CSU – East Bay campus, campus-level risks and vulnerabilities are not discreet or isolated but can become exacerbated or augmented through connections to broader community-level hazmat risks and vulnerabilities.

Finally, in order to draw conclusions on vulnerability, it should be noted that any identified vulnerabilities at the campus level and/or community level are circumscribed and potentially reduced by targeted policy and program interventions. Numerous policies and programs have been established in recent years in response to California’s widespread and complex and integrated hazardous materials risks - California established the Unified Program which consolidates and integrates the administrative requirements, permits, inspections, and enforcement activities of the following environmental and emergency response programs: the Aboveground Petroleum Storage Act (APSA) Program, Area Plans for Hazardous Materials Emergencies, the California Accidental Release Prevention (CalARP) Program, the Hazardous Materials Release Response Plans and Inventories (Business Plans), Hazardous Material Management Plan (HMMP) and Hazardous Material Inventory Statement (HMIS) requirements (California Fire Code), the Hazardous Waste Generator and Onsite Hazardous Waste Treatment (tiered permitting) Programs, and the Underground Storage Tank Program.

Identified Data Limitations
The CSU – East Bay planning committee has provided information on campus-level hazmat materials and risks. Data limitations pertain to a comprehensive understanding of human activity and error related to materials control over the long term.
**Landslide**

Description of the Hazard

A landslide is a down-slope movement of soil, rock, or other debris, and can also be referred to as a mass movement or slope failure. These geological hazards can range in size from a few feet to over a mile in length and width and, when heavy and rapidly moving, can cause serious damage and loss of life.

Landslides are classified based on the type of material and type of movement involved. They can range from slow-moving earth flows to fast-moving debris flows, though many large slope failures involve more than one type of movement. The primary natural triggers of slope failures are water, seismic activity, and volcanic activity. Slope saturation by water can occur from intense rainfall, snowmelt, changes in ground-water levels, and surface-water level changes along coastlines. In winter months, El Niño storms or other high rainfall events may saturate soils and trigger slope failure.

**Deep-Seated Landslides**

Deep-seated landslides, ranging in depth from ten to several hundred feet, occur as a result of geologic and hydraulic changes, such as earthquakes or increased levels of groundwater. These landslides can move slowly or quickly and can cause extensive property damage, but rarely result in loss of life.

**Debris Flows Related to Shallow Landslides**

Shallow landslides may mobilize into rapidly moving debris flows and typically occur after sudden saturation of the ground. These types of debris flows are typically more dangerous because they move rapidly, causing both property damage and loss of life.

Debris flows may also occur as a result of post-fire conditions, where wildfires have left barren ground exposed to heavy rainfall. Intense rainfall, generally greater than .5 inch per hour, has the potential to trigger a post-fire debris flow. These landslides may impact lives and properties within the deposition zone and can result in downstream flooding. Post-fire debris flows often occur during the fall and winter following major summer fires.

**Location of the Hazard**

The susceptibility of an area to landslides depends on several variables, including magnitude of slope gradients, water content, ground cover, presence of erosion, and slope material and structure. However, landslides are most prevalent in terrain with weak material and steep slopes, and the highest risk is found in areas with high rainfall or high

earthquake potential. Slope failures are also most likely to occur in areas where they have occurred in the past. In California, the most landslide-prone areas are found along the coast and in the northern Franciscan Formation.

General landslide vulnerability can be estimated from the distribution of weak rocks and steep slopes as seen in Figure 8-11. Based on the Figure below, the CSU-East Bay campus is located between areas moderately susceptible to landslide.

Figure 8-11: Deep-Seated Landslide Susceptibility Surrounding CSU East Bay

Extent of the Hazard

In Hayward, landslides are more likely to occur in the hillsides east of CSU East Bay, which are susceptible to landslides as a result of rain or ground shaking. Seismic activity along the numerous Bay area faults may lead to landslides. The indirect impacts of landslides in the region may cover a larger geographical extent. Based on the campus’ close proximity to the landslide hazard zone, and the history of landslides on Alameda County, the planning committee ranks the extent of the landslide hazard for the campus as Moderate.

History of the Hazard

FEMA has declared nine major disasters involving landslides, mudslides, or mud flows since 1982. NOAA recorded fourteen debris hazard events in Alameda County from 2006 to 2019. The 1997-1998 El Nino storms caused abundant debris flow on the eastern hillsides of the county and approximately $400,000 in damage. No landslides have been recorded on, or immediately adjacent to the campus.

Potential Impacts of the Hazard

CSU East Bay may be impacted by the disruption of services as a result of landslides in the region. Landslides can result in physical damage to buildings and property and have the potential to significantly affect infrastructure. As a landslide moves, it distresses structural foundations by settlement, cracking, and tilting. Fast-moving flows can remove entire structures in one instance, while other types of flows can cause damage gradually.

Transportation and utility infrastructure are particularly vulnerable to landslides, since the failure of any component can disrupt service over a large area. The loss of power and communication and disruption of transportation can have cascading effects throughout an area, including impaired disposal of sewage, contamination of water supplies, and the release of flammable fuels. Transportation routes are also often expensive to clean up, and prolonged obstruction can disrupt the movement of people and goods for long periods of time.

Probability of Future Occurrence of the Hazard

Slope failures are also often triggered by other natural hazards, such as heavy rainfall or earthquakes, so landslide frequency is somewhat related to the frequency of these other hazards. As climate change impacts the frequency and intensity of triggers such as rain events, fires, and coastal erosion, landslides may generally occur more often. Historically, landslides have occurred frequently in the foothills and therefore are highly likely to occur in the future. The USGS has identified these foothills as a site where intense rainfall is likely to trigger a fast-moving downslope mudflow. Given the location of the campus adjacent to the landslide zone, and the historical occurrence of landslides in the county, the planning committee ranks the probability of the landslide hazard for the campus as Possible.

Vulnerability to the Hazard

The City of Hayward is susceptible to landslides associated with earthquakes and flooding. The vulnerability of the built environment to landslides depends on exposure and is more likely to incur damage as a result of proximity, rather than inferior structural design. The structures most vulnerable to landslides are buildings and utility/transportation lifelines, which can be impacted by either impact or ground deformation. Utilities and transportation infrastructure are particularly vulnerable, due to their geographic extent and susceptibility to physical distress. The CSU-East Bay campus may contain building and infrastructure vulnerabilities to some degree. See the landslide location map in relation to the campus along with landslide severity zones identified.
Campus leadership may decide to conduct a broader assessment of asset risk in the future. Finally, any population proximal to a landslide when it occurs is vulnerable to its impacts.

**Estimate of Potential Losses**

There are no current models for estimating potential losses from a landslide directly impacting the campus.

Although the economic impact of landslide damage can exceed that of the direct repair costs, there are currently no applicable methods for estimating indirect costs related to CSU East Bay.

**Vulnerability Assessment Conclusions**

Landslides could impact the campus in a variety of ways, primarily related to indirect impacts to transportation and utilities. Utility outages can impact health, particularly for vulnerable populations, and can cause interruptions in operations. Interruptions may impact student and employee’s ability to travel to campus and the delivery of classes and events.

**Identified Data Limitations**

The ability to predict future landslides at the CSU East Bay campus is limited. However, the USGS estimates that climate change-induced shifts in weather will increase the frequency of post-wildfire landslides, which are expected to occur almost every year in California.
**Power Outage**

**Description of the Hazard**

CSU East Bay is located in the eastern region of the San Francisco Bay along with the City of Oakland, Hayward, Fremont, Richmond, Berkley Emeryville, Alameda, and others. Most aspects of modern life, rely on the near continuous availability of utilities, such as electricity, water, and natural gas and the East Bay is no exception as it is a highly populated community with one of the Bay Area’s greatest population densities. An interruption in the supply or distribution of these services can leave highly populated areas, like the East Bay Area, without electricity or sanitation. These interruptions can produce cascading effects from other hazards, such as major windstorms, leading to intentional disruptions of transmission lines due to safety concerns.

A power outage event can interrupt day-to-day operations of the campus, like in-person classes, impede, or limit digital, telephonic or radio communications, create traffic jams around the busy avenues and boulevards surrounding the campus, close the student health center and close restaurants around campus and outside the campus. Additionally, thousands of CSUDH student residents in on-campus housing would also be affected by a power outage on campus and/or in the surrounding area.

An electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of **intentional** disruptions:

- Planned: Some disruptions are intentional and can be scheduled based maintenance or upgrading needs.
- Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.
- Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.
- Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

**Unintentional** or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

- Accident by the utility, utility contractor, or others.
- Malfunction or equipment failure.
- Equipment overload (utility company or customer).
- Reduced capability (equipment that cannot operate within its design criteria).
• Tree contact other than from storms.
• Vandalism or intentional damage.
• Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.
• Wildfire that damages transmission lines.

Location of the Hazard

Although power outages can take place within a certain area, it has the potential to affect the entire planning area equally.

Extent of the Hazard

An electric power disruptions and outages fall into two categories: intentional and unintentional.

The four types of intentional disruptions:

Planned: Some disruptions are intentional and can be scheduled based maintenance or upgrading needs.

Unscheduled: Some intentional disruptions must be done "on the spot" in response to an emergency.

Demand-Side Management: Some customers (i.e., on the demand side) have entered into an agreement with their utility provider to curtail their demand for electricity during periods of peak system loads.

Load Shedding: When the power system is under extreme stress due to heavy demand and/or failure of critical components, it is sometimes necessary to intentionally interrupt the service to selected customers to prevent the entire system from collapsing. These intentional interruptions result in rolling blackouts.

Unintentional or unplanned disruptions are outages that come with essentially no advance notice or warning. This type of disruption is the most problematic. The following are categories of unplanned disruptions:

Accident by the utility, utility contractor, or others.

Malfunction or equipment failure.

Equipment overload (utility company or customer).

Reduced capability (equipment that cannot operate within its design criteria).

Tree contact other than from storms.

Vandalism or intentional damage.

Weather, including lightning, wind, earthquake, flood, and broken tree limbs taking down power lines.

Wildfire that damages transmission lines.
In order to anticipate outage conditions and reduce impacts, campus facility managers and others keep track of conditions and data provided by the media, municipal utilities and the California Independent System Operator (CAISO) which is tasked with managing the power distribution grid that supplies most of California, except in areas served by municipal utilities. CAISO is thus the entity that coordinates statewide flow of electrical supply. CAISO uses a series of stage alerts to the media based on system conditions. The alerts are as follows:

Stage 1 - reserve margin falls below 7 percent.
Stage 2 - reserve margin falls below 5 percent.
Stage 3 - reserve margin falls below 1.5 percent.

Rotating blackouts become a possibility when Stage 3 is reached. Utility agencies aim to advise affected areas approximately 48 hours in advance of a potential PSPS event and will attempt notification again approximately 24 hours before power is shut off. Campus staff respond accordingly.

Given the prevalence of rolling blackouts and other power outages in California, the campus maintains safety precautions, situational awareness, access to emergency power generators and other protocols for managing campus power outages. Given that recorded outages have taken place on campus, the planning committee ranks the extent of the power outage hazard as Moderate.

History of the Hazard

CSU East Bay has experienced power outages for various reasons over time. The university worked with the community’s local electric utility company, Power, Gas and Electric (PG&E) to restore energy to the campus for its facilities, assets, resident halls, and classrooms.

A loss of power incident affecting the campus occurred on October 17, 2019, CSU East Bay was impacted by a PG&E mandated Public Safety Power Shut Off (PSPS) creating challenges for students, especially commuter students, making it difficult for students to get to the University. CSU East Bay is considered a commuter school, where a large majority of their students drive, at times hours, to get to campus. Mass power outages make it hard for commuter students to make it to their class on time and safely. With climate change related hazards, like wildfires, PSPS’s will continue throughout California when wildfire threats exacerbate in areas within proximity of the Bay Area, especially the East Bay.

Potential Impacts of the Hazard

Instructors, campus residents, staff and administration rely on electricity for basic survival and operations. During a widespread power failure, it may take days to restore operations. Electrical power may be the only cooling source for many individuals around the campus and its community, and long-term outages can potentially put people’s health and life at risk. Disruptions in the supply of heating fuel may put people and property at
risk during extremely cold weather if it relies on electric generation or heating mechanisms instead of gas. Additionally, many medical devices, communications devices, and security rely on power to maintain their functions.

Climate Change and Energy Shortage

Climate change is expected to bring more frequent and intense natural disasters. These changes have created a variability at a rate that makes historical data a poor predictor of future climate. For example, the warmest years on record in California occurred in 2014, 2015, and 2016. The 2016-2017 year broke the record as the wettest ever recorded in the northern Sierra Nevada Mountains.

Changes in temperatures, precipitation patterns, extreme events, and sea-level rise have the potential to decrease the efficiency of thermal power plants and substations, decrease the capacity of transmission lines, render hydropower less reliable, spur an increase in electricity demand, and put energy infrastructure at risk of flooding.

With climate warming, higher costs from increased demand for cooling in the summer are expected to outweigh the decreases in heating costs in the cooler seasons. Hotter temperatures in California will mean more energy (typically measured in “cooling-degree days”) needed to cool homes and businesses both during heat waves and on a daily basis, during the daytime peak of the diurnal temperature cycle. During future heat waves, historically cooler coastal cities (e.g., San Francisco and Los Angeles) are projected to experience greater relative increases in temperature, such that areas that never before relied on air conditioning will experience new cooling demands.

Secondary impacts of energy shortages are most often felt by vulnerable populations. For example, those who rely on electric power for life-saving medical equipment, such as respirators, are extremely vulnerable to power outages. Also, during periods of extreme heat emergencies, the elderly and the very young are more vulnerable to the loss of cooling systems requiring power sources.

Probability of Future Occurrence of the Hazard

The probability of California experiencing a power outage can be difficult to quantify but is a hazard that occurs annually during the same seasonal periods of temperature variance throughout the calendar year. Hayward and Alameda County experience such outages. As such, the probability ranking for the area is Likely; although the campus has most likely recorded fewer events than the surrounding area, it is prudent to assign this same ranking for the campus.

Climate models suggest summer global temperatures are likely to increase while changes between temperature extremes would be more pronounced. As such, it is expected that power outages will occur more frequently in the future.

Vulnerability to the Hazard

Based on the data available, and in consideration of the increasing effects of climate change, the campus remains vulnerable to power outages in terms of impacts to people,
power infrastructure and campus operations. Nonetheless, as discussed campus leadership works to reduce vulnerabilities through consistent use of safety and operational protocols and emergency power sources to ensure it is able to mitigate an interruption to electrical power.

Estimate of Potential Losses

The data provided by Cal State East Bay State does not report any value for potential losses due to power outage.

Vulnerability Assessment Conclusions

The primary concern for campus leadership is that a loss of power can lead to potential hazards to students, faculty, and staff at Channel Islands. Safety and operations protocols center on the following “direct impact” set of concerns:

Elevators, entry ways, air filtration systems and lighting provide the campus community with the necessary infrastructure and systems to function and navigate through the campus and to maintain a safe campus environment and visibility during nighttime hours. The vulnerable population (especially students with physical disabilities) may be the most heavily affected by loss of power as they rely on elevators, entry ways with automatic doors, and locks and lights may impede on a disabled student’s ability to travel and utilize the campus and its structures safely.

The use of communication devices, billing, records, and electrical tools may also become unusable due to a loss of electricity. Many records and billing items may have to revert to “by-hand” procedures and paper copies may be needed for continuity of operations. Additionally, classrooms may not be usable if lighting equipment is not functioning impacting a semester or quarter’s progress for the academic year.

Identified Data Limitations

Cal State East Bay did not report any monetary or life losses due to a power outage. Also, the campus did not report any incidents involving a power outage directly affecting the campus community and operations.
Volcano (Associated Air Quality)

Description of the Hazard

The US Geological Service defines volcanoes as “openings or vents where lava, tephra (small rocks), and steam erupt on to the Earth’s surface. Through a series of cracks within and beneath the volcano, the vent connects to one or more linked storage areas of molten or partially molten rock (magma). This connection to fresh magma allows the volcano to erupt over and over again in the same location.”

A volcanic eruption occurs when magma, lighter than surrounding rock, is driven upwards by its buoyancy and by pressure from the dissolved gases contained within it. Gases are released from magma as it reaches the surface and pressure decreases. Magma can be erupted in several ways and violent eruptions typically cause tiny pieces of tephra (ash) to be carried away by the wind. This ash is hard, does not dissolve in water, is extremely abrasive and mildly corrosive, and conducts electricity when wet. The gases released in an eruption include carbon dioxide, sulfur dioxide, hydrogen sulfide, and hydrogen halides. Depending on their concentration, these are potentially hazardous to people, animals, agriculture, and property.

Location of the Hazard

There are eight volcanic areas located throughout California. Seven of these - Medicine Lake Volcano, Mount Shasta, Lassen Volcanic Center, Clear Lake Volcanic Field, Long Valley Volcanic Region, Coso Volcanic Field, and Salton Buttes – are considered active volcanoes. No portion of CSU East Bay or Alameda County is located within a volcano hazard zone.

Extent of the Hazard

Volcanic hazards are most severe within a few miles of the volcano vent and the severity generally decreases with distance. Ash impact zones can range from tens to hundreds of miles from the vent source. The US Geological Survey has estimated zones surrounding active volcanoes wherein two (2) inches or more of ashfall following an eruption is possible. While CSU East Bay does not fall within an estimated ashfall zone, lighter dustings of ash outside of those areas may directly or indirectly impact the campus. As such, the planning committee ranks the extent of the hazard for the campus as Low.

History of the Hazard

No historical eruption events in California have affected the campus. Over the last 1,000 years, there have been at least 12 eruptions in California. The most recent volcanic

---

eruption in California occurred at Lassen Peak about 100 years ago, when a major explosion delivered windborne ash over 275 miles away.

Potential Impacts of the Hazard

The specific impacts vary widely and depend on which type of volcano erupts, the style of explosion, the volume of lava, the eruption duration, and the local water conditions. As CSU East Bay is not proximal to an active volcano, only the potential impacts of ashfall and gases have been detailed. While both these hazards can be widespread, their most severe impacts are generally seen closer to the volcanic source.

Although ashfall is typically a nonlethal volcanic hazard, it is the most widespread and disruptive. Falling ash can damage crops, electronics, and machinery. It can also impact human health by irritating the respiratory tract, eyes, and skin. The particles may enter drinking water and structures and may cause structure failure if it is thick and heavy enough. Even a fine layer of ash can disrupt utilities. A portion of California’s major electric transmission lines, aerial telecommunication lifelines, transportation corridors, and water storage and conveyance lie within the state’s volcano hazard zones. Impacts to any of these can impact operations at CSU East Bay.

The potential impacts of gases released during volcanic eruptions are as follows:

Carbon dioxide typically becomes diluted very quickly and is not life threatening. However, it can become trapped in higher concentrations in low-lying areas and has the potential to be fatal.

Sulfur dioxide can cause acid rain and air pollution downwind of a volcano.

Hydrogen sulfide can cause irritation of the upper respiratory tract. At high concentrations it can cause unconsciousness and death.

Hydrogen halides can coat ash particles and, once deposited, poison drinking water, agricultural crops, and grazing land.

Probability of Future Occurrence of the Hazard

The US Geological Survey, based on the record of volcanic activity in California, estimates that the probability of another small- to moderate-sized eruption in the next thirty years is about 16 percent. As such, the annual probability of future occurrence for the campus is ranked by the committee as Unlikely.

Vulnerability to the Hazard
